FULL-PAGE PLATES

	Facing page
LXXXI. Ray Peach (in color). <i>Frontispiece</i>	
LXXXII. Peony, Baroness Schroeder	2431
LXXXIII. An avenue of palms in southern Florida.— <i>Oreodoxa regia</i>	2446
LXXXIV. A plantation of papaya in the Hawaiian Islands	2462
LXXXV. Good pods of the garden pea, variety Peter Pan	2491
LXXXVI. The common garden geranium, a form of <i>Pelargonium</i>	2527
LXXXVII. A branch of <i>Pereskia aculeata</i> , one of the leaf-bearing cacti. (From a photograph by H. K. Sloat)	2547
LXXXVIII. <i>Picea canadensis</i> (or <i>P. alba</i>).—A golden variety	2616
LXXXIX. Planting.—Rhododendrons in a landscape composition (in color)	2659
XC. Bavay or Reine Claude (<i>Reine Claude de Bavay</i>), one of the Green Gage plums of American orchards	2716
XCI. Harvest scene in the potato country	2767
XCII. A plant of <i>Primula obconica</i>	2800
XCIII. <i>Prunus serrulata</i> var. <i>sachalinensis</i> .—The form Fugenzo	2832
XCIV. The bloom of <i>Pyrus pulcherrima</i> (<i>P. floribunda</i>)	2869
XCV. Radish, in several varieties (in color)	2898
XCVI. Rhododendron well placed.—One of the <i>Rhododendron catawbiense</i> varieties	2935
XCVII. A rock-garden	2969
XCVIII. <i>Romneya Coulteri</i> , the Matilija poppy, one of the most showy of California flowers	2978
XCIX. Rose.—White, Bride; pink, Bridesmaid (in color)	3000
C. Rose, American Beauty	3018
CI. Well-filled mixed border, with lilacs predominating (in color)	3043
CII. <i>Sambucus canadensis</i> , the American sweet or summer-flowering elder	3068
CIII. Greenhouse group of parent and hybrid <i>sarracenias</i>	3084
CIV. Seed-growing in California.—Drying and turning lettuce stalks on the sheets; cutting onion heads (Photographs by C. C. Morse & Co.)	3134
CV. <i>Solidago ulmifolia</i> , one of the common goldenrods	3187
CVI. Spinach.—A plant of Long Season variety; spinach field near Norfolk, Virginia.	3205

	Facing page
CVII. Effective shrubbery border.—Spireas in good form	3235
CVIII. Strawberry.—The Climax variety (in color)	3260
CIX. Sweet peas of the Spencer or waved type	3284
CX. Commercial field of sweet potatoes in the Middle South	3296
CXI. Syringa (lilac), Madame Lemoine	3325
CXII. A good type of commercial tomâto.—Brinton Best (in color)	3352
CXIII. <i>Tsuga canadensis</i> .—The hemlock spruce of the northeastern United States and Canada	3383
CXIV. Tulip varieties of the <i>Tulipa Gesneriana</i> type (in color)	3402
CXV. A market-garden of the modern type near a city, with overhead irrigation	3437
CXVI. <i>Viburnum tomentosum</i>	3458
CXVII. Victoria and nymphæa in a good setting	3480
CXVIII. <i>Washingtonia filifera</i> var. <i>robusta</i>	3506
CXIX. <i>Wisteria sinensis</i> in a striking effect	3517
CXX. Zinnia, Giant Yellow and Scarlet	3549

P

PACHIRA (native Guiana name). *Bombacaceæ*. A group of tropical American trees of variable size, some of which are known to be deciduous, all with striking showy flowers and exceptionally large fruits.

Calyx almost tubulose, mostly short, truncate; staminal column long, divided at the top into 5 short branches, each of which in its turn ends more or less regularly in 3 bundles of about 15 stamens, with unequal slender filaments; caps. dehiscent, rounded-depressed to elongate-oblong, 5-celled, each cell containing several seeds coated in fleshy tissue. Allied genera are *Bombax* and *Adansonia*; the first one differs in having the small seeds imbedded in the woolly inside lining of the caps. (whence their name of silk cotton trees), the latter (the African baobab) in its 5-lobed calyx. In *Bombax*, the arrangement of the stamens is distinct and their number much greater.—Over 30 species of *Pachira* have been listed, of which at least 3 belong to *Bombax*, 4 are synonyms, and among the remainder several are likely to be dropped on one account or another. Botanically speaking, only 7 species are well known, all of which may be distributed into 3 main groups. The fls. may reach 13 in. long with a spread of 9 in. in certain species; the petals are narrow and gracefully recurved in some cases, obovate and somewhat stiff in others. The color varies from a rich pink to white or pale brownish yellow, distinct shades occurring in every species. The digitate foliage also contributes to give the trees their peculiar appearance. As to distribution, *P. aquatica* is found all over Trop. Amer., 3 species are restricted to Cent. Amer., 2 to the W. Indies, and the others are natives of S. Amer. They are easily cult. under glass and prop. either by seeds or cuttings, but, on account of their large size, most species are hardly desirable for conservatories. One species, *P. insignis*, has edible seeds, alike in size and flavor to the chestnut and on which account it is sometimes cult. in Venezuela and some of the Lesser W. Indies. The seeds of *P. macrocarpa* are sometimes used as a cacao substitute; it is probably the xiloxochitl of the Aztecs, being still called by that name (jelinjoche) in Nicoya (Costa Rica).

A. Caps. globose-depressed, i.e., its diam. greater than its length. (*Brachycarpæ*.)

insignis, Savigny (*Carolinea princeps*, Linn. f.). A small tree: lvs. 5-7-foliolate, the lfts. glabrous, subsessile, oblong, 8-24 in. long; fls. 7 in. long, erect; calyx cup-like, short and broad; petals obovate, long-cuneate, crimson or dark purple, covered without with a thick brownish down; staminal tube short, the stamens not reaching the end of the corolla: caps. about 5 in. long by 7 in. diam. Trinidad and Lesser W. Indies; also in Venezuela. J.F. 3:295.

AA. Caps. ovate-rounded, its diam. more than half the length. (*Mesocarpæ*.)

B. Calyx covered with large, crater-like glands: fls. sessile.

pustulifera, Pittier. A small tree: lvs. 7-foliolate; lfts. briefly petiolulate, obovate, $4\frac{1}{2}$ -9 in. long, minutely tomentose beneath: fl. about 7 in. long; calyx stipitate, truncate, pubescent within and irregularly covered with large glands without; petals lacinate, pinkish, yellowish pubescent without; staminal tube short, pubescent, the stamens much shorter than petals: caps. 10 in. long by 8 in. diam. Costa Rica.

BB. Calyx smooth or with only a few glands at the base: fls. pedunculate.

macrocarpa, Schlecht. (*P. fastuosa*, Decne. *P.*

longifolia, Hort.). Fig. 2694. A small or medium-sized tree: lvs. 5-7-foliolate; lfts. subsessile or briefly petiolulate, oblong or obovate, $2\frac{1}{2}$ -8 in. long, glabrous: fls. up to 9 in. long; calyx stipitate, cuplike, smooth or nearly so; petals lacinate or linear, brownish to greenish pubescent without, pink to white or pale yellow within; staminal tube glabrous, the stamens about as long as the petals: caps. ovoid, 9 in. long by 8 in. diam. Cent. Amer., from Mex. to Costa Rica. B.M. 4595. G.C. III. 54: 325. J.F. 2:109, 110.

villósula, Pittier. A tree reaching 90 ft.: lvs. 5-7-foliolate; lfts. petiolulate, obovate or elliptic-lanceolate, 2-7 in. long, villous beneath: fl. up to 10 in. long; calyx funnel-shaped, truncate, ferruginose-pubescent outside; petals lacinate, pubescent on both faces, pinkish

2694. *Pachira macrocarpa*.

longifolia, Hort.). Fig. 2694. A small or medium-sized tree: lvs. 5-7-foliolate; lfts. subsessile or briefly petiolulate, oblong or obovate, $2\frac{1}{2}$ -8 in. long, glabrous: fls. up to 9 in. long; calyx stipitate, cuplike, smooth or nearly so; petals lacinate or linear, brownish to greenish pubescent without, pink to white or pale yellow within; staminal tube glabrous, the stamens about as long as the petals: caps. ovoid, 9 in. long by 8 in. diam. Cent. Amer., from Mex. to Costa Rica. B.M. 4595. G.C. III. 54: 325. J.F. 2:109, 110.

villósula, Pittier. A tree reaching 90 ft.: lvs. 5-7-foliolate; lfts. petiolulate, obovate or elliptic-lanceolate, 2-7 in. long, villous beneath: fl. up to 10 in. long; calyx funnel-shaped, truncate, ferruginose-pubescent outside; petals lacinate, pubescent on both faces, pinkish

within, rusty colored without; staminal tube long, pubescent, the stamens shorter than the petals: caps. ovoid, 7 in. long by 5 in. diam. Panama.

AAA. Caps. ovate-elongated, its diam. less than half the length. (*Dolichocarpæ*.)

B. Fls. hardly over 4 in. long.

púlchra, Planch. & Lind. A small tree: lvs. 7-foliate; lfts. briefly petiolulate, cuneate-oblong or lanceolate, glabrous: fl. about 4 in. long; calyx cup-like, tomentose-pubescent outside; petals linear-oblong, greenish pink within, tomentose and brownish without; staminal tube short, the stamens hardly as long as the petals: caps. not known. Ocaña Mts., Colombia.

BB. Fls. 10 in. long or more.

speciosa, Triana & Planch. A tree about 150 ft. high: lvs. 7-foliate; lfts. briefly petiolulate, cuneate-oblong, glabrous, 4-8 in. long: fl. about 10 in. long; calyx cuplike, brownish pubescent without; petals oblong, long-attenuated, yellowish white inside, minutely tomentellose outside; staminal tube long, pubescent without, the white stamens nearly as long as the petals: caps. not known. Colombia.

aquática, Aubl. (*P. grandiflora*, Tussac). A small tree: lvs. 5-7 (9)-foliolate; lfts. subsessile, obovate to elliptic-lanceolate, glabrous, 4-12 in. long: fls. 8½-14 in. long; calyx tubulose-truncate, often warty at the base; petals laciniate, more or less deeply pinkish or purplish; staminal tube long, the red or scarlet filaments about as long as the petals: caps. 7-15 in. long, 3-5 in. diam. Trop. Amer., including W. Indies. G.C. III. 40:308.—*P. aquatica* varies considerably according to the nature of the soil in which it grows and to its environment, and it is not unlikely that most so-called species described in horticultural reviews should be considered as simple varieties of the same. This species is the best known in the genus and its area of distribution is very extensive; its cult. in hothouses has been often attempted and it has lately been intro. in Fla. under the name of *P. insignis*. *P. stenopetala*, in Gt. 9:302, is probably a cult. form of *P. aquatica*.

P. alba, Walp., is evidently a *Bombax*. B.M. 4508. Generally speaking, there is a great confusion as to the identification of the several species, most of which are not represented even in the larger herbaria.—*P. minor*, Hemsl., known to us only by a poorly executed plate in B. M. 1412, may be a variety of *P. aquatica*.

H. PITTIER.

PACHYSTIMA (said to be derived from Greek, *pachys*, thick, and *stigma*; alluding to the slightly thickened stigma). Spelled also *Pachystima* and *Pachy-*

stigma. *Celastraceæ*. Ornamental woody plants sometimes grown for their evergreen foliage.

Low evergreen shrubs: branchlets somewhat quadrangular, verrucose: lvs. opposite, small, serrulate or entire, short-petioled, with minute deciduous stipules: fls. perfect, small, in few-fl. axillary cymes; calyxlobes, petals and stamens 4; ovary 2-celled, often only 1 cell developing into a small, oblong, 1-seeded caps.—Two species in the mountains of N. Amer.; allied to *Evonymus*.

These are low trailing or spreading shrubs with small evergreen foliage and inconspicuous reddish flowers followed by small dull-colored capsules. They are hardy with slight protection in the Arnold Arboretum, Boston, and are handsome dwarf evergreens for rockeries or rocky slopes; *P. Canbyi* forms a dense carpet and may be used as a border plant for evergreen shrubberies. They seem to grow in any well-drained soil. Propagation is by seeds or by layers; also by cuttings of half-ripened wood under glass, and *P. Canbyi* also by division.

myrsinites, Raf. (*Myginda myrtifolia*, Nutt. *Oreóphila myrtifolia*, Nutt.). Spreading shrub, to 2 ft.: lvs. broadly elliptic to oblong-obovate, slightly revolute at the margin and serrulate or almost entire, ½-1 in. long: fls. short-stalked, reddish: fr. about ½ in. long. May-July. Brit. Col. to Calif. and N. Mex.—Resembles the small-lvd. form of *Evonymus radicans*, but of more rigid and stiff growth.

Canbyi, Gray. Dwarf shrub with trailing and rooting branches, scarcely exceeding 1 ft.: lvs. narrow-oblong, occasionally obovate, revolute and usually serrulate above the middle, ⅓-¾ in. long: fl.-stalks filiform, longer than half the lf.; fls. reddish. April, May. Mts. of Va.—This is somewhat similar in habit and foliage to *Evonymus nanus*, but less vigorous and of more even and regular growth. Sometimes called ratstripper.

ALFRED REHDER.

PACHYCÈREUS (Greek, *thick* and *cereus*). *Cactaceæ*. Usually trees, more or less branched, with very definite woody trunks.

Flowers appearing during the day, with rather short tubes; petals short; stamens included; ovary and tube of fl. covered with small bracts bearing wool, hairs, and bristles in their axils: fr. large, burlike; seeds large and black.—The genus consists of 10 species segregated from *Cereus*. Confined to the drier parts of Mex. Cult. as for *Cereus* and related groups; see *Succulents*. This genus is closely related to *Lemaireocereus*, one of the several segregates of *Cereus*; *C. queretarensis*, Web., is *Lemaireocereus queretarensis*, Brit. & Rose, rather than a *Pachycereus* (see page 1836, Vol. IV).

chrysomállus, Brit. & Rose (*Pilocereus chrysomállus*, Lem.). Tree-like, with erect branches, reaching a height of 30 ft.: ribs in cult. plants 13: areoles with long hairs; radial spines 11-13, the upper ½ in. long, the lower twice as long; centrals 4, still longer; all the spines amber-yellow, becoming brown: cephalium terminal or sometimes unilateral, a foot long, woolly and setose. Mex.—The indications are that the plant in cult. under the above name is a true *Cephalocereus* and not the *Pilocereus chrysomállus* of Lemaire.

2695. *Pachycereus Pringlei*.

Columna-Trajani, Brit. & Rose (*Pilocereus Columna-Trajani*, Salm-Dyck). **TRAJAN'S COLUMN**. Treelike, attaining a height of 50 ft. and a diam. of over 2 ft., simple below: areoles large, elliptic; radial spines 10-12, the upper very short, the lower longest, nearly an inch long; centrals 2, the upper an inch long, the lower 4-5 in.; fls. about 2 in. long, scarcely projecting from the unilateral woolly and bristly cephalium. Mex. R.H. 1890, p. 129.—The specific name refers to the famous Trajan's Column.

marginatus, Brit. & Rose (*Cereus marginatus*, DC. *C. gemmatus*, Zucc.). Simple or branching at apex, 2-3 in. diam., with 5-6 obtuse ribs, which are woolly their whole length: spines short-conical, rigid, 7-9, all nearly alike: fls. brownish purple, about 1½ in. long; fr. globular and spiny. Mex.—Frequently used for hedges in S. Mex. The st. is often covered with a woody crust.

pecten-aboriginum, Brit. & Rose (*Cereus pecten-aboriginum*, Engelm.). This species is sometimes cult. but does not do well under glass. The large burry frs. used by the Sonoran Indians for hair-brushes are sometimes seen in museums and curio stores.

Pringlei, Brit. & Rose (*Cereus Pringlei*, Wats.). Fig. 2695. One of the cordon cereuses of N. Mex. Not so tall as *Carnegiea gigantea*, ribs, fewer, and fls. scattered. Not in cult. G.F. 2:65 (adapted in Fig. 2695).

J. N. ROSE.

PACHYPHYTUM (Greek, *thick plant*). *Crassulaceae*. Succulents, likely to be found in the under-glass collections of amateurs, and out-of-doors far South. See page 870, Volume II.

Cauliscent, more or less branched, with very thick lvs. which are often terete: fls. solitary or in second racemes; calyx deeply lobed, the lobes shorter than the corolla, and appressed to it; corolla 5-7-parted and not at all 5-angled; petals erect below, spreading above; stamens 10, the 5 alternating with the petals free from the corolla, the other 5 borne on the petals each usually with a pair of appendages at the base; scales broad: carpels 5, erect, free to the base.—About 7 species from Mex. *Pachyphytum* is usually included in *Cotyledon* but some recent American botanists keep the genus distinct. *P. uniflorum*, Rose, is a stout species usually woody below with green hardly glaucous terete lvs., appendaged stamens and acute calyxlobes, said to be cult. in shady courtyards at San Luis Potosi, Mex. *P. bracteatum*, Klotzsch (*Echeveria bracteosa*, Lindl. & Paxt.). This species has oblanceolate to spatulate thickish lvs. and a curved, finally erect, second raceme which is 12-18-fld.: its calyx is deeply campanulate with unequal lobes and a bright red corolla. Mex. B.M. 4951.

PACHYPÖDIUM (Greek, *thick foot*, alluding to the roots). *Apocynaceae*. About 15 remarkable succulent shrubs and trees of Madagascar, S. Afr. and Trop. Afr., a very few of which are mentioned in horticultural literature. They are grown with succulents, and prop. by cuttings. Frequently the trunk is much swollen: lvs. simple, in spirals; stipules represented by rigid spines; or, according to Stapf, the lvs. suppressed with the exception of a terminal rosette, and the spinous stipules crowded more or less irregularly on the swollen branches: cymes terminal, with few or many sessile or peduncled pink, white or yellow fls.; sepals 5; corolla salver-shaped, constricted at base, or funnellform to campanulate, 5-lobed; anthers conniving into a cone, with appendages longer or shorter than the pollen-bearing part, the structure complex. *P. Geayi*, Cost. & Bois. Tree, 30 ft. or more, with succulent cactus-like spiny trunk, branching at summit: lvs. in terminal tufts, long and narrow. Madagascar. R.H. 1907, p. 490. *P. namaquanum*, Welw. St. 5-6 ft. high and 9-15 in. diam., fleshy, tapering upward, tubercled and spiny: lvs. obovate-oblong to oblong, crowded in a little

crown at the top of the trunk: fls. reddish tinged yellow and green. S. Afr. G.C. III. 46:371, showing the strange plants in the wild. *P. succulentum*, DC. Tuberous at base, 1-2 ft. high, producing several somewhat branched sts., bearing lvs. scattered on long shoots: lvs. oblong-linear or linear, 1½ in. long, pubescent above; stipules spiny: fls. 1 in. or more across, the oblong lobes white and purple. S. Afr. L. H. B.

PACHYRHIZUS (Greek, *thick*, and *root*). *Leguminosae*. Climbing herbs bearing large tuberous roots often 6 to 8 feet long and weighing fifty to seventy pounds, which are used for food and as a source of starch.

Leaves pinnately 3-foliolate; lfts. stipellate, lobed, 3-4 in. wide: racemes with swollen nodes and fascicled pedicels, bracts and bractlets setaceous, caducous; calyx 2-lipped, limb as long as the tube, upper lip emarginate, lower lip deeply 3-lobed; corolla much exerted, petals subequal, keel obtuse; stamens diadelphous; anthers uniform; ovary sessile, many-ovuled; style long, circinate at the apex, bearded down the inner side below the very oblique stigma; pod large linear, turgid, deeply depressed between the seeds.—A genus of 3 or 4 species distributed throughout the tropics of both hemispheres. Blanco, *Flora de Filipinas*, describes and figures the roots as turnip-shaped. When young, the roots are palatable.

2696. *Pachyrhizus palmatilobus*.

A. Lfts. entire.

erösus, Urban (*Dolichos erösus*, Linn. *D. bulbösus*, Linn. *P. bulbösus*, Kurz. *P. angulatus*, Rich. *Cacara erösa*, Kuntze). **YAM BEAN**. Root tuberous: st. twining, shrubby, hirsute, becoming glabrate with age: lvs. pinnately 3-foliolate, often long-petioled; stipules deltoid or ovate-lanceolate, short; terminal lft. long-pedicelled, broadly cuneate at base, deeply or shallowly lobed in the upper half; lateral lfts. oblique, short-pedicelled, stipels subulate: racemes 6-12 in. long, long-peduncled, base often branching, branches ascending; calyx ¼ in., as long as the pedicel; corolla reddish, 1 in. or more long; pod 6-9 in. long, ½-¾ in. broad, 8-12-seeded, straight glabrescent. Tropics of both hemispheres. H.I. 19:1842.—Eaten both raw and boiled.

tuberösus, Spreng. **JICAMA**. Root tuberous, much larger than the above: st. twining, 10-20 ft. long: lvs. entire or obscurely sinuate: racemes densely fld.: pod 8-12 in. long, ¾-1 in. broad. Trop. Amer. H.I. 19:1843.—Young pods superior to many cult. beans in the absence of fibrous strings about the sutures of the pods; seeds said to be poisonous. Perhaps only a cult. form of the above species. The root is said to be a great favorite with travelers, as it quenches thirst and is nutritious. They are cut in thin slices and sprinkled with sugar. Two forms are recognized in Mex., one called *agua*, with a watery juice, and one called *leche*, with a milky juice. It is said that they

can not be distinguished except by tasting the root. To have good roots, the blossoms and seed-pods must be kept pinched off, for if they are allowed to mature the roots are not good. The roots mature in about 5 months and may be allowed to remain in the ground longer, as they become sweeter as the cold season approaches.

2697. *Pachysandra procumbens*. (Flowers $\times 1$. Leaves $\times \frac{1}{2}$.)

AA. *Lfts. lobed.*

palmatifolius, Benth. & Hook. (*Dolichos palmatifolia*, Moc. & Sessé). Fig. 2696. St. twining, glabrous or pubescent: lvs. pubescent, often long-petioled, pinnately 3-foliolate, terminal lft. broadly ovate, deeply 3-lobed, with lateral lobes often somewhat 2-lobed, lateral lfts. less deeply 2-4-lobed, lobes ovate, mucronate: fls. purplish, in long-peduncled racemes. Trop. Amer.—Not so common, root smaller and less cult. than the preceding.

P. L. RICKER.

PACHYSÁNDRA (Greek, *thick stamen*). *Buxaceae*. Perennial herbs or subshrubs of some value as ground-cover in shade for their more or less evergreen leaves.

Stems prostrate or ascending, 6-12 in. high, from rootstocks, scaly below: lvs. alternate, usually coarsely toothed, evergreen or deciduous, 3-nerved: spikes staminate above, with a few pistillate fls. at the base of each; staminate fls. with 4 sepals and stamens and a rudimentary pistil; sepals variable in the pistillate fls.; petals none; pistil 3-celled, 2 ovules in each cell, the 3 styles spreading, filaments thick, exerted, conspicuous, usually white: seeds smooth.—Two species known: of low and dense growth, with very early fls. attractive to bees, and masses of bright green lvs. Easily prop. by division in ordinary soils. Good for rockeries.

In the vicinity of Boston, *P. procumbens* is deciduous, and is desirable only from the feature of its curious flowers borne so extremely early in the spring. The foliage is of a dingy color and deciduous, whereas *P. terminalis* is a true evergreen with thick, glossy foliage forming a dense mat, making a very desirable low-growing cover-plant, succeeding admirably either in full sun or partial shade. The variety *variegata* is a very choice cover plant for ornamental effects. (J. Woodward Manning.)

procumbens, Michx. MOUNTAIN SPURGE, Fig. 2697. One foot high or less: lvs. ovate to obovate, 2-4 in. long: spikes of white or purplish fls. from the base of the sts. March-May. W. Va. to Fla. B.M. 1964. L.B.C. 10:910. B.R. 33. G.C. III. 55:335.

terminalis, Sieb. & Zucc. Smaller: lvs. obovate-cuneate: the small spikes of whitish fls. terminal. May. Japan. Var. *variegata*, Hort., with white variegated lvs., is in the trade.

P. coriacea, Hook.—*Sarcococca pruniformis*, Lindl.

J. B. S. NORTON.

PACHÝSTIMA: *Pachistima*.

PACHÝSTOMA (Greek, meaning *thick mouth*, referring to the thick lip). *Orchidaceae*. Terrestrial orchids with leafless scapes from underground nodose rhizomes: pseudobulbs producing 1-2 lvs.: sepals and petals similar, the lateral sepals occasionally forming a chin, all upright; labellum 3-lobed, forming a sack with the base of the column; anthers bent over; pollinia 8, lying in pairs and bound into 4 by elastic threads. About 10 species, chiefly E. Indian and Malayan, but 1 from Trop. Afr. *P. Thomsoniana*, Reichb. f. (*Ancistrochilus Thomsonianus*, Rolfe), is the most commonly cult. species. It has large fls. with white sepals and petals, and the lip has green erect side lobes thickly dark purple-spotted and a narrow recurved midlobe which is white nearly covered with deep purple lines. Trop. Afr. B.M. 6471. J.H. III. 51:147. G.C. II. 12:582 (note), 624, 625; 18:501. Gt. 30:1061.—A warmhouse plant. *P. Thomsoniana* is now referred to *Ancistrochilus* by Rolfe. *Ancistrochilus* has 2 species and is readily distinguished from *Pachystoma* by the pollinia being united to a single stipitate appendage as well as by the remarkable lip and spreading segms.

PACHYSTRÔMA (Greek for *thick layer*). *Euphorbiaceae*. The one species, *P. ilicifolia*, Muell. Arg., is a shrub or tree of S. Brazil rarely cult. and chiefly in botanical gardens; the oily seed has been used in medicine. Juice milky: lvs. simple, pinnately veined, spinulose dentate: fls. apetalous; sepals valvate or slightly imbricate; stamens 3; styles 3, undivided; ovules 1 in each cell of the ovary. Related to *Manihot*.

J. B. S. NORTON.

PACKAGES for horticultural produce. The choice of a package and the method of packing horticultural products are very important considerations to every grower who is interested in establishing a reputation for his goods. The commercial value of well-grown produce of choice varieties may be greatly lessened or utterly destroyed if the attempt is made to market it in poor uninviting packages, or if it is poorly packed. Inferior produce or poor varieties are sometimes sold for prices above their real value when packed in an extra attractive way.

2698. A good pack of apples in a box-tray.

The choice of a marketing package for horticultural products is based largely on customs. These customs have developed gradually along with the growth of the industry in any special region, and when suitable and valuable they persist and become firmly fixed for the

2699. Well-packed and not packed dessert apples.

crop in that section. However, the supply of the raw material and the possibility of securing large quantities of it at a low price are important considerations besides custom. Examples of the custom of adopting a special package in a certain region might be cited, as barrels for apples in the eastern states, boxes in the western states. Peaches are generally packed in flat boxes in the western orchards, and each fruit is wrapped in paper; the same varieties of peaches are marketed from the southern states in six-basket carriers and the fruits are not wrapped, while from Michigan the same variety may be shipped in bushel baskets and from New York orchards in the Delaware type of basket. In general, it would not be advisable to pack any crop in a way that would widely violate the general

2700. Sizing machine.

custom of the community, unless the grower has a special market to receive his produce prepared in his special way.

The illustrations accompanying this article (Figs. 26-2718) show some of the diverse forms of packages for fruits and vegetables now in use in North America. The methods of packing cut-flowers are discussed in the article devoted to that subject, pages 922-925, Volume II. The separate fruits may also be consulted under their alphabetic entries.

Apples (Figs. 2698-2704, to show the classes only).

Since the beginnings of commercial apple orcharding, the barrel has been regarded as the standard package for the holding and shipping of apples. The size used has varied at different times and in different sections.

The size now specified by the United States Government as standard for apples is, when measured without distention of its parts: Length of stave, 28½ inches; diameter of head, 17½ inches; distance between heads, 26 inches; circumference of bulge, 64 inches outside measurement; representing as nearly as possible 7,056 cubic inches. Barrels for apples have been in favor for many years, and promise to remain so, for the reason that they are cheap, easily secured in most regions, can be readily handled

2701. Machine for sizing fruit

and easily and quickly packed, and the trade has become thoroughly accustomed to them.

The bushel box has been the standard package for apples in the western United States since apple production has been of commercial importance in those regions. The box is occasionally used by growers in the eastern apple regions. Formerly its use was always associated with fancy grade high-quality fruit. Western fruits shipped to eastern markets were of this class and always came in boxes. Some eastern growers thought that if even ordinary grades and quality of fruit were packed in bushel boxes, the attractive prices that were secured for western fruit could be secured upon the reputation of the package. The delusion was not long-lived.

As compared with the barrel, the box is a more attractive package, more easily handled, shipped and stored. It is easier to sell from in a store or on a fruit-stand, and when the apples are closely sized, the exact number in every package is known, and they are of

2702 A sizer

uniform size, and this is of value to dealers and restaurant-keepers.

Boxes cost about one-third as much as barrels, and they hold about one-third as much, but more time is required properly to pack three boxes with apples than to pack one barrel properly. The Government stand-

2703. Another form of sizer.

ard bushel box for apples is 18 by 11½ by 10½ inches, inside measurement. There are various styles, those used in the western states being made with solid ends, and two pieces each for the top and bottom, and one piece for the sides. In the East, where the box is used, panel ends instead of solid pieces are used; otherwise the same as the western style.

Apples are usually packed into barrels in the orchard, but sometimes may be carried to a packing-house or shed. A common way is to empty them from the picking-bag or -basket upon a packing- or sorting-table. From this pile, the "facers" are selected. These are fruits of a uniform size and should be of such a color as will honestly represent the average of the crop. The facers are then laid by hand in the then bottom, but later top, of the barrel. Sometimes two layers are placed in by hand. The barrel is then filled by emptying the apples from a basket that can be lowered into the barrel, or emptied from the apron attached to the lower end of the table. The barrel should be frequently "racked," i. e., given several short, quick, vigorous shakes, to settle the fruit and cause one to roll or slip over the other and thus become firmly lodged. When the barrel is well filled, a layer of apples is placed by hand on top. This operation is known as "tailing," and the cover is pressed into place and held there by driving the hoops down toward the larger part of the barrel, and sometimes by nailing.

2704. A lined picking-basket, for apples, pears and other tree-fruits.

2705. Bamboo basket for shipping citrus fruits in the Philippines.

Appliances or machines to size the fruits are used when apples are packed in bushel boxes, and with the recent enactment of laws in several states requiring that the minimum size of the fruits be marked upon the package this becomes necessary when packed in barrels. This sizing may be done by the eye and hand or with the aid of a sizing-board, but for rapid work a machine is necessary. There are a great many kinds, and new styles are manufactured and

offered for sale every season. (Figs. 2700-2703.) These machines are shown not necessarily for recommendation but to illustrate some of the types.

Grading is the operation of selecting the fruits that are similar in appearance and value. No machine can do this; it must be done by hand. Grades are variable, depending upon the general crop of the season, the ideals of the packer, and the governmental requirements. Usually there is a "Fancy," "Grade A," and "Grade B," or, it is frequently designated as "Fancy," "Standard," and "Choice."

The art of properly packing the graded and sized apples in the bushel box requires skill and practice. There are well-known standardized ways of doing this work. Details of this operation may be found in Cornell Bulletin No. 298.

Apples are also packed in one-bushel hampers, a commonly used package for summer varieties in the Atlantic Coast states, and also in peck and one-half-bushel market baskets (Fig. 2699), and peck crates.

It is always necessary to exercise the greatest care in the picking of the fruit and in handling it from the

tree. A good lind picking-basket, with swing handle, is shown in Fig. 2704.

Citrous fruits.

Citrous fruits are cut from the trees with shears. Care always should be taken to make a smooth clean cut, as any injury to the skin or a long stem that may puncture a fruit that it comes in contact with may lead to serious decay. The picked fruit is placed in a bag, or sack, or basket, and, when filled, this is emptied in a "picking," "field," or

2707. Six-basket crate. Used for tomatoes and peaches in Georgia and Florida.

"lug-" box. It is then hauled to the packing-house, where it is graded by skilled workmen and then carefully sized. The different sizes are packed into standard-size boxes. The orange box, which is made of wood and is 12 by 12 by 26 inches outside measurement, with a partition in the center, may hold from 40 to 600 fruits, but the common sizes are 96, 112, 120, 150, 166, and 200.

Lemons are very carefully graded and sized by hand. A lemon box has outside measurements of 11 by 1½ by 27 inches and holds from 180 to 540 fruits, but the most common and valuable sizes are 300 and 360 fruits.

Pomelos, commonly called grapefruit, are handled in a similar way and packed in the same kind of package as is used for oranges.

In a few cases, half-boxes of all these fruits are packed. All citrus fruits are wrapped in tissue paper.

In Fig. 2705 is shown an interesting native basket or hamper in the Philippines. (Wester.)

Cherries.

Cherries are hand-picked from the tree with

2706. Delaware peach basket.

2708. Berry crate holds thirty-two boxes.

the whole stems adhering to the fruit, or the stems are cut with shears; rarely, when the fruit is to be canned soon after picking, it is pulled from the stem. In this case it is carried to the canning plant in boxes which are lined with newspapers.

2709. Portable hinged crate

bottom layer is carefully placed in by hand and enough fruit to make a firm tight pack distributed over the bottom layer, and the cover pressed on.

Grapes.

Grapes are cut from the vines with special grape shears. Fine varieties for fancy market are handled with care, so as not to rub off the bloom. They may be packed in the shipping package in the field, but are usually carried to the packing-house in trays. Some growers prefer to hold them in the packing-house for a day or two, to allow the stems to "wilt," as they can

2710. A vegetable basket.

2711. Bushel basket with cover, useful for vegetables and hard fruits.

then be more easily handled. The packing is usually performed on a table or bench, and from the picking-box or tray into the shipping package.

The most common package is a five-, eight- or ten-pound Climax basket with a solid wooden cover. Grapes intended for wine are marketed in peck or half-bushel baskets, and in New York flat trays are commonly used.

Pears.

Pears were formerly packed in a small barrel or keg holding about five pecks, and more recently pear barrels were commonly used. These held about a peck less than the standard apple barrel. The packages now used are the standard barrel and the bushel box, the same as the apple. When the box is used, each fruit is wrapped in paper.

Pineapples.

Pineapples are packed in crates that hold two dozen fruits, and each one is wrapped in paper.

2712. A bushel box. Useful for fruits and vegetables.

Peaches.

Peaches are picked into baskets of various types, the one-half bushel swing-handle type being the most common, and are carried to the packing-house. In some regions the fruits are run over mechanical sizing ma-

chines, similar to apples, or sized by hand. They may be packed for shipment into flat twenty-pound wooden boxes, and each fruit wrapped in paper. This is the general custom in the western states. In the eastern states the stovepipe or Delaware basket (Fig. 2706), holding sixteen quarts, is used. There may be a slat cover or netting cover, and a light crate that will hold three of these baskets is sometimes used.

The six-basket Georgia carrier is a standard peach package (Fig. 2707). It requires special skill to pack fruit into these baskets properly and rapidly. The half-bushel and bushel baskets are also well recognized peach packages. A round stick placed in the center of the package to support the cover insures a minimum amount of bruised fruit.

2713. Ventilated barrel.

Plums.

Plums are shipped in a great variety of packages. Fancy grades are wrapped in paper and packed in two-quart baskets and four of these are held in a flat wooden box or crate that weighs about twenty pounds. Large fruit varieties are wrapped in paper and packed in flat twenty-pound boxes the same as peaches. Climax baskets, holding from five to twenty pounds are used, also half-bushel and bushel baskets. Small-fruit varieties, like the Dawson, may be shipped in sixteen-quart cases.

Small-fruits (Figs. 2708, 2709).

The berry-like fruits, as blackberry, currant, dewberry, gooseberry, loganberry, raspberry, and strawberry, are almost universally packed in the sixteen-quart crate. In the past, these fruits, especially the strawberry, have been marketed in a great variety of packages, but in recent years the sixteen-quart crate

2714. A good commercial method of packing cauliflowers for special trade.

has rapidly become the standard and widely recognized package.

This package is also commonly used for the small-fruit plums, especially Damsons, and for cherries, both sweet and sour.

The quart boxes are often taken into the field and "picked into," and then carried to the packing-station and placed in the case; or the fruit pickers use a special picking-basket or -box, and this is delivered to the packing-station and the quart boxes filled there, where

the fruit may be graded and the work of the pickers examined.

Cranberries are picked from the vines by special machines or by hand, and packed in barrels. Occasionally twenty-pound wooden cases are used.

Vegetables (Figs. 2710-2718).

Packages used for the shipment of vegetables are not so evenly standardized as those used for fruits. Custom, however, seems to be of about the same importance, for similar vegetables grown in different regions are packed in different ways.

Asparagus is cut and tied in bunches of various sizes. In a few sections the loose stalks are packed in small boxes or crates, but the usual form is a "bunch," and these bunches are packed in any handy-sized box.

Hamper baskets holding from twenty-eight quarts to one and one-fourth bushels are commonly used for packing beans, corn, cucumbers, lettuce, peas, radishes, spinach, sweet potatoes; but a variety of packages is used for some of these products and for most of them ventilated barrels are used.

Beets are packed in crates, the same as cabbage.

Brussels sprouts are shipped in quart boxes like small-fruits, and these are placed in cases holding thirty-two, forty-eight or sixty quarts, the forty-eight-quart size being the most common.

Field-grown cauliflower is packed in ventilated barrels; the greenhouse product is packed in small flat boxes or trays that will hold six heads (Fig. 2714).

Packages for shipping celery are of many kinds. Each producing district has its own packages. A common one is a slat crate that varies from 6 by 8 by 24 inches to 10 by 26 by 24 inches. The plants, after being trimmed, are packed upright in these crates, which may or may not be lined with paper. With a fancy product, each bunch is wrapped in paper. A tight flat box, holding twenty-four or more bunches, is frequently used for express shipments.

Cucumbers are packed in baskets (Fig. 2715), hampers, flat boxes, and barrels. Lettuce is packed in barrels,

is wrapped in paper. Special retail packages for celery and sweet corn are shown in Figs. 2717 and 2718.

Onions are shipped in bags holding two bushels, in slat crates holding one bushel, in half-barrel hampers, and various other types of packages, and also in bulk.

2716. A twelve-melon package, used for the small dessert varieties.

Potatoes are commonly shipped loose in a box-car. In cold weather, the car must be lined with paper and a heater in each car keeps them warm enough to prevent freezing. In some sections, the practice is to use bags holding about two bushels. Barrels are frequently used. Ventilated barrels are commonly used for sweet potatoes. Special baking potatoes from some regions are wrapped in paper and packed in bushel boxes. Squash is usually packed in ventilated barrels. Sweet potatoes from New Jersey are packed in hamper baskets; those grown in Virginia, in barrels.

Tomatoes are packed in flat boxes, Climax baskets, six-basket Georgia peach-carriers, and hamper baskets. They may or may not be wrapped in paper. For local markets, a great assortment of packages are used, but the peck and half-bushel market basket is the most common.

H. J. EUSTACE.

2715. Basket-packed cucumbers, for a home trade.

hampers, and frequently in crates 16 inches wide, 23 inches long and 8½ inches deep. Such a case will hold two dozen heads of No. 1 or two and one-half dozen heads of No. 2.

Muskmelons are packed in Climax baskets, flat boxes (Fig. 2716), and crates. Sometimes each melon

PÆDERIA (Latin, *pædor*, bad smell, referring to *P. fetida*). *Rubiaceæ*. Tropical shrubby twiners.

Slender twining plants, fetid when bruised, with terete flexuous branches: lvs. oppsite, rarely in whorls of 3, petioled: fls. small, mostly reddish or whitish, in axillary and terminal dichotomous or trichotomously branching paniced cymes, with or without bractlets; corolla tubular or funnel-shaped; throat glabrous or villous; lobes 4-5, valvate, with crisped margins, often 3-lobed at apex: fr. a small berry. Distinguished from allied genera by the 2-locular ovary and 2 capillary twisted stigmas.—Species about 25, India, Burma, Malay Archipelago, China, Madagascar, Mex. to Brazil. They are little known in cult., the following being a warmhouse climber. It is sometimes known as Chinese fever-plant.

fetida, Linn. Glabrous or nearly so: lvs. long-petioled, ovate or lanceolate, base acute, rounded or cordate: fls. pink, the cyme branches opposite: fr. broadly elliptic, much compressed: pyrenes black, with a broad pale wing, separating from a filiform carphophore. India, Malaya.—Oliver writes that it is

LXXXII. Peony, Baroness Schroeder.

"usually grown as a stove and greenhouse climber, but it is harder than is generally supposed. It is rather an attractive-looking but not free-blooming vine. The leaves, or any part of the plant, when bruised emit a most offensive odor. Cuttings should be put in any time after the growths are matured."

P. Wilsonii, Hesse. A strong climber from China, with hairy branches: lvs. long-petiolate, ovate-lanceolate, to 6 in. long; fls. cream-white with a purple-red eye, less than $\frac{1}{2}$ in. across, in a cluster somewhat like that of the lilac; corolla-tube $\frac{3}{8}$ in. long. This species stood two winters at the Arnold Arboretum, Boston, and blossomed, but was finally winter-killed.

L. H. B.

2717. Basket-packed celery, for home trade.

PÆDERÛTA (from *pæderos*, a name applied by the ancients to a species of *Acanthus*). *Scrophulariææ*. Hardy perennial herbs suitable for garden use: low, many-stemmed, puberulent or pilose, with opposite serrate or cut lvs. and dense terminal spikes: fls. short-pedicelled, solitary in the axils of small bracts; calyx 5-parted, the segms. narrow; corolla with a cylindrical tube and a sub-2-lobed limb, the lobes erect or erect-spreading; stamens 2, affixed to the tube: caps. acute, turgid. About 5 species, Eu. and the Orient in the mountains. By some considered a section of *Veronica*. The following species, which though perennial are usually treated as annuals, require a dry situation and light sandy soil. Prop. by seed. *P. Ageria*, Linn. Plant puberulous, 6-12 in. high: lvs. all acute, the lower ovate, middle ones $1\frac{1}{2}$ in. long, almost 1 in. broad, the upper longer and narrower-lanceolate, cut-serrate: fls. yellow, in short compact spikes; corolla nearly $\frac{1}{2}$ in. long with erect segms. May. Eu. *P. Bonarota*, Linn. Plant pilose, 4-6 in. high: lower lvs. orbiculate; upper lvs. ovate or lanceolate, serrate or cut; fls. blue, in compact globose or oblong spikes which are $1-1\frac{1}{2}$ in. long; corolla $\frac{1}{2}$ in. long with somewhat spreading segms. May. Eu.

PÆONIA (after the mythical physician Pæon). *Ranunculææ*. PEONY. PINEY. PÆONY. Specially attractive and important flower-garden perennials, prized for the showy spring and early summer bloom.

Herbaceous or woody: roots thickened to form upright rootstocks: lvs. large, alternate, pinnately compound or dissected, mostly ternate: fls. terminal and mostly solitary, but sometimes several, a very few species yellow, but mostly red, purple or white; sepals 5, persistent; petals conspicuous, broad, 5-10, but doubling may take place in any species; stamens numerous: carpels 2-5 on a fleshy disk, becoming dehiscent; follicles bearing the indurated more or less conspicuous style; seeds large, fleshy.—Species about 25, Eu. and Asia, and one small-fl. species (*P. Brownii*) in Calif. and northward. Peonies are among the dozen commonest and best hardy herbaceous perennials. By variation and hybridization, the garden forms are now very many. A botanical monograph, by E. Huth, is in

Engler's Jahrbücher, Vol. 14 (1891). An account by Baker, from which much of the recent botanical characterization is drawn, appears in G.C. II. 21, pp. 732, 779, 828, and Vol. 22, p. 9 (1884). See also R. Lynch, Journ. Roy. Hort. Soc. 12:428 (1890). According to Peter Barr, every species mentioned in Index Kewensis had been intro. to cult. in Eu. except *P. obovata*, a native of Manchuria; this species, once intro. but long ago lost, has very recently been brought again into horticultural notice.

It is customary to divide the genus into two groups, one including the herbaceous species and the other (chiefly *P. suffruticosa* or *P. Moutan*) comprising the woody kinds. This division is not invariable as the plants grow under cultivation, and to the horticulturist who wishes to distinguish the stem-species it is confusing. It may be better from the modern gardener's point of view to make the primary divisions on color of the flowers, into the red-white species and the yellow species. The yellow-flowered species have played a small part in the evolution of the cultivated forms, although *P. lutea* is now beginning to contribute a strain, and other yellow species are very promising. The species are difficult to distinguish, even in unmodified forms, and the garden forms are very puzzling to a systematic botanist. The confusion is increased by the use of Latin names for many of the garden varieties. No two systematists could be expected to agree on the limits and nomenclature of species. The following descriptive account is a compromise arrangement of the species.

As with most important genera of a considerable number of members, only a few species are in general cultivation and the others are known mostly only to amateurs and collectors. From the cultural point of view, there are two groups of peonies,—the shrubby or "tree" peonies, and the herbaceous peonies. The former are the product of *P. suffruticosa*, although the woody section has been extended lately by the addition of *P. Delavayi* and *P. lutea*. The Moutans are low shrubs, branching near the ground and bearing many large flowers in shades of red and running to white and even yellowish. This group is now much eclipsed by the popularity of the herbaceous kinds, which bloom

2718. Paper packages or cartons for sweet corn, and other vegetables supplied direct to consumer.

each year on shoots that arise from the crown, the plant dying completely to the ground on the approach of winter. These garden forms are probably the issue of different species, as *P. officinalis* of Europe and *P. albiflora* of Siberia and the far East. The set derived most directly from the former species are mostly earlier-flowering than those from *P. albiflora*. The botanical parentage of the horticultural herbaceous peonies needs

to be worked out from living material combined with a study of the historical development. It is commonly understood, however, that the present race of herbaceous peonies is mostly the progeny of *P. albiflora*, but many are from *P. officinalis*. The importance of the shrubby or tree peonies is not now

great, at least not in this country. The species, *P. suffruticosa* was formerly prized for its bushy habit and wide range of flowers both single and double. The varieties of this species were once commonly propagated by grafting them on the fleshy roots of the herbaceous species. Non-blooming shoots are chosen as cions, and the

2719. One of the modern type of herbaceous peony.

union is made in late summer, the tuber and its cion then being handled through the winter in a frame, to be ready for planting out in the spring. A yellow-flowered shrub-peony is lately offered by Lemoine (La Lorraine) as a cross between *P. lutea* and *P. suffruticosa*. This bloomed first in 1904; it was awarded a prize in Paris in 1909. The flowers are soft sulfur-yellow with a salmon tinge when opening, becoming lighter when fully open.

The herbaceous peony has come into great prominence in recent years. In this country, the merits of the plant have been recognized by the organization, in 1903, of the American Peony Society. This Society has now begun the publication of bulletins. It early undertook the study of varieties in a systematic way, coöperating in an extensive test at Cornell University, Ithaca, New York. The test-grounds and the studies corollary to the work, under the leadership of the late Professor John Craig, have yielded four publications: "Peony Check-List," by Coit, 1907; "The Peony," by Coit, Bulletin No. 259, Cornell Agricultural Experiment Station, 1908, in which is given an historical account of the peony, description of the species, and bibliography, as well as cultural advice; "Classification of the Peony" [varieties], by Batchelor, Bulletins Nos. 278 and 306, 1910 and 1911. The reasons for the popularity of the modern race of herbaceous peonies is given by Coit to be the ease with which they are grown, hardiness, permanence in the garden when once established, large size and wide range in color and form of the very showy flowers, fragrance of many of the varieties, freedom from disease and insects, usefulness both for cut-flowers and for landscape effects. As to season of the stem-types, he writes that it is begun, at Ithaca, "about the middle of May by *P. tenuifolia*, and carried along by the well-known old double red peony (*P. officinalis* var. *rubra*). Then come the tree peonies (*P. Moutan* [*P. suffruticosa*]) and, before they are gone, the earlier varieties of the Chinese peonies (*P. albiflora*). Somewhere near July 14, the blooming season closes with the latest varieties of the albiflora group."

The garden herbaceous peonies. (Wm. A. Peterson.)

Herbaceous peonies (Figs. 2719-2722) are among the most hardy, showy, and easily grown of all garden flowers. They stand the severe cold as far north as Duluth without any ground covering. In the southern states their growing season is so extended that they do not develop as fine blooms.

In delicacy of tint and fragrance, the peony more nearly approaches the rose than any other flower. The

old-fashioned early red "piny," cultivated since the time of Pliny, is still a favorite in our gardens. Nearly all of the many hundred named varieties grown at present have been obtained by crossing the various forms of *P. albiflora*. Of the great host of double varieties, nearly all have been developed since 1850. The single-flowering sorts are not so popular as the doubles. They do not seem to keep so long when cut, and fade more rapidly when on the plant.

Propagation of herbaceous peonies.

The easiest and most satisfactory method of propagation is by division of the large, thick roots. The roots may be lifted and divided any time from the middle of August until the stalks appear again in the spring. The best time, however, is in early autumn, when the cut surfaces soon callus over and new root-lets form before the frost sets in. Choose a large stool, cut off the leaves and separate into as many divisions as can be made with an eye to each tuber. In digging, care should be taken that all of the tubers are dug up, for if not they may remain dormant a season and then produce a shoot, giving rise to the many stray plants frequently found in old beds. Tubers divided without an eye should also be planted, as they often act in a similar way and make a showing above ground in two years' time. Peonies, like most tuberous plants, when dormant stand considerable exposure and can be shipped long distances with safety.

Grafting is resorted to in herbaceous peonies when new and rare varieties are to be rapidly increased. An eye of the desired sort is inserted into the tuber of some strong-growing variety, from which all the previous eyes have been removed. This operation is usually performed in August. The grafted plants should be placed in frames for the winter and transplanted the next year into nursery rows.

Propagating by seed is somewhat tedious, and is employed only for increasing distinct species and for obtaining new varieties. The seeds should be gathered as soon as ripe and kept damp until sown in November. A mulch the first season will keep the ground moist and prevent weeds from growing. Usually two years are required for the seed to germinate and three more before a well-developed bloom can be expected.

Soils and culture.

Peonies grow in all kinds of soil, but do best in a deep, rich, rather moist loam. A clay subsoil, if well drained, is very beneficial when blooms are desired, but the tubers ramify more in lighter soil if grown for propagating purposes. In preparing the bed, trench the soil thoroughly 2 or more feet deep, working in a great quantity of well-rooted cow-manure, as the plants are gross feeders. The ground should be kept well tilled, and an annual top-dressing put above the plants in November; this should be forked into the earth the next spring. They should have a liberal supply of water at all times, and especially while in bloom. Liquid manure, when applied in the growing season and at a time when the ground is dry, gives good returns, both in the growth of the plant and size of the bloom.

The eyes should be set 2 inches below the surface. In transplanting, it is a good plan to remove all the old

2720. A modern herbaceous peony of good habit.

earth so as to start with fresh unimpoverished soil next to the roots. The flowers produced on small divided plants are likely to be imperfect, but when thoroughly established a plant will continue to bloom if undisturbed for upward of twenty years. During the period of blooming an inconspicuous wire support is desirable, as a heavy rain often beats down the flowers.

The host of ancient and modern varieties available, ranging from purest white to deepest crimson, in such a diversity of form and size, afford great opportunity for the making of extensive color schemes. Peonies do fairly well in partial shade, which prolongs and intensifies the color of the bloom, and therefore may be used to advantage to brighten up somber nooks. The period of blooming for herbaceous peonies ranges from the middle of May through June. They grow 1 to 4 feet high and are therefore suitable for planting in front of shrubbery, along driveways, and are especially pleasing when entering into a distant vista. The richly colored shoots, which find their way up through the soil in the early spring, have considerable value for striking effect. When planted in a border with fall-blooming perennials, such as phlox and funkia, their rich glossy foliage is very effective. The old flowers should be cut off, so that no unnecessary seed follicles will be formed, and thereby exhaust the plant. It is important to remove the faded foliage on all peonies in November so that it may not interfere with the next year's shoots.

Because peony buds admit of being shipped long distances without water, and arrive in good condition, they are now used very extensively on Decoration Day and for June weddings. When cut in tight buds and closely wrapped in paraffin paper, some varieties can be held in cold storage for over a month and then open up very satisfactorily.

For forcing, lift the plants in September and place in a coldframe where they will be accessible when the time for forcing arrives. When brought under glass, a uniform temperature of 55° to 60° should be maintained. By feeding well with liquid manure, strong blooms can be produced in eight weeks. A two years' rest is necessary before the plants are forced again. To secure extra-fine blooms on double-flowering varieties, remove the lateral buds as soon as formed. When the first lateral bud is retained instead of the terminal one, a later period of blooming is secured.

Diseases. (A. C. Beal.)

Among the peony diseases, the most prevalent and destructive is the botrytis blight, which attacks the stems, buds, and leaves. Early in the spring the young stems are attacked at the surface of the ground. The tissue turns black, and later the stems wilt and fall over. Sometimes this trouble is seen as late as the following season. The use of green manure appears to favor the attacks of the disease, and only well-rotted manure or mineral fertilizers should be employed. Later, the young flower-buds are attacked, and these turn black and dry up. This is the so-called "bud-blast." When the buds are not attacked until they are well developed, they turn brown and fail to open. The petals are then found to be a dark brown rotten mass, and this is known as the "bud-rot." In very wet seasons, as high as 80 to 90 per cent of the buds may be thus affected. Even the flowers may be discolored by spots resulting from this fungus. The leaves are usually the last to be attacked, and the symptoms are large irregular spots which become brown and dry.

While control methods have not been devised against this and other peony diseases, it is probable that sanitary measures will prove to be most practicable. The prompt and thorough removal of the wilted stems and rotted buds, together with the complete destruction by fire of all leaves and stems in the fall, will tend to lessen the extent of diseases the following year. For an

account of peony diseases by a specialist, see Whetzel "American Florist," April 10, 1915.

A. Fls. yellow or orange.

1. *lutea*, Franch. (*P. Delavayi* var. *lutea*, Finet & Gagnep.). St. woody, short, the plant glabrous: lvs. ternately parted, coriaceous, strongly nerved, glaucous beneath, the segms. obovate-oblong and cut or more

2721. Single peony. (× $\frac{1}{3}$)

or less lobed above the middle: fls. 2-4 in. across, terminal, golden yellow; outer sepals leaflike and long, the inner ones orbicular and yellowish green; petals 6-10, orbicular, concave, the outer ones irregularly crenate; filaments short, the golden yellow anthers long-linear: carpels 3, turgid, glabrous, the style short and recurved. China. B.M. 7788. Gn. 61, p. 267 (note); 76, p. 416. F.S.R. 1:230. R.H. 1906:14.

Var. *supérba*, Lemoine. Seedling from *P. lutea*, with larger fls. (3-4 in. across) and with carmine base to petals when the plant attains age: lvs. bronze-red during development, but becoming deep green. G.C. III. 44: suppl. July 18 (1908).

2. *Mlokosewitschii*, Lomak. Herbaceous perennial, the sts. stout and glabrous: lvs. 2-ternate, the lfts. or segms. broad-oblong or nearly elliptic, short-pointed or acuminate, 3-4 in. long, dark bluish green above and short-pubescent, pale glaucous beneath, the nerves and margins red: fls. 4-5 in. across, yellow, on glabrous reddish pedicels 4 in. long; sepals unlike, one of them oblong-lanceolate and constricted above the base and the other nearly orbicular; petals about 8, roundish,

concave; stamens very numerous, the filaments twice as long as anthers: carpels 3, oblong, whitish tomentose, the stigmas subsessile and purple. Caucasus; discovered by Mlokošewitsch and only recently intro.; said to be the most handsome of the yellow-fl. species. B.M. 8173. G.C. III. 44, suppl. July 25 (1908). R.H. 1911, pp. 432, 433.

3. *Wittmanniana*, Stev. Herbaceous perennial, 2-3 ft., green, glabrous and smooth: lvs. 4-8 in. long, 2-ternate; lfts. variable, usually ovate to ovate-cordate and the lateral ones often oblique at base, glabrous above, rather glaucous and lax-hairy beneath: fls. 4 in. across, solitary, pale or whitish, yellow or greenish; sepals irregular, green, concave; petals about 7, broad-elliptic-ovate, membranaceous, concave; stamens with orange-yellow anthers and slender red filaments: carpels 2 or 3, oblong-ovoid, glabrous, the stigmas recurved. Caucasus region. B.M. 6645. B.R. 32:9. R.H. 1906, pp. 348, 349. G. 27:135.—The first intro. of the yellow peonies, although not strongly yellow; intro. to gardens of

2722. *Paeonia albiflora*.

Royal Hort. Society (England) in 1842. Light and not pronounced in color, and apparently not of great promise.

AA. Fls. white, in shades of red or purple (exceptions sometimes in No. 11).

B. Petals scarcely longer than the sepals.

4. *Bröwnii*, Douglas (*P. californica*, Torr. & Gray). Low and somewhat fleshy, about 1 ft.: lvs. glaucous or pale, lobes obovate to nearly linear: fls. dull brownish red; petals 5 or 6, thickish, little if any longer than the concave sepals; outer sepals often leaflike and compound; fl.-sts. reclining or recurved; disk many-lobed: follicles 4-5, nearly straight, glabrous, the fr. finally resting on the ground from the bending over of the st.; seeds oblong. Early spring or summer. Calif. to Wash. and northward, and in Nev. and Utah. B.R. 25:30.

BB. Petals much exceeding the sepals.

C. Disk expanded and involving or enveloping the carpels: plants woody.

5. *suffruticosa*, Andr. (*P. Moutan*, Sims. *P. arborea*, Donn). TREE PEONY. St. 3-6 ft. or even higher much branched, distinctly shrubby: lvs. glabrous; lfts. more often entire at the base of the plant than above: fls.

large, various in color, as rose, red, to white: follicles numerous, very hairy, rather small. May, June. N. W. China.—Long cult. in the Orient, where varieties are numbered by the hundreds. The following varietal names have been transferred from combination with *P. Moutan*, now making new combinations: Var. *rùbro-plèna*, Bailey. Rose-colored, almost single. Var. *ròseo-superba*, Bailey. Fls. much more doubled. Gn. 31:76 (as *Reine Elizabeth*). F.S. 14:1395, 1396 (as *Triomphe de Grand*). Var. *vittata*, Bailey. Fls. single white, rose and flesh-color, striped, fragrant. F.S. 7:747. Var. *papa-veràcea*, Bailey. Petals thin and poppy-like, white, with red at center of fl. B.M. 2175. L.B.C. 6:547. Gn. 38:370; 52:325, and pp. 324, 325. Var. *Bánskii*, Bailey. Fls. much doubled, rose-colored, and large. B.M. 1154. Var. *Hùmei*, Bailey. Fls. semi-double, whitish or bluish with darker center. B.R. 379. Var. *ròsea*, Bailey. Fls. bright rose-colored, fragrant, more or less double. L.B.C. 11:1035.

6. *Delavayi*, Franch. Woody or subshrubby, branching, glabrous, 3 ft., more or less stoloniferous: lvs. ternate, somewhat glaucous beneath, 1 ft. long; segms. lanceolate or ovate-lanceolate, 2-4 in. long, cuneate, decurrent and confluent at base: fls. small (about 2 in. across), dark purple or velvety crimson; petals sub-orbicular, 5-9, remarkable for their firm substance; stamens yellow: carpels 5, glabrous, spreading. July. China, at high altitudes. Var. *angustifolia*, Rehd. & Wils., has more finely divided lvs., the lfts. being narrow-lanceolate. G.C. III. 53:403 (as *P. Delavayi*).—In Ireland *P. Delavayi* is said to be cut to the ground sometimes by the winter but it throws up new shoots in spring. Somewhat like *P. lutea* except in color of fls.

CC. Disk little if at all expanded and not enveloping base of carpels: plants herbaceous.

D. Blooms several on one st.

7. *Veitchii*, Lynch. Herbaceous, 2 ft., with 6 or 7 lvs. on st.: lvs. shining, light green, with many (about 15) very acute lance-oblong segms. which are about ½ in. broad; petiole of lowest lf. about 4-8 in. long: fls. several on the st. rather than solitary, nearly 4 in. across, often nodding and sometimes becoming flat, purplish crimson. W. China. G.C. III. 46:2. Gn. 73, p. 539. R.H. 1914, pp. 196, 197.—A recently described species; a compact, attractive plant.

DD. Blooms mostly solitary or single on each st. (partial exception in No. 8 and others under cult.).

E. Lfts. all entire, sometimes confluent at base.

8. *albiflora*, Pallas (*P. edulis*, Salisb.). Fig. 2722. Root of fusiform parts or tubers: st. 2-3 ft., often branching and bearing from 2-5 fls.: lower lvs. biter-nate; parts petiolulate or the lateral ones sessile, the lfts. (secondary lfts.) 3-4 in. long, oblong, lanceolate or elliptic, veining red: peduncle long, often with a large entire or lobed bract; outer sepals large, leaflike; petals large, various in color, usually white or pink, 8 or more; stamens golden yellow: follicles 3-5, ovoid, recurved-spreading, with spiral or reflexed stigmas. June. Siberia, China, Japan. B.M. 1756. F.S. 8:812. Gn. 30:588 (var. *Adrian*); 50, p. 170; 51:448. J.H. III. 58:493. Gt. 7:362 (forms). A.G. 23:643; 25:203.

Var. *Reevesiana*, Loud. (*P. Reevesii*, Hort.). A double form, with deep red petals. P.M. 1:197.

Var. *sinensis*, Steud. (*P. chinensis*, Vilm.). A tall Chinese variety, with large, double, crimson fls. One of the commonest forms in gardens. B.M. 1768.

Var. *festiva*, Planch. Fls. double, white, with a few marks of carmine in the center. F.S. 8:790-91.

Var. *Whitleyi*, Hort. (not var. *Whitleyi*, Anders., which has double pinkish fls.). Fls. single, large, white. Gn. 36:8; 63, p. 352.

9. *obovata*, Maxim. (*P. oreogeton*, S. Moore). Root or rhizome of elongated cylindrical tubers: st. 2 ft. high:

lower lvs. twice ternate; lfts. membranaceous, broadly ovate or obovate, more or less pubescent, especially beneath, the central one stalked: fls. not fragrant, 4-5 in. across, white according to G.C. III. 57:290 (usually described as red-purple); petals about 6, obovate, concave, very obtuse; sepals white or pale rose: carpels recurved, the seeds blue-black and berry-like. June. Siberia, N. China, Japan.

10. *coriacea*, Boiss. Allied to *P. albiflora*: glabrous, the st. nearly simple and reddish: lvs. coriaceous, glaucous beneath, the lower ones biternate; lfts. very broad: fls. bright crimson: carpels 2-3, deflexed, glabrous; seeds dark purple. June. Spain, N. Afr.

11. *corállina*, Retz. Tall, from carrot-form roots: lower lvs. biternate or rarely triternate; lfts. ovate or obovate, glabrous, or pubescent beneath: fls. purple or rarely whitish or even yellowish: carpels about 5, spreading or recurved, densely tomentose when young but glabrous at maturity; seeds round, reddish to dark blue and becoming black. April, May. S. Eu.

12. *Cambessedèsii*, Willk. Like *P. corállina*, but that species has glaucous-green never purple lvs. and hairy carpels: herbaceous perennial, about 1½ ft., simple, erect and glabrous: lvs. ternately pinnatisect, with ovate-lanceolate or oblong acute entire glabrous segms. that are deep green above and purple beneath: fls. deep rose-pink, solitary, erect, 3½ in. across, the petals 5-10, broadly obovate and crenulate; stamens many, with purple filaments and yellow anthers: carpels 5-7, erect, glabrous and shining, purple. Balearic Isls., Corsica. B.M. 8161.

EE. Lfts. more or less lobed.

F. Lvs. and st. glabrous throughout.

13. *tenuifolia*, Linn. Fig. 2723. Root or rhizome creeping, tuberous: st. 1-1½ ft. high, 1-flid., densely leafy up to the fl.: lvs. ternate, glabrous, cut into numerous segms. often less than 1 line broad: fl. erect; petals dark crimson, elliptic-cuneate, 1-1½ in. long; anthers shorter than the filaments; stigma red, spirally recurved: follicles 2-3, about ½ in. long. June. Caucasus region. B.M. 926. A.G. 17:658. Var. *flòre-plèno*, Hort. (Fig. 2723). Fls. double, crimson. F.S. 4:308. Var. *hýbrida*, Hort. Fls. of a rich crimson color: lvs. very pretty.

14. *anómala*, Linn. Root tuberous: st. 2-3 ft., 1-flid., glabrous: lvs. biternate, glabrous beneath, cut into numerous, confluent lanceolate long-acute segms.: fl. bright crimson, very large; outer sepals often produced into compound leafy points; petals obovate to oblong: follicles 3-5, ovoid, arcuate, tomentose or glabrous. June, July. Eu. and Asia. B.M. 1754. Gn. 67, p. 375.

Var. *insígnis*, Lynch. The variety most cult.: st. 1½-2 ft. high: lvs. about 10, the lower ones very large, gradually reducing to the fl.: carpels with red pubescence.

Var. *intermèdia*, C. A. Mey. Lvs. deeply lobed: fls. rosy crimson.

2723. *Paeonia tenuifolia*. (×½)

15. *officinàlis*, Linn. (*P. fulgida*, Sabine). Fig. 2724. St. stout, 2-3 ft. high, 1-headed: lvs. dark above, pale beneath, the lowest more divided than the others, having 15-20 oblong-lanceolate lfts., 1 in. or more broad: outer sepals leaflike; petals dark crimson, 1½-2 in. broad, obovate; stigmas crimson, recurved: follicles 2-3, becoming 1 in. long. May, June. Eu. One of the old forms in gardens. B.M. 1784. Gn. 53, p. 233.—By some combined with *P. peregrina*.

Var. *álbo-plèna*, Hort. Fls. double, white tinged with red. Gn. 19:14. Garden forms are given trade names, as: *anemonæflora*, crimson, globular fls., with a mass of twisted crimson stamens, edged with yellow. A.G. 17:663. Gn. 31:512; *blánda*, pale pink; *lobàto* lvs. distinctly lobed: fls. cerise-salmon, a very unusual color. Gn. 79, p. 351; *ròsea*, rich deep rose; *Sàbini*, rich deep crimson petals and yellow stamens. L.B.C. 11:1075.

Var. *festiva*, Tausch. Fls. white, with red centers. Native of Eu.

FF. Lvs. and st. pubescent, at least in the upper part.

16. *peregrina*, Mill. Sts. about 1½-2 ft. high: lvs. 5-6 on a st., deep green and glabrous above, pale green and pilose beneath; otherwise the lvs. and fls. are much like those of *P. officinalis*. Eu.—Two garden forms with double fls. are: *amaranthescens sphèrica*, and *pulchèrrima plèna*, the latter differing from the former in the purple shade of crimson fls. This species-name is used by Huth to cover a number of

2724. *Paeonia officinalis*. (×½)

the forms that by others are regarded as tenable species.

17. *paradóxa*, G. Anders. Plant one of the dwarfiest: lvs. in a dense tuft; lfts. 3-lobed and incised: fls. purple-red: carpels pressed closely together. S. Eu.—Differs from *P. peregrina* by smaller ovate and more glaucous lvs., lfts. more divided and crowded. Var. *fimbriàta*, Hort. Double purple fls., with projecting purple stamens; very pretty, but not much cult. in Amer. The species is sometimes referred to *P. peregrina*.

18. *arietina*, G. Anders. St. 2-3 ft. high, hairy toward the top: lvs. 5-6 on a st., rather glaucous and pubescent beneath; segms. oblong to oblong-lanceolate, strongly confluent, decurrent: fls. always solitary, dark red, large: follicles 3-4, densely tomentose, ovoid, spreading widely, becoming 1 in. long, strongly arched; stigma recurved. S. Eu. B.R. 819 (as *P. cretica*).—There are a number of horticultural varieties, under vernacular names. *Andersonii*, bright rose; *Báxleri*, crimson; *cretica*, bluish-pink. The species is by some combined with *P. peregrina*.

19. *decòra*, G. Anders. Tubers oblong: sts. 2-3 ft. high: lvs. horizontal, diminishing to the top; lfts. oblong-obtuse: fls. rather small, deep purple; petals few, small, narrow, peduncle long: follicles hairy, large, spreading from the base when mature. S. Eu. Var. *álba*, Hort., has satiny white fls., slightly tinted pink. Gn. 72, p. 291.

Var. *Pállasii*, G. Anders. Lvs. narrow-oblong: fls. rich crimson. G. 29:225.

Var. *elätior*, G. Anders. Lvs. broadly oblong: fls. rich crimson, very large: receptacle with few processes, and a connection between the carpels at their base of similar surface and appearance to that of the carpels.

P. Bräteri, Boiss. & Reut. (*P. corallina* var. *Bräteri*, Huth). Fls. red, varying to white: carpels densely white-tomentose: allied to *P. officinalis* and *P. corallina* in lvs. and habit.—*P. còrsica*, Sieber. Much like *P. coriacea*.—*P. Emòdi*, Wall. Closely related to and sometimes regarded as a synonym of *P. anomala*. B.M. 5719. Gn. 45:70.—*P. humilis*, Retz. (*P. peregrina* var. *humilis*, Huth). Rather low: fls. bright red: carpels glabrous or very nearly so. B.M. 1422.—*P. microcarpa*, Boiss. & Reut. Allied to the preceding and referred to it by Huth, but dwarfier. Var. *Jonathan Gibson* is a garden form, with very downy lvs.—*P. mollis*, G. Anders. Low, about 1 ft., with 1 fl. to the st.: lvs. dull green above, glaucous and pubescent beneath, with many oblong-lanceolate segms.: fls. deep red and subsessile: carpels 2-3, pilose, erect-curved. A doubtful species allied to *P. anomala*. L.B.C. 13:1263.—*P. pùbens*, Sims. Allied to *P. officinalis* probably: lvs. hairy below, margins red.—*P. Rússii*, Biv. (*P. corallina* var. *Rússii*, Huth). Allied to *P. corallina*, but with the lvs. decidedly hairy below.—*P. sessiliflora*, Sims. Nearly related to *P. mollis*; very low: fls. subsessile, white.—*P. trienàda*, Pallas (*P. corallina* var. *Pallasii*, Huth). Differs from *P. corallina* in its rounded lvs., green st., and rose or whitish fls. B.M. 1441 (*P. daurica*).

K. C. DAVIS.
L. H. B.†

PAINTED CUP: *Castilleja*.

PAINTED LEAF: *Euphorbia heterophylla*.

PALAFÓXIA HOOKERIÀNA: *Polyopteris*.

PALAQIUM: *Isonandra*.

PALAÛA (after Anton Palau y Verdera, professor of botany at Madrid the latter half of the eighteenth century). Also written *Palawa*, under which name it appears in lists. *Malvaceæ*. Flower-garden herbs.

Annual or perennial, tomentose or somewhat glabrous: lvs. usually lobed, dissected or sinuate: bractlets 0: fls. purple or purplish, axillary, peduncled, solitary; calyx 5-cut; stamens in a column which is much divided at the top; ovary many-celled; style stigmatose at the apex: carpels crowded without order.—Species 9 in 1908, as accepted by Ulbricht in Engler's Jahrb. 42; Peru and Chile.

dissècta, Benth. (*P. flexuosa*, Mast.). Slender annual, branched from roots: sts. 8-12 in. long, ascending, flexuous above: lf-stalks 1-2 in. long; blades 1-2 in. long and broad, triangular in outline, pinnatifid, the segms. lobed; lobes obtuse: fls. many, well separated from the foliage, about 1 in. across, lilac with whitish center, the stamens rose-purple and arranged in 5 longitudinal series; styles 25-30. Peru. B.M. 5768. H.F. II. 12:43.

L. H. B.

PALÀVA: *Palaua*.

PALISÒTA (named in honor of A. M. F. J. Palisot de Beauvois, 1752-1820, French administrator, traveler and botanist). *Commelinaceæ*. Perennial herbs, sometimes grown as pot or tub specimens under glass, as in palm houses, for the foliage.

Stem or caudex either long or very short, simple or nearly so, with the lvs. crowded at the top or base: lvs. long, parallel-veined, hairy when young and the margins with reddish or grayish hairs: fls. mostly white or purplish or rose, in many small cymes which are arranged in a dense or elongated panicle on mostly 1 peduncle that is terminal or essentially so; sepals and petals 3, the latter obovate; stamens 3, perfect, and 2 or 3 bearded staminodes; ovary 3-celled, with 1-several ovules in each: fr. a colored fleshy or succulent indehiscent berry.—Species about 15, in Trop. Afr. Little known in cult. outside of collections. The lvs. are often banded or striped, and the colored hairs make them conspicuous. For cult., see *Commelina*, p. 835.

P. Àlbertii, Gentil. Sub-caulescent: much like *P. Elizabethæ*, but lvs. not variegated and petioles without marginal hairs, also stronger-growing: lvs. very dark green, grayish hairy beneath, to 3 ft. long and 4-10 in. wide, long-attenuate to petiole, the latter widely channeled. Habitat not given.—*P. Bàrtéri*, Hook. f. Sts. 1-5 in. long, with lvs. near the base (i. e., practically radical), the young parts shaggy hairy: lvs. to 2 ft. long by about 4 in. wide, obovate-lanceolate, abruptly contracted into a tip 1 in. long, at

maturity with densely hairy margins but otherwise often nearly glabrous: infl. about 2 in. long (or longer in cult.), very many-fld.; fls. pale purplish. Upper Guinea. B.M. 5318.—*P. bicolor*, Mast., imperfectly known, has oblong-obovate lvs. about 1 ft. long, with a broad band in center of greenish yellow, the margins brown-hairy and fleshy petiole with broad purplish band. Upper Guinea.—*P. Elizabethæ*, Gentil (*P. Pynaertii* var. *Elizabethæ*, Hort.). Caulescent: lvs. long-acuminate, obovate-lanceolate, marked with greenish yellow variegation along the median line, 2-3 ft. long and 4-10 in. wide, long-attenuate to petiole, the latter thick and several inches long, broadly canaliculate with rufescent hairs on the margin. Habitat not given. G.C. III. 48:423. Gt. 64, p. 49.—*P. Pynaertii*, Wildem. The plant in cult. seems to be the variegated-lvd. form and which is probably the same as *P. Elizabethæ*, although the latter is said to differ in general form of growth and to have longer lvs. and with widely channeled petiole. Trop. Afr. R.B. 35:376 (as fol. var.).—*P. Schueinfurthii*, Clarke. St. 3-7 in. long and ½ in. diam., with 2 or 3 lvs. at the nodes: lvs. to 2 ft. or somewhat more and 8 in. broad, elliptic, short-acuminate at either end, densely hairy on margin but more or less glabrate otherwise: infl. 4-7 in. long, cylindric and very dense, containing several hundred fls. Trop. Afr., widely spread. G.W. 8, p. 553.—*P. thyrsoflora*, Benth. Shaggy-hairy on young parts, the sts. to 15 ft. long: lvs. very large, lance-obovate or oblong-elliptic, the margins densely hairy: fls. white, in a loose panicle often 2 in. wide and 10 in. long; ovary glabrous: berry ½ in. or more diam., blue. Upper and Lower Guinea. The *Dichorisandra thysiana*, Hort. (G.C. III. 28:302. R.B. 28:133), is probably this plant. It is described as a "plant of striking habit, and bold ascending foliage:" from Hort. Linden.

L. H. B.

PALIÛRUS (ancient Greek name). *Rhamnaceæ*. Ornamental woody plants sometimes grown for their attractive foliage and curiously shaped fruits.

Trees or shrubs: stipules usually changed into spines: lvs. alternate, 3-nerved, entire or serrate: fls. small, perfect, in axillary or sometimes terminal cymes; petals 5, 2-lobed; stamens 5: fr. woody, 3-celled, depressed subglobose, with a broad orbicular horizontal wing; cells 1-seeded.—Six species from S. Eu. to Tonkin, China, and Japan.

These are spiny trees or shrubs sometimes procumbent with two-ranked generally ovate medium-sized leaves and small greenish yellow flowers in axillary clusters followed by orbicular broadly winged, curiously shaped fruits resembling a head with a broad-brimmed hat. The one species cultivated in this country is not reliably hardy north of Washington, D. C.; in Massachusetts it is killed every winter almost to the ground even with protection, and the young shoots flower but bear no fruit. It is not very ornamental, but the dark green foliage is pretty and the curious fruits are interesting. It thrives in any well-drained soil and prefers a sunny and warm position. Propagation is by seeds stratified or sown in autumn and by layers or root-cuttings.

Spina-Christi, Mill. (*P. australis*, Gaertn. *P. aculeatus*, Lam. *Zizyphus Paliurus*, Willd. *Rhamnus Paliurus*, Linn.). JERUSALEM THORN. CHRIST'S THORN. Spreading, spiny shrub or small tree to 20 ft., sometimes procumbent: branches brown: 1 of the 2 spines at the base of the petioles straight, the other hooked and recurved: lvs. rather slender-petioled, ovate, usually unequal at the rounded base, obtuse, minutely serrulate, glabrous, dark green above, pale or grayish beneath, ¾-1 ½ in. long: fls. in axillary short-peduncled cymes: fr. brownish yellow, about ¾-1 in. across, glabrous. June, July. S. Eu. to Himalayas and N. China. B.M. 1893; 2535 (as *P. virgatus*). G.C. III. 50:377.—This plant is supposed to have furnished the crown of thorns which was placed on the head of Christ before his crucifixion; others think *Zizyphus Spina-Christi* to be the shrub the crown was made of. These two shrubs resemble each other closely, but the branches are whitish and the frs. berry-like in *Zizyphus*; the shape of the spines is exactly the same in both species.

P. orientalis, Hemsl. Tree, to 30 ft.: sometimes unarmed: lvs. 2-4 in. long, glabrous: fr. 1-1 ½ in. across, glabrous, purplish. China. This but recently intro. species is perhaps the most ornamental of the genus; it has not proved hardy at the Arnold Arboretum.—*P. ramosissimus*, Poir. (*P. Aubletii*, Rom. & Schult.). Shrub similar to *P. Spina-Christi*, but with both spines straight, with larger lvs. pubescent beneath, and smaller tomentose fr. with narrow wing. China, Japan.

ALFRED REHDER.

PALM. Palms are amongst the most striking plants in tropical floras. The tall mostly straight unbranched trunks surmounted by a spreading canopy of huge pinnate or digitate leaves distinguish them from nearly all other forms of vegetation. They are widely spread in warm regions, being most abundant in America and Asia and few in Africa. They are particularly conspicuous in the Pacific Islands. Although the palms are such bold and interesting plants, the species are imperfectly understood. This is due to the great difficulty of making herbarium specimens, to the fact that the greater number of botanists are residents of regions in which palms do not grow, and to the differences of opinion as to the relative importance of the various botanical characters. Many of the palms have been named first from cultivated specimens, and often before the flowers and fruits are known. When the specimens finally come to fruit, the names are usually shifted, causing much confusion. The proper generic position of a palm may be unknown for several years after it becomes popular in the horticultural trade. Consider the changes in nomenclature which have occurred in palms that have been referred to the genera *Areca* and *Kentia*.

The species of palms are not very numerous as compared with orchids, composites and grasses. They probably do not greatly exceed 1,200, as at present known, although more than that number have been described. Bentham & Hooker accept 132 genera, and Drude, in Engler & Prantl's "Pflanzenfamilien," accept 128 genera. Most of the genera are small, and many of them are monotypic. The largest genera are *Calamus*, with about 200 species, all Old World, mostly Asian; *Geonoma*, with about 100 species, all American; *Bactris*, about 100, American; *Chamædorea*, with about 60, all American; *Licuala*, with 30, ranging from eastern Asia to Australia; *Desmoncus*, about 25, American; *Cocos*, 30, all confined to America but the coconut, which is now cosmopolitan; *Pinanga*, with about 25 species, of the oriental tropics; *Areca*, nearly two dozen, oriental. Many of the species, particularly in the small genera, are restricted to very small geographical regions, often to one island or to a group of islands. The palms represent an old type of vegetation, and they are now, probably, on the decline, as measured

General characteristics.

The members of this family are essentially tropical in habitat, are highly ornamental in appearance, and many of them also of very great economic value, their fruits, stems and leaves not only entering largely into the manufactured products of both Europe and America

2726. Flowers and fruit of *Thrinax Wendlandiana*.—a, top part of flowering branchlet; b, flower; c, fruiting perianth, seen from above, from which the fruit has been taken; d, fruit; e, longitudinal section of seed, through embryo.

but also providing both food and shelter for thousands of the inhabitants of tropical countries. One notable characteristic of palms in general is their unbranched stems, the exceptions to this rule being very few and mostly limited to the members of one genus, *Hyphæne*, of which the doum palm of Egypt, *H. thebaïca*, is the best example. While these unbranched stems form a prominent feature in connection with this order of plants, yet great variations are found in size and habit, some of them towering up like a slender marble shaft to a height of more than 100 feet and then terminating in a crown of magnificent plume-like leaves, while others may reach a height of only 3 to 4 feet when fully developed, and some species are permanently stemless. In some examples the stems are so long and slender that a scandent habit is the result; these rope-like stems of the rattan palms in particular are described as wandering through the tops of some of the great trees of the Malayan Peninsula to a length of several hundred feet, —reported as long as 1,700 feet, but report unreliable.

The foliage of the palms is of two chief kinds, the fan-veined leaves, in which the venation radiates from a common center, and the feather-veined, in which the veins run out from the sides of a long midrib, the leaf being frequently divided into long narrow segments. Of the first group, the common fan palm, *Livistona chinensis*, is a good example, while the date palm, *Phoenix dactylifera*, and also the coconut, *Cocos nucifera*, are common examples of the feather-veined class. There are also minor characteristics of foliage that mark many of the genera, some having pinnate leaves with erose tips, a few having bipinnate leaves (as *Caryota urens*), others with flabellate leaves having erose segments, and many with the segments of the leaves bifid or split at the tips.

The flowers of palms in general are not specially attractive either in size or coloring, many of them being greenish white or yellow, and some orange or red; but these flowers are produced in prodigious quantities by some of the species, perhaps the most prolific in this respect being the talipot palm (*Corypha umbraculifera*), which throws up a branching inflorescence to a height of 30 feet above the foliage, such an inflorescence having been estimated to include fully 60,000,000 flowers! This, of course, applies only to wild specimens.

The seeds of palms are also found in many sizes and various shapes, ranging from the size of a pea in some of the *Thrinax* to the unwieldy fruit of the double coco-

2725. Flower and fruit of *Pritchardia Wrightii*.—a, flower in anthesis, with one segment remaining attached to corolla-tube; b, flower in lengthwise section, segments and anthers wanting; c, anther, dorsal view; d, anther, ventral view; e, lengthwise section of carpel; f, young fruit, with remains of sterile carpel at apex; g, section of kernel, showing entire seed inside; h, section of seed along line of raphe.

in geological epochs.—Perhaps the most complete account of the botany of certain groups of palms is by O. Beccari in such works as: "The species of *Calamus*," "Le Palme Americane della tribu della *Corypheæ*," "Notes on Philippine Palms," and many smaller papers. O. F. Cook has also written extensively of the American species.

nut, *Lodoicea maldivica*, which will sometimes weigh forty pounds each and require several years to reach maturity.

As a rule, the members of any single genus of palms are found in one hemisphere, either the eastern or western as the case may be, probably the greater num-

2727. Flowers and fruits of *Acclorhaphie Wrightii*.—a, part of flowering branchlet; b, unopened flower; c, flower full open; d, fruit; e, kernel of fruit; f, seed as shown on the raphal side; g, lengthwise section through embryo.

ber of species being of Asiatic and American origin, rather than African. An apparent exception is found to this system of hemispheric distribution in the case of the coconut, this plant being so very widely distributed throughout the tropical world that its original habitat is still in doubt. On the other hand, some species are known to be very local in their natural state, in proof of which the howeas may be cited; this genus has been found only within the circumscribed area of Lord Howe's Island, which, from a comparative point of view, may be termed merely a fragment of land (probably of volcanic origin), a mere dot on the broad bosom of the South Pacific.

Few palms are found within the limits of the United States as natives, the most common being the well-known palmetto, *Sabal Palmetto*, a member of the fan-leaved section, to which many of the American palms belong. But while the species of palms native in the United States are limited in numbers, yet there is at least one unique species in the group in the form of *Pseudophoenix Sargentii*, a monotypic palm, that is known to exist in a wild state only on certain of the Florida Keys, and in limited numbers even there, and recently in Cuba and Santo Domingo.

Europe is even less favored as to native palms, there being but one species known there in that condition, *Chamærops humilis*, also a fan-leaved species and comparatively hardy, being capable of enduring moderate frosts.

The palm tree of the Bible is doubtless the date palm, *Phoenix dactylifera*, which is found in large numbers throughout Syria to this day; and in fact the small grove of dates within easy reach of the Syrian householder forms one of his most valuable assets, for it provides food not only for his family, but frequently for his horses or camels also.

The act of producing flowers does not necessarily terminate the life of a palm, though in some instances such an effect may be produced by this cause; but a singular habit has been noted in regard to the flowering of the fish-tail palm, *Caryota urens*, which when it reaches maturity begins to throw out a flower-spike from the top of the stem, this being followed by successive spikes of flowers, and ultimate bunches of seeds from the top of the plant downward, the flower-spikes appearing at the joints of the stem, and when this process of flowering has proceeded down to the ground, or

until the vitality of the plant has been exhausted, death ensues.

There are also a number of species of palms that develop a soboliferous habit, throwing up a number of shoots from the base of the plant, *Rhapis flabelliformis*, sometimes known as the ground rattan, being a good example of this class, among which the widely grown and elegant *Chrysalidocarpus lutescens* is also found, together with the *geonomas*, some of the phoenix and various other genera. Many of the palms are unisexual, but there are also many others in which both male and female flowers are produced on the same spadix, in some examples the males being grouped together near the ends of the branches of the inflorescence and the females nearer to the main stem, while in others a female is placed between two males, thus arranging the flowers in threes.

Cross-pollination of palms by artificial means has probably been seldom practised, there being few cultivated collections in which the opportunity for such an operation has presented itself; but it seems highly probable that such cross-fertilization has been accidentally effected among wild plants, for in large lots of seedlings intermediate forms are frequently seen, this peculiarity having been noted among *howea* seedlings, where forms intermediate between *H. Belmoreana* and *H. Forsteriana* are found, and sometimes seedlings that seem to combine the characteristics of *H. Belmoreana* and those of its near relative *Hedyscepe Canterburyana*. Similar variations from a given type have also been noted among the phoenix, several so-called species being most likely merely varieties.

Many palms are armed with stout thorns or prickles, not only the stems but also the leaves and even the fruits in some species being thus guarded, these prickles being usually very hard and tough. In some cases, notably *Acanthorhiza aculeata*, the prickles around the stem are often branched, and are decidedly unpleasant to come in contact with. In the case of *Desmoncus*, this being the western representative of the rattan palms, the tip of the midrib of the leaf is continued in the form of a hooked spine, and helps to support the plant in its scandent career. The sharp spines of certain palms are used for poisoned arrows by some of the South American tribes, these arrows being projected through a blow-pipe formed from a section of the hollow stem of another palm. Among the species of *Phoenix*, it is often found that several of the leaflets nearest to the base of the leaf are developed as spines, these thorny leaflets becoming stiff and hard, and capable of making a very sore wound.

The very great economical value of many of the palms can only be touched upon within the limits of the present article, the uses to which not only the fruits but also the stems and leaves are put by the natives of many tropical countries being enough of themselves to fill volumes. One prominent example of this great utility is the *Palmyra* palm, of which a Hindoo poet enumerated over 800 different uses. Other notable examples include

2728. Flowers and fruit of *Coccothrinax Miraguano*.—a, part of flowering branchlet; b, flower from which ovary has been removed, inner view; c, flower viewed, from behind; d, seed, with hilum in center; e, seed, upper surface; f, seed in transverse section; g, lengthwise section of seed, through embryo.

the coconut palm, the fruits of which are imported by hundreds of tons every year, and in addition to providing a valuable food, either fresh or in a desiccated condition, also produce that very valuable fiber from which cordage, matting and a great variety of goods are manufactured; also the Phoenix family, which produces the dates of commerce in apparently endless supply, and the date sugar of Bengal, this being contributed by *Phoenix sylvestris*, while the stems of date palms are often used in house-building in the East. Another very valuable palm product is found in palm oil, this being largely derived from the fruits of *Elæis guineensis*, the oil being expressed from the ripe fruits in much the same manner that olive oil is manufactured. The rattan of commerce is chiefly composed of the flexible stems of various calami, the plentiful supply of this material being sufficiently attested by the great variety of articles manufactured therefrom. Various palms have been mentioned under the name of "wine palm," but it seems likely that some species of *Raphia* are most used for liquors, some portions of these palms giving a large amount of sap when tapped, and as the juice is rich in sugar, the sap soon ferments and

2729. Flowers and fruit of *Copernicia Curtissii*.—a, summit of flowering branch; b, single flower; c, flower in longitudinal section; d, fruit; e, seed, from the raphe side; f, seed, side view; g, seed in longitudinal section through embryo.

The attaleas also produce large seeds or nuts, those of *A. funifera* being known as coquilla-nuts, and very largely used for ornamental purposes, being very hard and capable of receiving a fine polish. Many small articles are manufactured from vegetable ivory, this being secured from the nuts of *Phytelephas macrocarpa*, a singular palm from South America, bearing a large fruit in which are contained from six to nine of the ivory-nuts, the plant itself having a short and sometimes creeping stem from which proceeds a noble head of pinnate fronds that are frequently 15 to 20 feet in length. The seeds of *Areca Catechu*, after preparation with lime and the leaves of the pepper-plant, become the betel-nut of the East Indies, so much used by the natives of that portion of the world as a mild stimulant. The cabbage palm of the West Indies is *Oreodoxa oleracea*, the smooth and straight stems of which are frequently 80 to 100 feet high, and the removal of the "cabbage," so-called, means the destruction of such a tree, for the portion eaten is composed of the central bud in which the young leaves are compactly gathered together.

Botanical structure.

As the trunk of the palm rises, the leaves underneath the crown die and fall. Usually the old petioles, or

their bases, remain for some time, forming a shaggy capital to the column; this is well marked in the large or cabbage palmetto of the South. The palms are mostly trees, and sometimes rise to the height of nearly 200 feet, but some are climbing and others are low shrubs. Some palms are only a foot or two tall at

2730. Flowers and fruit of *Hemithrinax compacta*.—a, part of flowering branchlet; b, c, flowers in anthesis; d, e, anthers, from dorsal side; f, anther from inner side; g, flower with anthers removed; h, lengthwise section of ovary; i, fruit; k, seed; l, lengthwise section of seed, showing embryo.

maturity, as *Malortiea*. In some species the stems are prickly. Usually they make very straight comely boles, but a few species produce branches above.

The inflorescence of palms usually arises underneath or in the crown, from the axils of the leaves. The clusters are really spadices, although often branched, and are covered in the bud by a dry spathe composed of one or several leaves or parts. The remains of these spathes are well shown in Fig. 2538 (page 2298). In the upper cluster on the left, the spathe is arching over the fruits. The blossoms are relatively small, and usually dull colored and not showy, but in some species the spadix is scarlet or yellow and often very gracefully branched. The spathes are sometimes immense woody coverings, like troughs or bowls.

The flowers of palms are not greatly differentiated or specialized. The essential structure may be understood by comparing the details in Figs. 2725 to 2731, which are adapted from Beccari's account of palms indigenous to Cuba in *Pomona College Journal of Economic Botany*, February, 1913. Of most palms, the flowers are small or minute, quite regular, and they may be either hermaphrodite, monoecious, or dioecious. Often the whole flower is nearly woody, even the perianth-parts being hard and scarcely resembling petals. In most species there are two series of perianth-parts: three distinct imbricated sepals inclosing three distinct or partially united petals. Many modifications of this arrangement are known, however, as in the case of cer-

2731. Flowers of *Copernicia glabrescens*.—a, summit of flowering branch; b, top view of open flower; c, flower, side view; d, flower in longitudinal section.

tain species of *Thrinax* where the perianth is reduced and deformed, and of *Nenga* where the sepals are longer than the petals. There are nearly always six stamens, both in the pistillate and staminate flowers, and except in certain species of *Oreodoxa* (*Roystonea*) they are always included. They are often in two series, one opposite the sepals, the other opposite the petals, always free, and nearly always inserted on the short perianth-tube. The anthers are linear, oblong or arrow-shaped, two-celled, the pollen usually ellipsoid or nearly round, very rarely minutely spiny. The ovary is free, ovoid or oblong or globose, and often found in a rudimentary form even in staminate flowers, but sometimes lacking in the latter. There are mostly three cells, but four and even up to seven cells are known in rare cases. The ovule in each cell is solitary and almost always erect.

Great variety characterizes palm fruits. Some are dry and hard almost stone-like fruits, others are fleshy and even drupe-like. In many species there is a hard fibrous coating to the fruit, as in the case of the coco-

2732. A palm-house.

nut. In other species the seed is free, but often it adheres to the inner coat of the fruit; it nearly always contains a copious albumen.

The individual flowers and fruits of palms are borne on a large inflorescence (spadix) which may or may not be inclosed in a sheath-like structure (spathe). The form and branching of this spadix varies much. One character that seems to hold is that of the branching, in one group of genera the spadix being either simple or imperfectly branched, if compound then paniculate, such as is found in *Geonoma*, *Euterpe*, and allied genera; and in others the spadix is always pinnately branched, the ultimate branches distichous if greater ramification is present.

Horticultural importance, and culture.

Palms have been favorite greenhouse subjects from the period of the first development of the glass plant-house. The stereotyped form of conservatory is a broad or nearly square structure, with narrow benches around the sides over the heating-pipes and a palm-bed in the center. In these conservatories a variety of palms will succeed, requiring neither a very high temperature nor much direct sunlight. (Fig. 2732.) In fact, palms usually succeed best under shaded roofs. The

palms are most satisfactory in their young state, before the trunks become very prominent, and before the crowns reach the glass. The larger number in houses have pinnate or pinnatisect leaves, and these species are usually the more graceful in habit, although the fan palms are also much prized. Small palms are now in great demand for room and table decoration, and a few species are grown in enormous quantities for this trade. They are sold when small. They usually perish before they are large enough to be cumbersome. Among the most popular of these palms are *Chrysalidocarpus lutescens*, *Howea Belmoreana* and *H. Forsteriana*, *Cocos Weddelliana*, *Livingstonia chinensis*, and possibly one or two species of *Phoenix*.

Some palms endure considerable frost without injury. Of such are the sabals and the palmettoes of the southern states. The saw palmetto (*Serenoa serrulata*) and the blue palmetto (*Rhapidophyllum Hystrix*) occur as far north as South Carolina. In Asia, Nannorhops occurs naturally as far north as 34° and grows in the mountains of Afghanistan where snow falls, and in Europe. *Chamærops* (the only palm indigenous to Europe) reaches 44°.

The genera chiefly known to horticulturists are the following:

TRIBE ARECEÆ. *Lvs. pinnatisect, the lfts. free or joined so as to form a plaited limb, the sides in veneration reduplicate: fls. monœcious or diœcious: seeds umbilicate, with ventral raphe and dorsal embryo.*

Areca, Pinanga, Kentia, Hydriastele, Kentiopsis, Hedyscepe, Nenga, Archontophoenix, Rhopalostylis, Dictyosperma, Ptychosperma, Cyrtostachys, Drymophloeus, Cyphophoenix, Clinostigma, Cyphosperma, Euterpe, Acanthophoenix, Oreodoxa, Acrista, Bacularia, Linospadix, Howea, Ceroxylon, Verschaffeltia, Dypsis, Chamædorea, Hyophorbe, Roscheria, Geonoma, Calypstrogyne, Bentinckia, Wallichia, Didymosperma, Arenga, Caryota, Phytelephas, Pseudophoenix, Elæocarpus.

TRIBE PHENICEÆ. *Lvs. pinnatisect, segms. acuminate and with induplicate sides in veneration: spadices interfoliar, the spathe solitary: fls. diœcious: carpels 3, only 1 maturing, the stigma terminal; seed strongly ventrally sulcate, the embryo usually dorsal.*

Phoenix.

TRIBE CORYPHEÆ. *Lvs. fan-shaped, wedge-shaped or orbicular, plaited, more or less cut, the lobes with induplicate sides: spadices interfoliar, the spathes many: fls. usually perfect; ovary entire or 3-lobed or sometimes the 1-3 carpels distinct, the ovule erect; pericarp usually smooth; seeds with ventral raphe and small hilum.*

Corypha, Sabal, Washingtonia, Chamærops, Rhapidophyllum, Acanthorhiza, Brahea, Erythea, Pritchardia, Licuala, Livistona, Trachycarpus, Rhaps, Thrinax, Nannorhops, Serenoa, Copernicia, Teysmannia, Trithrinax, Coccothrinax.

TRIBE LEPIDOCARYEÆ. *Lvs. pinnatisect or fan-shaped, the segms. with reduplicate sides in veneration: spadices terminal or axillary, the spathes numerous: fls. polygamo-monœcious; ovary entire, more or less 3-loculed: fr. clothed with reflexed, shining, imbricate, appressed scales; seed with dorsal raphe and ventral embryo.*

Calamus, Ceratolobus, Raphia.

TRIBE BORASSEÆ. *Lvs. orbicular, the segms. fan-shaped and the sides induplicate: spadices interfoliar, the spathes many and sheathing: fls. diœcious, the male minute and sunk in cavities on the spadix, the female very large, ovary entire, 3-loculed, the ovule ascending: fr. various.*

Borassus, Lodoicea, Latania, Hyphæne.

TRIBE COCOINEÆ. *Lvs. pinnatisect, the lfts. with reduplicate sides; spadices interfoliar, unisexual or androgynous, the spathe 2 or more; inferior fls. often in 3's, the middle one female; ovary 1-7-loculed: fr. large, drupe-like, 1-7-loculed, the stigma terminal, the endocarp or shell hard and woody and provided with 3-7 pores.*

Bactris, Astrocaryum, Acrocomia, Martinezia, Elæis, Diplothemium, Cocos, Maximiliana, Scheelea, Attalea, Jubæa, Desmoncus.

There is very little accessible monographic literature on the palms. Martius' "Historia Naturalis Palmarum," Munich, three volumes, 1823 to 1850, is a standard work. Kerchove de Denterghem's "Les Palmiers," Paris, 1878, is an important work. A popular running account of palms and the various kinds, by William Watson, will be found in the following places in *Gardeners' Chronicle*: 1884 (volume 22), pages 426, 522, 595, 728, 748; 1885 (volume 23), pages 338,

2733.

Germination of *Chrysalidocarpus lutescens*.

410, 439; 1885 (volume 24), pages 362, 394, 586, 748; 1886 (volume 25), pages 75, 139, 557; 1886 (volume 26) pages 491, 652; 1887 (volume 2, series 3) pages 156, 304; 1891 (volume 9), pages 234, 298, 671; 1893 (volume 13), pages 260, 332.

Palm-culture, for decorative purposes in the United States, has made its greatest progress within the past twenty-five years, and now seems to be a well-established business, with the prospect of a steady increase as the adaptability of these plants becomes better understood. A great area of glass is now in use for palm-culture alone, the middle states being the center of this industry, though large numbers are also grown in a few southern states; and owing to a favorable climate and gradually improving business methods, it seems probable that American growers will soon be able to compete with their more experienced brethren of Europe in this class of plants.

The species most used in commercial horticulture in the United States are contained in a very short list, the greater quantity being confined to five species, namely, *Livistona chinensis*, *Howea Belmoreana*, *Howea Forsteriana*, *Chrysalidocarpus lutescens*, and *Cocos Weddelliana*, while less quantities of *Caryota urens*, several species of *Phoenix*, *P. canariensis* being very largely planted outdoors in the South and on portions of the Pacific coast, *Seaforthia elegans* and some others of the *Ptychosperma* group, and some few *livistonas* cover the extent of the catalogue for many growers.

Of these, the seeds are imported in most cases, and on the quality of these seeds the success of the grower depends, so far as getting up a stock is concerned. Most of these species germinate readily in a warm greenhouse, providing the seeds are fresh, the slowest of the common commercial palms being the *howeas*. In small quantities these seeds are usually sown in about 6-inch pots, the pots being well drained

and nearly filled with light soil, then the seeds sown thickly and covered with $\frac{1}{2}$ inch of soil, watered thoroughly and placed where they may receive the benefit of some bottom heat; and at no time should they be allowed to become very dry. The period required for germination varies greatly with different species, *Livistona chinensis* germinating in two or three weeks if fresh, and being ready for potting in about two months, while seeds of some of the *attaleas* have been known to remain in the earth for fully three years before starting.

The seedlings of many species are very much alike, the seed-leaf in many instances being a long narrow simple leaflet, this description often applying equally to the seedlings of both fan-leaved and pinnate-leaved species; and from this fact it is somewhat difficult to recognize a species while in the juvenile form. Figs. 2733-2736 show stages in the germination of common palms. Special cultural notes for particular species of palms will be found throughout the *Cyclopedia*, but at this time a few general remarks regarding treatment of palms as a whole may be admissible. It has already been noted that palms in general are tropical in nature, and while there are a number of species that are found at considerable elevations, where the nights are decidedly cool, yet in a young state the same species may make more progress in a night temperature of 60° F.; and with this in view, a minimum temperature during the winter of 56° to 60° is safest for young and growing palms, while an advance of 15° to 20° during the day will not hurt them.

An abundance of water is required, for many palms grow on the banks of rivers or in swampy ground; and even those found on high and rocky ground send their roots down to such a depth as to find a liberal water-supply.

Rotted sod is the basis for the best soil for palms, and a fair proportion of stable manure is a safe fertilizer, such a soil being mixed with various proportions of peat or sand, to make it lighter and more open for some delicate species.

Insects are frequently troublesome if allowed to gain headway, various scale insects doing the greatest damage, while red-spiders and thrips may become established unless forcible syringing is persisted in. The most successful practice requires close observation on the part of the grower, and the prompt removal of all insects. Many other pests are also known and in the report of the Missouri Botanical Garden for 1898, Trelease gives an account of many of these. Busch in a report on investigation of diseases of the coconut palm in United States Department of Agriculture Bulletin of Entomology II. 38, 1902, gives an account of a disease that threatened the coconut industry in Trop. America.

Summer care of palms.

Some shading throughout the summer is best, the foliage grown under glass being more tender than that

2735. Germination of *Cocos Weddelliana*.2734. Germination of *Livistona*.

naturally produced outdoors. Repotting should be done during the spring and summer months, preferably, there being comparatively little root-action on the part of most palms between November 1 and March 1. Give only moderate-sized shifts, that is, use pots only 1 or 2 inches larger, and always ram the soil firmly.

Florists especially must understand the summer treatment of decorative palms. The usual weather of midsummer, which includes not only high temperature, but also fairly high humidity, is a help for the grower of palms, for such conditions do much to promote the growth of the stock, provided that watering, syringing, and proper attention to ventilation be given. A little ventilation at night, in addition to fairly liberal airing during the day, tends to prevent an over-accumulation of moisture on the foliage, and also has an influence toward the prevention of fungoid growths on or about the plants, for in houses so continually warm and moist as is the average palm-house, there is much encouragement for fungus on the woodwork of the benches and about the plants.

A sprinkling of slaked lime under the benches is also a help to the atmosphere and discourages snails to some extent, the latter pest being sometimes very troublesome, especially on the young growths of kentias. Two of the worst periods for the reproduction of scale insects are in the months of May and September, and if these pests can be kept down at those periods, there will be much less trouble in the remainder of the year.

Those who grow palms in quantity have to depend upon dips and spraying with various insecticides, from the fact that it is practically impossible to give the time to each plant that may be afforded by those who carry only a few dozens of palms in stock, but in either case most of the work of this character is likely to be done in the summer months, when there may be a little more time devoted to such work than can be spared in the busier seasons of spring and fall. This fact probably accounts for some of the insect tribulations to which the grower is exposed, as he is seldom able to find time to fight insects at the time of the spring rush, and by this means new colonies are distributed before the danger is appreciated.

Kentias and cocos are undoubtedly the palms for the million at this stage of the florists' art in America, and the necessities of these admirable plants are well understood. Seaforthias and ptychospermas were rather more common to the trade fifteen to twenty years ago than they are now, and were used for decorative work before the kentias absorbed so much attention. Instead of using seaforthias for decorating, persons are adding them to the outdoor garden in those parts of the South where palms add so greatly to the permanent effect in the outdoor planting.

The common *Phoenix canariensis* and other strong-growing members of that subfamily are also frequently in demand for outdoor use, while the dwarf date, *Phoenix Roebelenii*, continues to be in demand for house decoration, under which condition it is eminently satisfactory; it has found further usefulness even in small sizes, in being used to some extent for the centers of fern-pans. *Livistona rotundifolia* is one of the most charming of dwarf palms, but is easily spoiled by insects, requiring constant vigilance on that account, while a comparatively high temperature and moist atmosphere are also essential to its welfare.

W. H. TAPLIN.

N. TAYLOR.†

Palms in California.

Palms grown in the open in California gardens do not exceed about twenty-six genera, and numbering about eighty species. In this account may be found the species growing in the gardens of Los Angeles and vicinity, and throughout southern California in limited numbers from San Diego to Santa

Barbara. Occasional plants of species not mentioned are found in some old gardens, but are not so plentiful as to be considered in a general list of the hardy palms. A complete list of palms grown somewhere in southern California is given by Franceschi as follows: Archontophoenix, 2 species; Hedysepe, 1; Rhopalostylis, 2; Clinostigma, 1; Bacularia, 1; Howea, 2; Chamaedorea, 10; Gaussia, 1; Phoenix, 10; Sabal, 10; Washingtonia, 3; Chamaerops, 1; Rhipidophyllum, 1; Serenoa, 2; Brahea, 3; Erythea, 4; Pritchardia, 2; Livistona, 6; Trachycarpus, 2; Rhaps, 2; Thrinax, 2; Trithrinax, 2; Copernicia, 1; Acrocomia, 1; Cocos, 10; Jubæa, 1.

In enumerating the prevailing garden palms, they are placed as to their importance, or rather as to their numerical strength in California. The native fan-palms, the washingtonias, natives of San Bernardino and San Diego counties, have been most extensively planted, and may be found everywhere, serving, in some instances, a variety of purposes. (Fig. 2737.) In growing this palm, water is of the first importance. When planted along a street, those adjoining vacant lots often remain nearly at a standstill, except in case of an unusually wet winter, while those along the cultivated lots or lawns grow faster than any other palm. When one in its native habitat blows over by the force of the desert winds, the hole left by the roots and stump invariably fills with water. Washingtonias are hardy 600 miles north of Los Angeles. It may be well to state that hardiness in palms is principally a question of size, the larger ones passing through the most severe winter unharmed, while the small ones may perish. So, also, some palms supposed to be very tender need protection from sun more than from frost. This is particularly the case with the so-called kentias and rhaps. A certain howea (or *Kentia Forsteriana*) is protected only by a large overhanging branch of a sycamore, which is of course leafless in cold weather, yet it has reached a height of 12 feet, with a diameter at base of 12 inches, and it has never been injured by frost, yet water hydrants 10 feet away have been frozen so hard as to burst them. In Los Angeles is a kentia 15 feet high, growing on the north side of a house, protected from sun alone, being 20 feet from the building, where for several winters the ground nearby has frozen to the depth of 1 inch. This is in the bottom-lands, the coldest part of the city.

Phoenix dactylifera, although not so ornamental as others of the genus, was extensively planted in early

2736. Germination of
Howea Belmoreana.

days and is one of the hardiest of palms (Fig. 2738). The most popular palm for the masses, who look for grace and beauty combined with cheapness, is *Phoenix canariensis*. More of these are planted at present than of any other three species. In Los Angeles and

2737. A sentinel palm.—*Washingtonia filifera*, San Jacinto Mountains, California.

vicinity they may be counted by tens of thousands. Like these two for hardiness is *P. reclinata*; and all may be seen growing north of San Francisco some 200 miles. All the genus is hardy in southern California. *Trachycarpus excelsus* and *Chamærops humilis*, the latter varying greatly in appearance, will grow as far north as any palms and are popular everywhere. The former in thirty years will grow to the height of 25 feet, while the latter will make 8 to 10 feet of trunk in the same time. *Livistona australis* and *L. chinensis* are both popular, though not hardy outside the southern part of the state, and the latter must be shaded from noonday sun. *Erythea armata* and *E. edulis* (often known as braheas) grow around San Francisco Bay luxuriantly. The dwarf sections of *Cocos*, represented chiefly by the one known in the trade as *Cocos australis*, is hardy even farther north than the erytheas, and are by far the most ornamental palms to be found in that section. Other *cocos* in southern California are *C. flexuosa*, *C. plumosa*, *C. coronata*, *C. Romanzoffiana*, and many others. Any *cocos* will grow here in protected places except *C. Weddelliana*. Palms of the *Cocos flexuosa-plumosa-Romanzoffiana* type are the most graceful grown, and at present very extensively planted in the southern citrus belt, sometimes for street or sidewalk trees. It is also one of the fastest growers, and will reach 20 feet in fifteen years, with ordinary care. *Archontophoenix Alexandræ* and *A. Cunninghamii*, the most elegant of our palms after the *Cocos plumosa* type, are not quite so hardy but will thrive from Santa Barbara southward, in warm locations. The same exposures, with shade during the hottest part of the day, will do for *Hedyscepe Canterburyana* and *Howea Forsteriana* and *H. Belmoreana*; also *Rhopalostylis Baueri* and *R. sapida*. The

four species of sabals seem to thrive and seed well in this section, though *S. Palmetto* and *S. Blackburnianum* grow much faster than the others. *Rhapidophyllum Hystrix* is perfectly hardy, but on account of its dwarf habit is not so extensively planted as its merits deserve. *Rhapis flabelliformis* and *R. humilis* need protection from sun alone, though there is a *rhapis* growing for ten years without protection from either sun or frost, and in the coldest section of Los Angeles, but its color is not all that could be desired. *Chamædoreas* are planted only where they can be protected from both frost and sun, though they thrive better under such circumstances than they do under glass. In such situations they are just the plant for the purpose, as they do not grow away from the protecting tree as do sun- and light-loving palms, but remain erect. *Brahea dulcis* may occasionally be seen, but grows too slowly to be popular. One of the grandest and hardiest palms, one that deserves for many reasons to be more extensively planted, is *Jubæa spectabilis*. There are a few specimens 20 feet in height with a bole 4 feet in diameter.

List of California palms. (Wright.)

The following list of palms for southern California has been compiled from many years of observation by J. Harrison Wright. While not entirely complete as regards the newest and untried introductions, it covers all the hardier species and it is made with special reference to the effects of the severe frosts of January, 1913.

I. HARDY PALMS.

Withstand a minimum temperature of 18° to 20° F. with little or no injury.

<i>Chamærops humilis</i> (in a dozen varieties).	<i>Phoenix reclinata</i> .
<i>Cocos Alphonii</i> .	<i>Phoenix sylvestris</i> .
<i>Cocos Bonnetii</i> .	<i>Sabal Adansonii</i> .
<i>Cocos campestris</i> .	<i>Sabal Blackburniana</i> .
<i>Cocos eriospatha</i> .	<i>Sabal mexicana</i> .
<i>Cocos flexuosa</i> (of Hort.).	<i>Sabal Palmetto</i> .
<i>Cocos Gaertneri</i> .	<i>Sabal princeps</i> .
<i>Cocos Yatay</i> .	<i>Serenoa serrulata</i> .
<i>Erythea armata</i> .	<i>Trachycarpus excelsa</i> .
<i>Erythea edulis</i> .	<i>Trachycarpus Martiana</i> .
<i>Jubæa spectabilis</i> .	<i>Washingtonia gracilis</i> .
<i>Phoenix canariensis</i> .	<i>Washingtonia robusta</i> .
<i>Phoenix dactylifera</i> .	<i>Washingtonia Sonora</i> .

2738. Date palms at Old Town, San Diego.

The following require protection from sun in the interior valleys:

Livistona australis.
Livistona chinensis.
Phoenix Roebelenii.

Rhapidophyllum Hystrix.
Rhapis flabelliformis.
Rhapis humilis.

The above are rather generally found and to them may be added the following, equally hardy but not yet in general cultivation:

Brabea calcareo.
Brabea Pimo.
Cocos Arechavaletana.

Cocos australis (true).
Cocos Datil.

Above are tall-growing *Cocos* of the plumosa type but hardy.

Cocos odorata.
Cocos pulposa.
Erythea Brandegei.
Erythea elegans.

Nannorhops Ritchiana.
Trachycarpus caespitosa.
Trithrinax brasiliensis.
Trithrinax campestris.

All the above can be grown wherever oranges are planted, and in addition the following are at home on the hill section of Los Angeles, in the frost-free foothills and sheltered coastal valleys like Santa Barbara and the Montecito.

II. TENDER PALMS.

Chamaedorea desmoncoides.
Chamaedorea elegans.
Cocos botryophora.
Cocos plumosa.
Cocos Mariae-Reginae.
Cocos Romanzoffiana.
Howea Belmoreana.
Howea Forsteriana.
Livistona Jenkinsoniana.

Livistona Mariae.
Phoenix rupicola.
Pritchardia Gaudichaudii.
Pritchardia pacifica.
Ptychosperma Alexandrae.
Ptychosperma Cunninghamiana (Seaforthia).
Rhopalostylis Baueri.
Rhopalostylis sapida.

The following have been recently introduced, but are not thoroughly tested:

Ceroxylon andicolum.
Copernicia australis.
Juania australis.

Livistona decipiens.
Sabal Uresana.
Sabal Exul.

[*Juania australis*, Drude, representing a monotypic genus in the Island Juan Fernandez (and for the first word of which it is named), is an unnamed palm with pinnatisect terminal lvs. allied to *Ceroxylon*: lf.-segments long and narrow, acuminate, whitish beneath, thickened on the margins: fr. globular, size of a cherry.]

ERNEST BRAUNTON.

Hardy palms in Florida.

A large proportion of the various species of palms tried by the writer in Florida have succeeded from moderately to exceedingly well. Close to 200 species belonging to some 60 genera have been in cultivation and of these more than 150 are surviving. The state itself is rich in palms for a region lying wholly outside the tropics, there being not less than fifteen native and one naturalized species, the latter the common coconut, found within its borders. A few of these, such as *Sabal Palmetto*, *Serenoa serrulata* and *Rhapidophyllum* among native forms, and one or two species of *Trachycarpus*, one or two of the dates, *Jubæa spectabilis* and *Washingtonia* should be fairly hardy, especially along the coastal region, throughout most of the northern part of the state.

Most of the palms which do well in this state succeed on ordinary pine land, but their growth would be improved if a liberal amount of muck or leaf-mold was incorporated with the soil, and a heavy mulch is always beneficial. Of course in poor soils a good fertilizer is necessary and it is an excellent plan to apply one rich in potash in the fall in order to harden up the growth for winter.

Nearly all the palms must be propagated from seed; only a few are caespitose, such as *chrysalidocarpus*, *rhapis*, most of the *phoenix* and *chamaedoreas*, and these can often be propagated from suckers. When these are thrown out above the ground it is best to make an incision at their bases and set a flower-pot underneath, mounding up with earth around the sucker, when it

will generally throw out roots into the pot, after which it may be severed and the whole removed.

The entire state is subject to "northerners" during which the wind blows from the northwest, and cold weather and frost may occur in any part of the state. A large part of the palms which can be grown in Florida are tropical and if their seeds when in the ground are subjected to such a degree of cold they are almost sure to perish. If one is propagating any considerable number of palms, it will pay to have a frame covered with a sash or sashes. This can be sunk in the ground if necessary; the seeds should be planted in good soil, and during cold nights the whole may be heavily covered with fertilizer sacks. It should have a southern exposure and be well protected from the wind. In the southern part of the state such a pit, if covered early and thoroughly on cold nights, will generally answer all purposes, but if one could have a small glass house with

2739. A digitate-leaved palm, one of the best palms for small conservatories—*Rhapis flabelliformis*.

a bench along one side it would be better. The space in front and below it could be closed up and under the shelf a small kerosene stove or lamp could be kept going during cold nights. This would furnish bottom heat for the seeds planted on the bench and thus insure their germination.

Fairly good-sized palms are best for planting in the open ground, say from 4- or 5-inch pots. Water well and mulch, then shelter by setting palmetto leaves around the plant so as to shade it. In case of danger of frost, mound up around the stem to above the growing point with dry soil and if the leaves are frozen the plant will not be seriously injured.

The following notes are drawn from experience in the cultivation of these palms in central and southern Florida.

Acelorraphe Wrightii grows in marl land on the southern shore of the mainland of Florida. It forms very dense, attractive clumps 30 feet or more across.

Acrocomia. Rapid growers, and *A. Totai* is hardy in the southern half of Florida. It will not grow in dry or poor soils, but thrives in rich moist lands. Like most palms, this species is very responsive to an application of commercial fertilizer—from a pound to ten pounds according to the size of the plant. *A. media*, from Porto Rico, is an exceptionally vigorous grower.

Archontophoenix. The two species, *A. Cunninghamii* and *A. Alexandrae*, which are such favorites in the North, are among the best palms in Florida, and will, without doubt, become favorites in the lower third of the state. They succeed well in shade or sunshine, on pine or hammock land, and are fairly rapid growers, the former being somewhat the stronger plant.

Areca glandiformis is a superb, rapid-growing palm which grows well in pine land; *A. triandra* is an elegant species, which should probably be grown in the shade, and the same may be said of *A. Allicia*. All are tropical.

Arenga saccharifera is a noble palm and does well in pine land.

Attalea. Prefers rich soil and if well grown makes magnificent specimens. *A. Cohune* succeeds well in southern Florida, and also *A. gomphococca*.

Bactris. None of the species thrives in southern Florida.

Caryota. Several species are cultivated in lower Florida. Sometimes the specimens do well; at other times they fail. When in bloom they are among the most striking of palms. The ends of the leaflets are subject to a blight which decidedly injures the growth of many specimens.

Chamaedorea. Lovely, often cespitose palms with reed-like stems. They are probably all tender, and do well in southern Florida in sheltered, more or less shaded places.

Chamærops. All of these do well in southern Florida and would doubtless prove hardy throughout a large part of the state. They are slow growers, especially until they attain to considerable size. *C. humilis* thrives best on high dry soils. The flowers, resembling a flat yellow fringe from a distance, appear in March, and exhale a very strong, aromatic perfume. All produce numerous suckers which should not be removed. Planted in small groups 10 to 15 feet apart, they soon form very beautiful specimens which look best in the foreground of magnolias or other taller palms. Each plant should receive a mulch of stable manure in March or April, and some good commercial fertilizers during the rainy season.

Chrysalidocarpus lutescens is a well-known palm in the North, and in southern Florida it forms large clumps 20 or 25 feet high.

Coccothrinax jucunda and *C. Garberi* are elegant, low-growing palms from the extreme southern part of Florida and are as easily grown as the species of *Thrinax*.

Cocos. All species of *Cocos* do well in southern Florida except *C. insignis* and *C. Weddelliana*. The common coconut, *C. nucifera*, save that it sometimes is injured by frost, does as well as in many parts of the tropics and it is grown more than all other palms put together. It ripens nuts and is becoming naturalized in Dade and Monroe counties. *C. plumosa* and the species of its section are beautiful, rapid growers and all the australis section succeed admirably. The various species are sometimes attacked by what is apparently a fungous disease appearing as brown streaks in the young leaves. The only remedy is to pull the leaves apart and cut out the injured young leaf back as near the growing bud as possible. This may have to be repeated once or twice. This same disease attacks the royal palms, which may be treated in the same way. All the species do well on high pine land, if well fertilized and watered during long dry spells. The tall-growing, slender-stemmed species like *C. plumosa*, *C. flexuosa*, *C. Romanzoffiana* and *C. coronata* are hardy as far north as central Florida. The species and varieties of the australis group—*C. australis*, *C. eriospatha*, *C. Datil*, *C. Gaertneri*, *C. Yatay*—are better adapted to high pine land than most palms. They soon form beautiful specimens, flower regularly when only a few years old, and bear large bunches of edible fruit, sometimes as large as a big cherry or small plum. The fertilizers to be used for these palms should be equally rich in ammonia, phosphoric acid and potash. This should be applied in the months of December, January, and February. All the old dry leaves, spathes and fruit-stems should be removed at the end of September.

Copernicia. A fine group of fan-leaved palms which is abundantly developed in Cuba.

Corypha. None of the species seems to thrive in Florida.

Demonorops. Tender, and easily killed during cold spells in lower Florida.

Dictyosperma. Two species are grown in southern Florida, *D. rubra* and *D. alba*. Both are fine palms and when established are strong growers and soon make bold and beautiful specimens. They are harder than some of the tropical species.

Elæis, the oil-palm of tropical Africa, is grown to some extent in lower Florida and it has produced perfect seeds. It seems to be a rank feeder and if planted in pine land should be well fertilized.

Erythea edulis and *E. armata* should be hardy throughout the southern half of Florida.

Gaussia princeps grows abundantly on limestone cliffs in the mountains of Cuba, and promises to do well also in southern Florida.

Geonoma. Species of this genus are doing moderately well in southern Florida planted in a shaded situation in the edge of the hammock.

Hedysepe Canterburyana is doing excellently in southern Florida and should be hardy throughout the greater part of the state.

Howea. These palms do not seem to do well in Florida, although they should be hardy over the southern half of the state.

Hydriastele Wendlandiana is a handsome, rapid-growing palm which promises well when planted in partial shade in fairly good pine land. As it is a native of Queensland it is, no doubt, tender.

Hyophorbe amaricaulis and *H. Verschaffeltii* are strikingly ornamental, richly colored palms which are doing fairly well in lower Florida. Both have bottle-shaped caudices.

Hyphæne Schatan has been introduced into southern Florida and does well in pine land, although very tender. It has massive leaves with spiny-edged petioles.

Jubæa. The species grow very slowly. *J. spectabilis* should be hardy throughout Florida.

Latania. The *latanias* are among our noblest and most beautiful palms; *L. Loddigesii* is very robust and *L. Commersonii*, although

not so strong a grower, is very fine. They will grow in salty soil and stand salt air well, but are tender.

Licuala. Tropical palms from the Orient which do not do well in southern Florida. *L. grandis* and one or two others have succeeded for a short time, but soon die.

Livistona. Most of the species do well in southern Florida. *L. chinensis* and *L. australis* will probably prove hardy as far north as latitude 27°. They require rich moist soil. *L. rotundifolia*, *L. alissima*, *L. Hoogendorpii*, *L. subglobosa* and *L. Jenkinsiana* are fine tropical species.

Martinezia caryotafolia is cultivated in southern Florida and seems to do best in a sheltered and partly shaded situation.

Nipa. This grows successfully in brackish marshes in southern Florida, although often destroyed by land crabs.

Oreodoxa. The species of this genus are unsurpassed for majesty and grace by anything in the vegetable kingdom. The common royal palm, *O. regia*, grows in the greatest abundance almost everywhere throughout the island of Cuba and is universally respected and loved by the natives. It is generally a rather slender tree, rarely over 70 feet high and, as a rule, has a swelling somewhere along the stem. O. F. Cook considers that the species growing in the extreme lower end of this state is distinct and has named it *Roystonea floridana*. It grows to a height of 100 feet or more, the stem is not often swollen and the seeds are smaller than those of Cuban trees. Both flourish on rich or moist soil over the lower third of the state. *O. Borinquena* is a stouter species which will probably do well where the Cuban species will, while *O. oleracea* is a lofty growing species that is much tenderer. They generally do not succeed well on pine land but will do fairly well if abundantly mulched and treated with buck, especially if they are irrigated.

Phoenix. All species and varieties of the date palm grow exceedingly well in Florida, and all the smaller kinds growing in tufts fruit abundantly, as do also the hybrids between *P. dactylifera* and *P. sylvestris*. They flourish equally well on pine, hammock or swamp land, even in brackish marshes. *P. dactylifera*, *P. canariensis* and *P. sylvestris* are hardy in northern Florida. Hybrids between these three are numerous. The tufted kinds like *P. reclinata*, *P. paludosa*, *P. farinifera* and their varieties form magnificent specimens of medium size when well cared for. *P. humilis* and *P. Roebelenii* grow best in rich moist somewhat shaded soil. For the large-growing species like *P. canariensis* and *P. sylvestris*, and for all the large-growing palmettos (sabals) it is necessary to make special preparations before setting them out on high pine land. Dig a hole 6 feet deep and 6 feet wide. Old tin cans, bones, rotten oak wood should be placed at the bottom, then stable manure mixed with clay should follow. The upper 2 feet of the hole should be filled in with surface soil mixed with well-rotted manure. Three- or 4-foot specimens should be set out in such places. They will grow very fast and will form beautiful specimens within a few years. On low moist soils and in hammock woods, such preparations are not so necessary. But wherever planted, all palms need two good applications of fertilizer each year. A good plan is to mulch the plants in April and May with stable manure. This should be dug in around the plants in October, and a good application of commercial fertilizer rich in potash should follow immediately. Potash serves to harden the plants and makes them more resistant to cold.

Phytelephas macrocarpa succeeds well in southern Florida.

Prithardtia. A few species of magnificent fan-leaved palms from the South Seas, all of which are excessively tender in Florida. They can be grown in the more tropical parts of the state in sheltered places but are liable to have their leaves disfigured by frost.

Pseudophoenix Sargentii has been found rather abundantly on Elliott's Key, one of the northernmost of the lower chain. It is cultivated somewhat in southern Florida and when young is rather attractive but when old it has exceedingly dark foliage and is rather stiff and formal.

Ptychosperma Macarthurii is an elegant tufted palm which succeeds finely in southern Florida. It should have partial shade and shelter and if well fertilized it soon becomes a most attractive object.

Rhapidoxyllum. This beautiful little palm is a native of northern and central Florida where it grows on low shaded ground. The low stems are covered with a very thick spongy mass of a peat-like substance. It is easily removed and thrives in any soil, even on high pine land. It does not need much water or fertilizer.

Rhapis. Slender, tufted, low-growing palms which are hardy in Florida and require moist soil and a shady place. *R. humilis* is the most elegant species, growing in dense clumps about 7 feet high. *R. flabelliformis* is more inclined to spread.

Roscheria. Young plants of *R. melanochates* do well in southern Florida, in sheltered situations.

Sabal. In good rich moist soil all the sabals grow well and soon form fine specimens. Such soils need no special care before planting, but good applications of fertilizers are necessary, if fine-looking and thrifty specimens are desired. All do well, however, on high dry pine land soils if well watered and fertilized. If not well taken care of they are exceedingly slow growers. *S. Blackburnianum* has immense leaves, while those of the somewhat glaucous-colored *S. mauritiforme* are scarcely of less size. *S. mexicanum* resembles the native *S. Palmetto*. There are a number of distinct varieties, such as *S. havanensis* and *S. princeps*. The species which do not form a trunk, like *S. Adansonii*, are only desirable for large palm collections.

Serenoa. Common on high pine lands as well as in rich hammocks. It grows in dense clumps and when given an opportunity to grow makes a very ornamental plant.

Stevensonia grandifolia is a magnificent palm but seems to be excessively tender in Florida. Perhaps it would succeed with protection until it attained considerable size.

Thrinax. The species of this fine genus do remarkably well in all kinds of situations and soils. They are all tropical and the beauty of the leaves is destroyed by frost. *T. Wendlandiana*, *T. floridana*, *T. microcarpa* and *T. keyensis* are natives of the extreme southern end of the state and are all fine. *T. barbadensis* and *T. Morrisii* are elegant species, the latter being dwarf. The magnificent leaves of *T. altissima* are liable to be injured by winds if planted in an exposed place.

Trachycarpus. These palms do not seem to thrive well in Florida, although a few specimens of *T. excelsus* in the central part of the state are doing well.

Versaffeltia also does not thrive in Florida.

Wallichia caryotoides thrives in shady positions in southern Florida.

Washingtonia. Three distinct species are grown in Florida. *W. robusta* is one of our finest palms, growing rapidly and vigorously in pine land and it is used to some extent for planting along streets and roads. *W. filifera* is not so handsome a tree or so rapid a grower as *W. robusta* but it is doing well. *W. Sonora* promises well here. Everywhere in Florida where the soil is moist, the washingtonias grow to perfection. They will not thrive on high dry ground. They will occasionally require good applications of fertilizers.

CHAS. T. SIMPSON.
H. NEHRLING.

PALMERÉLLA (Dr. Edward Palmer, American botanical collector, discoverer of the original species). *Campanulacæ*. A genus of two or three species, with small blue fls. like those of a lobelia. The genus differs from *Lobelia* in the adnation of the stamens, as well as in the entire or closed corolla-tube, at least its upper part, but which soon splits from the base upward for a good distance, and before withering the lower part of the corolla is much disposed to separate into five claws (liberating also the lower part of the filaments); filaments adnate to the corolla-tube to near the throat and then monadelphous and adnate on one side or the other, or free: nectary an imperfect tubular cavity in the throat of the corolla.—Herbs of S. Calif. and Mex., very little known horticulturally.

débilis, Gray. Slender glabrous branching perennial herb, 2 ft. high, very leafy: lvs. alternate, linear-lanceolate, entire, sessile, 2-3 in. long; floral ones gradually reduced to bracts: raceme lax, few-flid.; corolla-tube whitish, 9 lines long, lobes light blue, 2 of them smaller than the others, the larger ones 3-4 lines long. S. Calif. and Low. Calif. Var. *serrata*, Gray, was offered in 1881 but it is probably not in cult.: infl. and corolla-tube somewhat puberulent: lvs. (except the upper ones) sharp-serrate, the lowest spatulate and obovate. S. Calif.

L. H. B.

PALMETTO: *Sabal*.

PALMS, POPULAR NAMES OF: *Alexandra P.*, *Archontophoenix Alexandræ*. *Assai P.*, *Euterpe edulis*. *Betel-nut P.*, *Areca Catechu*. *Blue P.*, *Erythea armata*. *Blue Palmetto*, *Rhapidophyllum*. *Bourbon P.*, *Latania*. *Broom P.*, *Attalea funifera* and *Thrinax argentea*. *Cabbage P.*, *Euterpe oleracea*. *Club P.*, *Cordylina*. *Coconut P.*, *Cocos nucifera*; *Double Coconut* or *Sea Coconut P.*, *Lodoicea*. *Coquito P.*, *Jubæa spectabilis*. *Corojo P.*, *Acrocomia sclerocarpa*. *Curly P.*, *Howea Belmoreana*. *Date P.*, *Phoenix dactylifera*. *European P.*, *Chamærops humilis*. *Fan P.*, any species with fan-shaped, rather than pinnate lvs. *Fern P.*, *Cycas*. *Fish-tail P.*, *Caryota urens*. *Flat P.*, *Howea Forsteriana*. *Guadeloupe P.*, *Erythea edulis*. *Gru-gru P.*, *Astrocaryum vulgare* and *Acrocomia sclerocarpa*. *Hemp P.*, *Chamærops excelsa*. *Ivory-nut P.*, *Phytelephas macrocarpa*. *Needle P.*, *Rhapidophyllum*. *Nikau P.*, *Rhopalostylis*. *Nipa P.*, *Nipa*. *Norfolk Island P.*, *Rhopalostylis Baueri*. *Oil P.*, *Elæis guineensis*; also *Cocos butyracea*, etc. *Palmetto P.*, *Sabal*, *Serenoa*. *Panama-hat P.*, *Carludovica palmata*. *Para P.*, *Euterpe edulis*. *Raffia P.*, *Raphia*. *Royal P.*, *Oreodoxa regia*. *Sago P.*, various species of *Metroxylon* and *Cycas*. *Savannah P.*, *Sabal mauritiformis*. *Saw P.*, or *Palmetto*, *Serenoa*. *Talipot P.*, *Corypha umbraculifera*. *Thatch P.*, *Sabal Blackburniana*; *Howea Forsteriana*. *Toddy P.*, *Caryota urens*. *Umbrella P.*, *Hedyoscepe Canterburyana*. *Walking-stick P.*, *Bacularia monostachya*. *Wax P.*,

Ceroxylon. *Wine P.* of E. Indies, *Caryota urens*, *Phoenix sylvestris* and *Borassus flabelliformis*; of New Granada, *Cocos butyracea*.

PALUMBÏNA (said to be from *palumbes*, wood-pigeon; from a supposed resemblance of the fls.). *Orchidacæ*. A monotypic genus greatly resembling *Oncidium*, with which it was formerly united. It differs principally in having the lateral sepals entirely united, forming a single segm. resembling the dorsal sepal in shape and size, the labellum scarcely larger than the petals and resembling them in shape.

cândida, Reichb. f. The only species is a small plant with narrow, compressed pseudobulbs, each with a single slender lf., 6-12 in. long; fls. few, small, white, in a slender raceme; sepals, petals and labellum oblong, acute, differing but little in size and shape. Guatemala. B.M. 5546. G.C. 1865:793; II. 20:233 (as *Oncidium candidum*).—May be easily grown in a temperate house. Blooms in summer, the fls. lasting a long time.

HEINRICH HASSELBRING.

PAMBÛRUS (from the Singhalese name *Pamburu*). *Rutacæ*, tribe *Citrea*. Small trees distantly related to *Citrus* but bearing frs. filled with gum: young branches often angled; older ones rounded, spines solitary or paired in the axils of the lvs.: lvs. simple, thick, gray-green: fls. 4-5-parted (usually 4) with 8-10 stamens; pistil supported on a subcylindric disk.—Only one species is known.

missionis, Swingle (*Limonia missionis*, Wall. ex Wight. *Atalantia missionis*, Oliver). Lvs. simple, elliptic-oblong, short-petioled, showing veins only very obscurely, wrinkling at the margins on drying: fls. in axillary racemes, shorter than the lvs.; filaments slender, anthers linear-oblong, disk long and slender; ovary 4-5-celled, with 2 ovules in each cell: fr. 1 in. diam., filled with a mucilaginous fluid. Ill. Wight, Ill. Ind. Bot. v. 3, pl. 33. Swingle, Journ. Wash. Acad. 6:336.—This tree occurs in India and Ceylon in sandy soil near the seacoast. It should be tested as a stock for *Citrus*. The wood is light-colored, but when variegated is used for furniture.

WALTER T. SWINGLE.

PAMPAS-GRASS (*Cortaderia argentea*, which see. Vol. II, p. 856.). A showy tall perennial subtropical grass grown for its whitish fluffy plumes of inflorescence; native in Argentina and southern Brazil.

The growing of pampas plumes for profit in California has been undertaken for over forty years. Pampas-grass was introduced into the United States about 1848. In the northern states it is frequently planted on the lawn in summer, and upon the approach of cold weather transferred in a tub to a cellar for winter protection. In California, a hill will sometimes attain a height of 20 feet, a diameter as great, and a weight of 2,000 pounds. Such plants would be very inconvenient for our northern friends to handle in the cellar.

Plants are easily produced from seed, but as the sex and variety are very uncertain, stock is usually increased by dividing the female plants, the plumes of which are much more beautiful than those of the male. The growing of pampas-grass in North America on a commercial scale dates from 1874, when the difference in sex was discovered. In 1872 the writer sowed seed which in two years gave several hundred plume-bearing plants. Even then the variations in color and fineness were very marked. In 1874 it was found that by pulling the immature plumes from the sheaths and exposing them to the hot sun, the male plumes would hang heavily like oats, while the female plumes would become fluffy, and light and airy. In November, 1874, samples of the female plumes were sent to Peter Henderson & Co., New York. Three hundred were ordered at once, and the following day instructions were received to double the order and send by express. This was the first lot of good pampas

LXXXIII. An avenue of palms in southern Florida.—*Oreodoxa regia*.

ever sent east from California, and was the beginning of the present pampas industry. The writer's plantation was increased each year until 1889, when it comprised about 5,000 hills. There were a number of other extensive plantations in the neighborhood of Santa Barbara. The crop of 1889 was estimated at 1,000,000 plumes. The demand has been good, but the prices have never been so high as at the beginning of the industry. The first prices were \$200 for 1,000 plumes. The decrease in price was gradual until 1886, when sales were slow at \$30 for 1,000 plumes. Some of the growers did not harvest their crops that year, and destroyed their plants. In the fall of 1887 plumes were in demand at \$40 the 1,000, and in 1888 they were scarce at \$50 and \$60 the 1,000. The following spring there was an increase in acreage. Since then the industry has had its ups and downs, and the price has ruled low for several years, the present prices being \$9 to \$10 for first-class, and \$5 to \$6 for second size.

Pampas-grass should be put on the best valley land, and set 10 by 16 feet apart. Before planting, the ground should be deeply plowed and put in first-class condition. In selecting stock, divide only female plants that produce the finest white plumes. Young hills produce the best plants. From old hills the best plants are obtained around the outside, those in the center of the stool being mostly worthless unless planted in large clumps. Some plumes will be produced the first year after planting. They will not be first-class, but are worth saving. The second year, if well grown, they should produce 80 to 150 plumes to the hill. Not all plantations will yield this much. The third and fourth years there will not be much change in the yield. As a plant gets older the plumes are larger but the yield is less. After 8 to 10 years a quantity of dead matter will have accumulated, and the hills should be trimmed or burned.

The appearance of the plumes is a signal for great activity among those who have large fields. The grass should be so trimmed early in September, before the plumes appear, that each hill will be easy of access. Young plants ripen their plumes two or three weeks earlier than old ones, and some varieties are earlier than others. It requires exercise of judgment to pick the plumes at the proper time. They are generally ready when they are exposed from the husk a few inches and have a fluffy look. It is well to try a few at this stage, and if they cure well at the stem end when dry they are all right, but if they do not become fluffy at the stem end they have been picked too young. If the plume looks dark and seedy at the top when cured, it was too old when picked. Some varieties, especially those producing very long plumes, should be allowed to remain somewhat longer on the plant than those of the short-plumed varieties. By trying a few of each variety, the time of ripening can soon be ascertained. Some varieties are pulled from the husk in the field; others have to be hauled to husking benches, where the husk or sheath is removed. Some planters husk them like corn: others use a knife set in such a way as to split the husk without injuring the plume. When the husk has been split, a quick jerk or strike on the table will extract the plume. The plumes are then taken to the drying ground and evenly spread in long rows. This ground should be made smooth and free from any trash that is liable to adhere to the plumes. Clean stubble ground is the best. The plumes are left on the ground three days and two nights to cure, and are turned and shaken once each day. They are next packed away as broadly and smoothly as possible on shelves in a dry building, where they should lie ten days or two weeks, or until the stems are thoroughly dried, at which time they are ready for market. They are packed in two grades: the first class, having plumes 26 inches long and over, clear of stem (sometimes as long as 45 inches), is packed in cases that hold three-quarters of a ton and contain 3,000 plumes; second-class stock is packed

in cases of the same size, the plumes being 17 to 26 inches long clear of stem, and 3,000 in each case. If shipping by express, the writer uses bales of about 2,000 plumes, covered with canvas or burlap and some light strips of wood at the corners. If the plumes are packed smoothly and evenly they will withstand heavy pressure. Careful all-round cultivation is necessary to produce good plumes.

The best market at present is London, the next Hamburg. Berlin, Denmark, New York and Philadelphia take a few. Pampas plumes are colored in London. In America the pure white plumes give the best satisfaction.

JOSEPH SEXTON.

PANAX (old Greek name, meaning *all healing* or a panacea). *Araliaceæ*. A genus of seven or eight species of hardy perennials none of which is of cultural importance except *P. quinquefolium*, Linn., the GINSENG, which see (Vol. III). They have aromatic roots, digitately compound leaves and greenish white flowers in a terminal umbel. They are all natives of the North Temperate Zone, mostly in Asia and North American. For an account of the tender plants heretofore included in this genus, see *Polyscias*.

The genus as now defined is distinguished by the thickish roots or tubers from which arise erect simple

2740. *Panax trifolium*.

short sts. bearing 1 whorl of 3 digitate lvs. which have 3 or 5 lfts.: umbels terminal and solitary, simple, bearing small white or greenish polygamous fls.; calyx obscurely 5-toothed; petals 5, spreading; stamens 5, alternating with petals; styles 2 or 3: fr. a 2- or 3-seeded little drupe. Two species are native in the eastern U. S. and Canada. *P. quinquefolium*, Linn. (*Ginseng quinquefolium*, Wood. *Aralia quinquefolia*, Decne. & Planch.).

GINSENG, growing in rich woods Que. to Minn. and south to Ala.: about 1 ft. high from a more or less branching thick root: lfts. usually 5, stalked, the basal pair much smaller than the others, all ovate or obovate, dentate, acuminate: peduncle an inch or two long, bearing a 6-20-flid. umbel; styles usually 2: fr. bright red. *P. trifolium*, Linn. (*Ginseng trifolium*, Wood. *Aralia trifolia*, Decne. & Planch.), GROUND-NUT (Fig. 2740), native in moist mostly low or flat woods, Nova Scotia to Iowa and Ga.: delicate little plant about 6 in. high, with a deep globular blackish tuber or root about 1/2 in. diam.: lfts. mostly 3, sessile, oval to oblanceolate, obtuse, serrate: peduncles an inch or two long, bearing a few whitish often monœcious fls.; styles usually 3: fr. 3-angled or 2-sided, yellowish. An attractive but not showy early spring bloomer, suitable for colonizing in moist shady places.

L. H. B.

PANCRACTIUM (Greek, *all-powerful*; referring to supposed medicinal value). *Amaryllidaceæ*. Attractive summer- and winter-flowering bulbs, bloomed inside or some of them grown outside in mild climates with protection.

Very like *Hymenocallis*, being the Old World representatives of this group, differing botanically in having many superposed ovules in each cell rather than (as in

Hymenocallis) 2 basal collateral ovules. Bulb tunicated: lvs. linear to lorate, mostly appearing with the fls., the latter in an umbel terminating an erect solid mostly stout scape or peduncle and white or greenish; perianth funnel-shaped, with a long tube, the segms. equal, short and spreading or ascending; stamens inserted at the throat of the perianth and joined by a web or cup: fr. a loculicidally 3-valved caps. with

'2741. *Pancratium*: types of three sections.

At the right, the short perianth-tube and small staminal cup of *P. illyricum*. At the left, the relatively short tube and large cup of *P. maritimum*. At the top, the long tube and small cup of *P. verecundum*, to which *P. tortuosum* is very closely allied. (From B.M. and B.R.)

angled black seeds.—Species 14 or more in the Medit. region, eastward to India and southward in Afr. *Pancratiums* and *hymenocallis*, sometimes called spider-lilies or spirit-lilies, form a beautiful group of bulbs, hardy or tender, some blooming in winter, others in summer, and all characterized by the beautiful floral structure known as a staminal cup. This cup is white and has the texture of petals. It is fringed or toothed in a great variety of ways. The filaments growing out of the cup are long or short. The perianth-segms. are usually long, slender, and gracefully recurved.

The species of *pancratium*, coming as they do from Africa, southern Asia, and southern Europe, in most cases need a high temperature while in growth and a period of rest after flowering. The "rest" is secured by placing them in a house where there is plenty of ventilation and a cooler temperature. Gradually withhold water, giving only just sufficient to keep in a life-like state. The bulbs should be kept in this semi-dry state through the winter. After the middle of January, they may be repotted or have a top-dressing. For a compost, use a good strong loamy soil four parts, well-decayed cow-manure one part. When the roots get well through this compost, liquid manure will be useful once a week. Those bulbs that do not need repotting may have some of the old compost removed, but care must be taken not to injure any of the roots. They may now be placed in a house with a night temperature of 60°. As growth progresses, the temperature may be increased at night

to 65° or 70° and at day, with sun, from 80° to 85°. Keep well up to the glass so their growth will be as stocky as possible. In their growing season, they will consume large quantities of water, and they should never become entirely dry at the roots. Give plenty of syringing in bright weather, and ventilate so as to keep temperature right. When they show flower, they may be given a drier and more airy house. For a winter temperature, 50° to 55° will be high enough, with about 10° increase with sunshine.—*Pancratiums* can be increased by offsets and seed. The offsets may be separated from the parent plant and placed rather close in pans in a light mixture of equal parts of leaf-mold, peat, and sand, given good drainage. When they have made a few roots, they may be potted up into small pots and grown on. When sowing seed, prepare some pans by giving plenty of drainage and filling with a mixture of leaf-mold, peat, and sand, screening some of it fine for the top. Sprinkle the seed all over the surface and cover with the fine mixture, press firmly and give ordinary stove temperature. Maintain an even moisture with these pans. When they start to come up, place well up to the glass. When large enough, prick out into other pans or flats, using a heavier compost. Pot off when larger and grow without rest through the winter. In the spring they will require 5- or 6-inch pots. Their management from this on will be that already mentioned. Give light fumigations often in order to keep down aphids and thrips. Scale and mealy-bug, which often get into the axils of the leaves, can be removed by the use of a soft brush. (J. J. M. Farrell.)

A. *Perianth-tube* 3-6 in. long.

B. *Segms.* more than 2 in. long.

tortuosum, Herb. Bulb globose, 2 in. or less diam., with long cylindrical neck: lvs. 6-12, linear, spirally twisted, 1 ft. or less long, with the fls., the latter 2-4 in an umbel: perianth-tube 5-6 in. long, the segms. linear and ascending, greenish; staminal cup over 1 in. long, distinctly toothed between the short free tips of the filaments. Autumn and winter. Arabia and Egypt.

BB. *Segms.* 1½ in. long.

verecundum, Ait. Fig. 2741. Bulb globose, 2 in. diam., with long cylindrical neck: lvs. 6-10, sword-shaped, appearing with the fls.: peduncle compressed, 1 ft. long; fls. 2-6, white, with greenish tube, fragrant; tube 3-4 in. long; segms. linear; staminal cup or corona 1 in. or less long, bifid between the free filaments. India. B.R. 413.

AA. *Perianth-tube* 1-3 in. long.

B. *Staminal cup* small, 3-4 lines long.

illyricum, Linn. Fig. 2741. Bulb very large: lvs. 5-6, strap-shaped, glaucous, 1½-2 in. wide, appearing with the fls.: scape 1 ft. or more long; fls. white, 6-12 in a centripetal umbel; perianth-tube 1 in. long, green; segms. 1½ in. long; staminal cup with long narrow, 2-cut teeth; free portion of filaments 6-9 lines long: seeds not compressed. Summer. Corsica, Sardinia, Malta, S. Italy. B.M. 718. Gn. 48, p. 246.—Hardiest, commonest and perhaps the best.

BB. *Staminal cup* large, 1 in. long.

maritimum, Linn. Figs. 2741 and 1936, Vol. III. Bulb globose, 2-3 in. diam. and with a neck: lvs. 5-6, linear, glaucous, persistent, becoming 2-2½ ft. long: fls. white, very fragrant, 5-10 in an umbel on a compressed scape or peduncle; perianth-tube 2-3 in. long; segms. linear, 1½ in. long, ascending; staminal cup very prominent, the teeth short, triangular and regular; free part of filaments 3 lines long. Spain to Syria. B.R. 161.

WILHELM MILLER.

L. H. B.†

PANDANUS (Latinized form of a Malayan name). *Pandanaceæ*. SCREW-PINE. Tropical plants often attaining the size of trees, and remarkable for their stilt-like aerial roots, and the perfect spiral arrangement of their long sword-shaped leaves. They are planted in tropical and subtropical regions, and are also grown as pot and tub specimens for greenhouse, residence, veranda and lawn decoration, where their stiff clustered foliage gives them a formal decorative character.

The family Pandanaceæ comprises 3 genera (Warburg, in Engler's *Das Pflanzenreich*, IV:9 [hft. 3] 1900): Sararanga, with 2 species, in the S. Sea Is. and Philippines; Freycinetia, more than 100 species, from Ceylon to Philippines, Austral., New Zeal., and Hawaii; Pandanus, with probably 250 species now described, in Trop. Afr., India, Austral., islands of the Indian Ocean and the Pacific. Pandanus comprises small trees or shrubs, erect or rarely prostrate, usually forked, the trunk annular, often producing aerial roots: lvs. linear and acute, commonly sharp-dentate or prickly on margin and midrib, the base usually vaginate but not petioled: fls. dioecious, in axillary or terminal spadices, the male spadices branched, the female always terminal and racemose or solitary, the leafy spadix-bracts usually colored; perianth none; stamens many in male fls., the filaments free or connate; staminodes in female fls. small or none, the ovary free or joined to those of adjacent fls.; ovule solitary and erect; fr. a syncarpium of free or connate angular woody or fleshy drupes, sometimes large (1 ft. long) and cone-like.—The screw-pines are characteristic plants in many tropical regions, with long ringed trunks, bracing roots, and crowns of dracena-like foliage. The lvs. of some species are used in manufacture of bagging and in other ways, and of some kinds the frs. are eaten. Some of them have very fragrant fls., and of others the frs. or other parts are fetid. Two species are important in cult., *P. Veitchii* and *P. utilis*, the former variegated, the latter not. (See Figs. 2742–2744.) Young plants of these are amongst the most popular foliage plants for home decoration. They are especially suited for fern-pans and table-decoration. They are grown to a very large extent by wholesale florists and palm specialists.

2742. *Pandanus Veitchii*.

Every conservatory has them, and occasionally *P. utilis* is grown to a considerable age and height for the sake of a perfect specimen of the spiral habit of growth on a large scale. (See Fig. 2743.) Some of the species have red- or purple-tinted lvs., but these appear not to have become popular. In the tropics, *P. utilis* is as valuable to the natives as many palms. The frs. are edible, and the roots furnish fiber for ropes, baskets, mats and hats, as do also the lvs. which are used in

2743. *Pandanus utilis*. A young screw-pine just beginning to show the spiral character.

making paper and nets. The numbers of species in commercial cult. are very few, although many names occur in horticultural literature. Without fls. and frs., it is difficult to know what species are actually in cult., or how accurate may be the popular descriptions and illustrations. For the same reason it is impossible to construct an accurate botanical key that will be of practical use to the gardener. Some of the good garden kinds are unplaced botanically, particularly the variegated or striped-lyd. kinds, which are sterile or the fructification insufficiently studied.

Pandanuses are among the best decorative plants and they are not difficult to manage when grown under favorable conditions. They are usually at home in palm-houses, and some of the species may be treated as semi-aquatics in victoria tanks. As a rule, they thrive in much heat and with plenty of water. From the latter part of January on, these plants become active in growth. It is at this time that one must make the atmosphere of the house more congenial in the way of supplying abundance of atmospheric moisture. To supply this condition, damp down the benches, paths and under the benches two or three times a day in bright weather. Before they have made too much headway any necessary repotting should be done, such as renewing with new compost or shifting into larger pots. A good compost to use is fibrous loam four parts, well-decayed manure and leaf-mold one part each, with enough sand added to give it a porous texture. See that the pots have plenty of drainage and pot firm enough to get the new compost well around the roots. In February and on, as the days become longer and the sun more powerful, they will require more water at the roots, with frequent syringings. The temperature may be increased from 60° to 65° at night, and in late spring and summer they will need a night temperature of 70° with a rise of 10° to 15° in bright weather. During summer when the sun is powerful, they will need a little shade, but only enough to hold them in good color as they like plenty of diffused sunlight at this

period. In autumn, winter and spring, they like plenty of sunshine. When autumn comes, do less watering and syringing, as root-action is becoming less active. To keep them in good health, it is very important to use great care in watering them in the winter months, as any unskilful or careless watering will surely cause ruin. Also give ventilation strict attention at all times.—Most of the species of pandanus can be increased from suckers, that are more or less produced from the main stem. These may be taken off and a few of the bottom leaves removed, and placed singly in small pots, using a mixture of loam, peat, and sand in equal parts. Plunge in a warm propagating-bed where they may have a brisk bottom heat. The best time to increase this stock is after January. Some species are grown from seed. Seeds may be sown whenever they can be secured fresh, which is usually in the spring. Sow the seed in pans in a mixture of loam, peat, and sand in equal parts. Cover and press firmly. Keep moist, but not in a soaked condition. It will aid the germination to soak the seed twenty-four hours in tepid water. Give plenty of heat and keep shaded and they will germinate without much trouble. When large enough, pot off and keep on shifting and grow under the above cultural directions and they will form good stocky plants. (J. J. M. Farrell).

A. Foliage striped or marked with white or yellow.

1. *Veitchii*, Hort. Fig. 2742. Lvs. 2 ft. long, broader than in the common *P. utilis*, somewhat recurved, spiny-toothed, dark green in the center, margined with broad bands of white or silvery white, the apex long-

2744. *Pandanus utilis*. Young plant of a narrow-leaved graceful form.

acuminate. Polynesia; intro. by Veitch in 1868. A.F. 4:570. F. 1871, p. 177. Gn. 2, p. 501. G. 9:176; 23:565. G.L. 26:177. Gn.W. 23, suppl. May 12. G.W. 2, p. 389; 5, p. 391; 11, p. 241; 12, p. 414.—Perhaps a form of *P. tectorius*.

2. *variegatus*, Miq. St. branched, emitting roots: lvs. narrow-lanceolate, very narrowly attenuate or even filiform above, pale green, striped or variegated with white or pale green or the younger ones all white, the prickles or spines whitish and purplish. Polynesia.—Probably plants cult. as *P. javanicus* and *P. Candelabrum* var. *variegatus* belong here.

3. *Báptistii*, Hort. A leafy short-stemmed plant: lvs. narrow, nearly 1 in. wide, curved, unarmed, long-acuminate, longitudinally lined or striped with whitish or yellowish. S. Seas, probably in New Britain Isls. R.H. 1913, p. 141. G.W. 14, p. 422. Gn.W. 9:581.—Said to be a rapid grower.

4. *Sánderi*, Hort. Habit tufted, the st. being short: lvs. 30 in. long, with minute marginal spines, not unlike those of *P. Veitchii* but of denser habit, and differing much in the variegation, which in this case is golden yellow, and in place of being confined to the margin, or nearly so, it is distributed in narrow bands of yellow and green in alternation throughout the length of its lf. Timor, Malay Archipelago. G.C. III. 23:249. R.H. 1898, p. 230. G. 21:606. Gn.W. 25:123. G.W. 11, p. 242. R.B. 24, p. 180. G.M. 41:686. A.G. 19:455; 22:189. A.F. 16:887. F.E. 13:111.—Said to be a rapid grower.

AA. Foliage green, or at least not variegated or striped.

B. Spines on lf.-margins relatively small or short (sometimes wanting).

5. *pacíficus*, Hort. Lvs. broad and dark green, shining, abruptly narrowed to a tail-like apex, the margins with small fine spines. Pacific Isls. G.W. 11, p. 243; 15, p. 597.—Apparently not placed botanically, but said to be distinct and a very useful plant.

6. *tectorius*, Soland. (*P. odoratissimus*, Linn. f. *P. odoratus*, Salisb. *P. odorifer*, O. Kuntze). Height 20 and more ft., much branched, the trunk commonly flexuose and supported by aerial roots: lvs. light green, 3–5 ft. long, linear-lanceolate, abruptly produced into a long point, glaucous; spines short, white. S. Asia, islands of Indian and Pacific oceans, Austral., Philippines. G.C. III. 17:14; 32:194, 195.—A scent which is much esteemed in Java is said to be obtained from the male fls. A variable species to which many names belong, as *P. javanicus*, Hort., *P. spiralis*, R. Br., *P. Blancòii*, Kunth, *P. leucacanthus*, Hort., and *P. Bòryi*, *P. Chamissoisii*, *P. Douglasii*, *P. Linnei*, *P. Loureiri*, *P. Menziesii*, *P. Rheedii*, *P. Rumphii*, Gaud. Var. *lævis*, Warb. (*P. lævis*, Kunth. *P. moschatus*, Miq.), has somewhat glaucous and unarmed lvs. 6 ft. or more long, with a very long-acuminate apex. Var. *Samák*, Warb. (*P. Samák*, Hassk.), has narrow subulate-acuminate lvs., with margins and keel bearing slender whitish spines. *P. tectorius* is common in the Philippines near the sea and along tidal streams, and horticultural varieties are cult. in Manila.

7. *Fòrsteri*, Moore and Muell. (*P. Fosterianus*, Hort. *P. Modrei*, F. Muell.). Habit of *P. tectorius*: tall, to 30 ft., branched at top, with aerial roots: lvs. to 3 ft. long and 2 in. or more wide, short-appressed-spinulose. Lord Howe's Isl.

8. *utilis*, Bory (*P. distichus*, Hort. *P. flabelliformis*, Carr. *P. mauritianus*, Hort. *P. sativus*, Thouars). Figs. 2743–2745. The best-known species: attains 60 ft. in Madagascar, where it is native: branching: lvs. glaucous, erect, 1–2¼ ft. long, 3 in. wide, spines red. I.H. 7:265. B.M. 5014 (as *P. Candelabrum*). R.H. 1866: 270. A.F. 4:571. F.E. 15:592. G.W. 15, p. 597.—Cult. in tropics; lvs. used in making of bags, baskets,

mats, and other articles. Juvenile specimens with curving lvs. $1\frac{1}{2}$ ft. or less long, may be known as *P. elegantissimus* or by other names.

9. *heterocarpus*, Balf. f. (*P. ornatus*, Bull). Branching tree, to 20 ft., with slender trunk, very numerous roots and spreading branches: lvs. lanceolate-acuminate, dilated and clasping at the base, erect-spreading, leathery, strict, greenish, often somewhat glaucous at the base, rather flat margin covered with small red,

2745. *Pandanus utilis*. An old screw-pine in the tropics. (Adapted from "The Garden")

slightly incurved spines; lower midrib furnished from the middle with distant spines of the same character. Mascarene Isls. I.H. 19:97.

10. *pygmæus*, Thouars. Low spreading shrub, not over 2 ft. high in the center, but sending out from the base numerous horizontal, rooting, annulated branches: lvs. about $1-1\frac{1}{2}$ ft. long, spirally arranged in 3's, linear-subulate, with a clasping base; margins and keels fringed with small fuscous spines. Madagascar. B.M. 4736.—Said sometimes to be cult. as *P. graminifolius*.

11. *graminifolius*, Kurz. Lvs. 12–18 in. long by 3–4 lines wide, glaucous beneath: marginal and carinal spines minute, straight. Burma, and the true species perhaps not cult.; see No. 10. *P. graminifolius* of the trade has never been carefully distinguished from *P. pygmæus*, and, according to Nicholson the garden plant under this name is a species of Freycinetia. F.R. 2:388, where Taplin says it has a tufted much-branched habit, dark green lvs. about $\frac{1}{2}$ in. wide, not so stiff as most species; spines short, whitish. Gn.W. 20:446. G.W. 11, p. 245.

12. *furcatus*, Roxbg. (*P. horridus*, Blume. *P. spinifractus*, Dennst. *P. urophyllus*, Hance). Tree, attaining 30–40 ft., branched, with aerial roots at base: lvs. very long, attaining 6–9 ft., about 3 in. wide, somewhat glaucous beneath, the margins and keel with distantly thick spines; apex long-acuminate. India. R.H. 1879:290; 1881, pp. 174, 175.

13. *caricòsus*, Kurz. Low, cespitose: lvs. 5–8 ft. by about 2 in., glaucous beneath; margins and dorsal costæ densely spinulose-serrate, the spines very small and acute. Java. R.H. 1878, p. 405.

BB. *Spines disagreeably long.*

14. *reflexus*, C. Koch. Tree, about 15 ft., branched, the trunk 3–6 ft. tall: lvs. reflexed, acute, 5–6 ft. long, dark green, shining; spines long, whitish, those on the midrib of the lower side reversed. E. African Isls. F.R. 2:387. G.W. 11, p. 245.

15. *Vanderméeschii*, Balf. f. Tree, to 20 ft., much branched: lvs. stiff, suberect, $2\frac{1}{2}-3$ ft. long, $1\frac{1}{2}-2$ in. broad, very glaucous; margins red and thickened; spines strong, red; midrib red, prominent, spiny. Mauritius. G.C. III. 18:237.

P. amaryllifolius, Roxbg. Plant small and diffuse, supported by aerial roots: lvs. linear, somewhat 3-nerved, the apex somewhat dilated, little spinose-serrate. Probably Malayan. C.L.A. 19:131. G.W. 11, p. 243.—*P. Butayi*, Wildem. Lvs. rather broad, robust, with sharp claw-like prickles on margins and keel, said to be a beautiful decorative plant. Congo.—*P. Candellabrum*, Beauv. CANDELABRUM TREE. CHANDELIER TREE. Tree, attaining 30 ft., the lower branches horizontal and upper erect: lvs. 3 ft. by 2 in., dark green and glaucous, strongly toothed; spines brown. Trop. Afr. B.M. 5014, under this name is *P. utilis*.—Not advertised in Amer., but for the popular variegated form, see No. 2.—*P. Houletii*, Carr. Height 7–8 ft. in the wild, simple, with aerial roots: lvs. many, the blades linear and gradually acuminate-pointed, sometimes 8 ft. long and 4 in. broad, with small curved brown or purplish spines, surface dark green, tinged copper-red, or young ones purple. Singapore. B.M. 8197. R.H. 1868, p. 210.—*P. luzonensis*, Merrill. Probably the species reported in S. Afr. as *P. luzonicus*: tree, 25 ft., with erect trunk much branched above: lvs. to 6 ft. long and about 1 in. wide, long- and narrow-acuminate, the margins strongly antorsely toothed, and with stout curved spines. Philippines.—*P. nitidus*, Kurz=*P. stenophyllus*.—*P. stenophyllus*, Kurz. Shrub, 6–8 ft., with many prop-roots: lvs. 2–3 ft. or more long, 1 in. wide, shining, the margin and keel remotely pale, spinulose-serrate. Java. G.W. 11, p. 242.—*P. Wavrinianus*, Hort. Lvs. narrow, strap-shaped, recurved, dark olive-green, with irregular awl-shaped teeth. Habitat unrecorded. L. H. B.†

PANDOREA (*Pandora*, Greek mythological name). *Bignoniaceæ*. Ornamental woody vines grown for their beautiful flowers and also for their handsome foliage.

Evergreen shrubs, climbing without tendrils or roots: lvs. opposite, odd-pinnate; lfts. entire or serrate: fls. in axillary or terminal few- or many-flid. panicles; calyx small, campanulate, 5-toothed; corolla funnellform-campanulate, with imbricate lobes; stamens included, with spreading superposed anther-cells; disk thick, ring-like; ovary linear, the seeds in many series: pod oblong, with thick not keeled valves; seeds broadly elliptic, winged.—Five species from Austral. to Malay Archipelago and in S. Afr. Formerly usually included under *Tecoma*.

The pandoreas are vigorous-growing vines or lianas with handsome evergreen foliage and beautiful white or pink rather large flowers. They can be grown outdoors only in the southern states and in California and stand few degrees of frost; in the North they are sometimes a cultivated in the greenhouse. They require rich soil and sunny position. Propagation is by seeds and by greenwood cuttings under glass. See also *Bignonia* for culture.

The wonga-wonga vine, *P. australis*, is rather difficult to grow on high pine-land, as it needs a soil rich in humus. In rich soil, however, and liberally fertilized, it is a rampant grower with beautiful dark green glossy foliage. The flowers are interesting but comparatively small, and not showy. However, the species is worth cultivating for foliage alone. It must be well taken care of and well watered during the dry spring months or it will dwindle away in a very short time.

P. Ricasoliana, from Natal and Caffraria, demands a very rich soil and a heavy mulch of stable manure. Its leaves easily drop from the woody branches after a cold night, and 6° or 7° of frost kill the plant down to the ground. For this reason the vine should be banked with dry sand every fall and if killed down to the banking it must be cut off immediately or the entire plant will be lost. Plants raised from seed received under the name of *Tecoma Ricasoliana*, from Italy, are much hardier and more floriferous than those obtained from seed imported from South Africa, but the flowers of both are exactly alike. In order to flower profusely,

this species must be planted in the full sun. It usually requires a few years before it starts into a vigorous growth, and it rarely flowers before its fifth year or before it has attained considerable size. In Florida, *P. Ricasoliana* should be planted on tall stumps, or on arbors and sheds by itself, never mingled with other species. (H. Nehrling.)

A. Fls. white; lfts. 3-9.

austrâlis, Spach (*Bignônia Pandoræ*, Sims. *Técoma austrâlis*, R. Br.). **WONGA-WONGA VINE**. Evergreen high-climbing shrub: lvs. odd-pinnate; lfts. 3-9, elliptic-ovate to ovate-lanceolate, acuminate but bluntly pointed, entire or sometimes coarsely crenate, shining above, glabrous, 1-2½ in. long: panicles many-fld.; corolla funnelform-campanulate, with 5-lobed spreading limb, yellowish white, spotted violet in the throat, ¾ in. long: fr. oblong, pointed, 2-3 in. long. Spring. Austral. B.M. 865. Gn. 27, p. 94. Var. *rosea*, Hort. Fls. light rose-colored.—"Young plants and particularly seedlings have the lvs. very finely cut, nearly of the appearance of a fern and are in this stage sometimes known as *Tecoma filicifolia* or *Campsidium filicifolium*; when getting older they change entirely."—Franceschi.

jasminoides, Schumann (*Tecoma jasminoides*, Lindl. *Bignônia jasminoides*, Hort.). **BOWER PLANT OF AUSTRALIA**. Evergreen climbing shrub: lvs. odd-pinnate; lfts. 5-9, almost sessile, ovate to lanceolate, acuminate, but bluntly pointed, entire, glabrous, 1-2 in. long: panicles rather few-fld.; corolla funnelform-campanulate, the large spreading 5-lobed limb with crenate lobes, white, sometimes suffused with pink, usually rosy pink in the throat, 1½-2 in. long; calyx small, 5-lobed. Aug.-Oct. B. R. 2002. B. M. 4004. P.M. 6:199. R.H. 1895, p. 109. Var. *alba*, Hort., has larger white fls.

AA. Fls. pink; lfts. 7-11.

Ricasoliâna, Baill. (*Tecoma Mackénii*, W. Wats. *Tecoma Ricasoliâna*, Tanfani). Evergreen climbing shrub: lvs. odd-pinnate; lfts. 7-11, short-stalked, elliptic-ovate, acute or acuminate, serrate, dark green above, pale beneath, glabrous, about 1 in. long: fls. in loose, terminal panicles; corolla funnelform-campanulate, with spreading 5-lobed limb, light pink, striped red, glabrous inside and outside, 2 in. long; calyx 5-toothed: fr. linear, terete, 10-12 in. long. S. Afr. G.W. 2:343, 346. J.H.S. 39, p. 12, fig. 15.

Brycei, Rehd. (*Tecoma Brycei*, N. E. Br. *Tecoma Regiæ Sâbæ*, Franceschi). Evergreen climbing shrub: lfts. 9-11, stalked, lanceolate, acuminate, entire, glabrous, 1-2 in. long: fls. in large terminal panicles, slen-

2746. *Panicum virgatum*.

der-pedicelled; calyx glandular; corolla funnelform-campanulate, abruptly contracted at the base, light pink, netted with crimson, yellow in throat, tube 1¼ in. long, hairy inside, limb spreading, about 2 in. across. Oct.-March. Rhodesia. G.C. III. 39:344.

ALFRED REHDER.

PANICULÂRIA: *Glyceria*.

PÂNICUM (old Latin name of Italian millet, *Setaria italica*). *Gramineæ*. Annual or perennial grasses with usually flat blades and paniculate inflorescence.

Spikelets with 1 terminal perfect floret and below this a second floret which may be staminate, neutral or reduced to the sterile lemma; fertile lemma characterized by being of a much firmer texture.—An immense genus of grasses scattered over the world, especially in the tropics. Several hundred species have been described, while conservative authorities place the number at about 300. Their importance as forage grasses is very insignificant when the number of species is taken into consideration. This is largely from the fact that the species, as a rule, are not gregarious, and to the fact that they are not well represented in the meadows and prairies of temperate and northern regions. Guinea-grass and para-grass are, however, important forage grasses of the warmer regions.

A. Plant annual.

capillare, Linn. **OLD WITCH-GRASS**. A common native annual grass and weed, has been recommended for cult. on account of its ornamental purple panicle, which is ample and loose, the spikelets being borne on slender hair-like pedicels. R.H. 1890, p. 525; 1896, p. 572. Dept. Agric., Div. Agrost. Bull. 17:54.

miliaceum, Linn. **TRUE MILLET. BROOM-CORN MILLET. HOG MILLET**. A tall annual (3-4 ft.), with soft lvs., grown for fodder, but not in common use in this country: spikelets large, in a rather compact drooping panicle. Dept. Agric., Div. Agrost., Bull. 20:37.—Cult. from prehistoric times. Grown somewhat extensively in China and Japan, and S. E. Russia. Native country unknown, but probably E. Indies. More fully discussed in Dept. Agric., Farmers' Bull. No. 101. What is usually grown in the U. S. under the name of millet is *Setaria italica* and its varieties.

texanum, Buckl. **COLORADO-GRASS. TEXAS MILLET**. Commonly decumbent at base and rooting at the lower joints: culms stout, 2-6 ft.: foliage softly hairy: panicle narrow, the large, pointed, hairy spikelets somewhat crowded: seed cross-wrinkled. Dept. Agric., Div. Agrost., Bull. 7:50.—The common name refers to the Colorado River of Texas where the species is native. Sparingly cult. in the southern states.

AA. Plant perennial.

B. Blades long and narrow, not plicate.

virgatum, Linn. Fig. 2746. An upright grass with stiff culms, 2-6 ft. high, and with stout scaly rootstocks: spikelets in loose, compound panicles, usually more or less purplish, sharp-pointed; first glume half as long as spikelets, 5-7-nerved, second glume and sterile lemma of about equal length, 5-7-nerved. Native throughout U. S. except in the extreme W. R.H. 1890, p. 525; 1896, p. 572. Gn. 14, p. 215; 29, p. 235; 37, p. 245. G. 10:103. Dept. Agric., Div. Agrost. Bull. 7:60. A hardy perennial used for ornamental purposes.

máximum, Jacq. **GUINEA-GRASS**. Four to 8 ft., or sometimes taller, forming dense tufts: culms robust: nodes hairy: sheaths more or less hirsute; blades 20-30 in. long: panicle 1-2 ft. long, the long stiff branches arranged in whorls; spikelets short-pedicelled, smooth,

rather glossy, the seed minutely cross-wrinkled. Native of Afr., early intro. into the W. Indies and Trop. Amer.—Cult. for forage in the Gulf States.

barbinode, Trin. (*P. melle* of authors, not Swartz). **PARA-GRASS**. Strongly stoloniferous, as much as 20 ft. long: culms decumbent, rooting at the joints, 6–10 ft. high, robust: sheaths more or less hairy, the blades smooth, 6–20 in. long: panicles 8–15 in. long, consisting of numerous ascending racemes with rather crowded spikelets.—Intro. from Brazil. *P. numidianum*, Lam., is a closely related species of the E. Indies, sometimes confused with true para-grass.

BB. *Blades an inch or more broad, plicate: panicle narrow, the spikelets interspersed with bristles.*

sulcatum, Aubl. A tall perennial, 4–6 ft., native of Trop. Amer.: lvs. large, 1 in. or more broad, somewhat hairy, conspicuously plicate: panicle narrow, about 1 ft. long, with many ascending branches, bearing short-pedicelled spikelets throughout their length, and also scattered bristles; spikelets pointed; lower glume half, second glume two-thirds the length of the sterile lemma and fertile floret, all strongly nerved.—This and the next species belong to the section *Ptychophyllum*, which is better referred to *Setaria*.

palmifolium, Willd. (*P. plicatum* of authors, not Lam.). **PALM-GRASS**. Fig. 2747. Resembles the preceding, but lvs. broader and nearly smooth, the panicle larger and more bristly: spikelets similar. G. 3:101. Gn. 12, p. 517; 31, p. 487; 37, p. 245. R.H. 1862, p. 290.—A variegated form is figured in F.S. 17:1743–44 under the name *P. foliis niveo-vittatis*. Cult. in the S. for ornament. Native of E. Indies. Woolson, of Passaic, N. J., says it grows 4–6 ft. high in the hardy border and makes a fine, stately grass; useful for winter bouquets. This grass is known in the trade as *P. plicatum* or less commonly as *P. excurrens*, but the real *P. plicatum*, Lam., through an allied species, is a smaller, narrower-lvd. plant of no particular beauty and unknown in cult. The true *P. excurrens* = *P. plicatum*, Lam.

P. atrosanguineum of lists is apparently *Pennisetum Ruppellii*.—*P. Crus-galli* = *Echinochloa*.—*P. frumentaceum* = *Echinochloa*.—*P. germanicum* = *Setaria*.—*P. variegatum* = *Oplismenus Burmannii*. A. S. HITCHCOCK.

PANÍSEA (Greek, *entirely like*, referring to the fact that the labellum is like the other floral parts). *Orchidaceæ*. Epiphytic herbs, densely caespitose: sepals and petals somewhat similar, narrow, free; labellum narrow, with a long sigmoid-flexuous claw; column slender, broad-winged above; pollinia 4, almost without appendages.—About 4 species in the Himalayas and Assam. *P. tricallosa*, Rolfe, having pale translucent yellowish green fls.; with 3 yellow calli on the disk tipped with brown, has been grown in botanic gardens. Assam.

PANSY. A favorite garden perennial, commonly grown as an annual; prized for the beauty and individuality of its flowers. The pansy is everywhere a familiar flower. There is much character in it. The flower is often likened to a face. It appeals to personal feeling. In fact, the word pansy is only a corruption of

the French *pensee*, meaning thought. The old folk-name, heartsease, is also associated with the familiar place which the plant has occupied; it signifies remembrance. The pansy is one of the oldest of garden flowers. Parkinson mentions it as a flower-garden subject in 1629. When critical study began to be given to the kinds of plants, the pansy was so distinct from wild species that its specific identity could not be determined with precision, and, in fact, this is the case to the present day. It is generally considered, however, that it has descended from *Viola tricolor* (see *Viola*), a small perennial violet native to the cooler parts of

Europe. In its nearly normal or unimproved forms, *Viola tricolor* is now grown in gardens. (Fig. 2748.) It is a most interesting plant, because hand-some-flowered and variable. The flowers of this violet usually have three colors or shades, mostly blue, whitish and yellow, but in the different varieties one of the colors strongly predominates. A form with very small and inconspicuous flowers (var. *arvensis*) has run wild in many parts of the country.

Pansies are perennial, but they are grown practically as winter or spring annuals. Commercial growers sow the seeds in fall, and sell great quantities of the seedling plants before winter sets in. These plants are flowered in frames or cold greenhouses, or they are planted in the open for spring bloom. Plants are also started indoors in late winter for spring bloom. Pansies delight in cool, moist weather; hence the American summer is not to their liking, and they often perish. A new stock of plants is started every year.

The modern improved pansies run in strains or families rather than in definite varieties. These strains are maintained at a high grade by the best cultivation and the closest attention to selection. The seed of the best strains is necessarily expensive, for it represents much human care. The stock usually runs down quickly in other hands. It should be renewed from the seed-breeder each year if the best results are to be maintained. These fancy and high-bred strains require extra care in the growing. Most of the best strains are of European origin. They are usually known by the name of the breeder. The chief points of merit in the high-bred pansy are size of flower, brilliancy of coloring, arrangement of colors. The flowers may be self-colored (of only one color) or parti-

colored. The parti-colored flowers are of three general types: two banner petals and three central petals of different colors; petals all margined with lighter color; petals all striped. There are all grades of intermediate differences. The colors which are now found in pansies are pure white, purple-black, pure yellow, different shades of blue, purple, violet, red-purple. Pansy flowers are now grown 3 inches across. (Fig. 2749.)

With the above account may be compared Gerard's description of pansies in 1587. He pictures the heartsease or *Viola tricolor* with small violet-like flowers, the petals standing apart from each other. The "upright heartsease," or *Viola assurgens tricolor*, is represented as a stouter and more erect plant, with rounder but scarcely larger flowers. These are described as follows:

2747. *Panicum palmifolium*.

"The Hearts-ease or Pansie hath many round leaves at the first comming up; afterward they grow somewhat longer, slightly cut about the edges, trailing or creeping upon the ground: the stalks are weake and tender, whereupon grow floures in form & figure like the Violet, and for the most

2748. *Viola tricolor*. Nearly or quite the original form of pansy.

part of the same bignesse, of three sundry colours, whereof it tooke the syname *Tricolor*, that is to say, purple, yellow, and white or blew; by reason of the beauty and braverie of which colours they are very pleasing to the eye, for smel they have little or none at all. The seed is contained in little knaps of the bignesse of a Tare, which come forth after the floures be fallen, and do open

of themselves when the seed is ripe. The root is nothing else but as it were a bundle of threddy strings.

"The upright Pansie bringeth forth long leaves deeply cut in the edges, sharp-pointed, of a bleake or pale green colour, set upon slender upright stalks, cornered, jointed, or kneed a foot high or higher; whereupon grow very faire floures of three colours, viz., of purple, blew, and yellow, in shape like the common Hearts-ease, but greater and fairer; which colours are so excellently and orderly placed, that they bring great delight to the beholders, though they have little or no smell at all: for oftentimes it hapneth that the uppermost floures are differing from those that grow upon the middle of the plant, and those vary from the lowermost, as Nature list to dally with things of such beauty."

L. H. B.

Cultivation of pansies.

There are few plants more popular than the pansy. Every year the demand for the plants is greater. This flower has been cultivated for so long that its source is a matter of uncertainty. As seen at the present day, it is an artificial production, differing considerably from any known wild plant.

Pansies were probably first improved from the original type in Great Britain, where the cool and moist climate is well adapted to their cultivation, and new varieties gradually appeared with larger flowers, of varied colors. For many years, England and Scotland bore the reputation of growing the best pansies. About forty years ago, three French specialists, Bugnot of St. Brieuc, and Cassier and Trimardeau of Paris, made immense strides in developing the pansy, and their productions were a revelation to the horticultural world. Such sizes and colors were previously thought impossible. Trimardeau developed a new race with immense flowers and very hardy constitution. His strain, crossed with those of Cassier and Bugnot, has given a pansy which is superseding the older English varieties. At the present day, Germany and France lead in introducing new varieties.

It is customary at the present day to make a careful selection of seedlings for new varieties, also to propagate by the means of cuttings. The specialists are devoting much time to the improvement of the various types and strains. The flowers are being steadily improved in all points by which pansies are judged,—size, color, substance and form. Nearly all of the beautiful colors are to be found among the giant types, and the care that is being taken in the

selection of colors makes it reasonably sure that, when the choicest seed is obtained, a large percentage of the plants will come true to color. The season of blossoming has been extended, the new early-flowering strains blooming five or six weeks earlier in the spring than the old varieties.

There are many beautiful varieties of pansies and it is difficult to make a selection, but the most popular for both amateur and commercial growers are the giant flowers of the Trimardeau type, the Cassier superb strain of blotched pansies, and the Bugnots. One of the newer strains is the "Masterpiece," a very large flower with curled or ruffled petals, which are so undulated and curled that many of its blossoms appear to be double. The new upright giant five-blotched pansy called the "Princess" by Ernest Benary is entirely distinct from all other pansy strains in its great compactness, its upright growth and its hardness. Two other types which should be mentioned are the "Orchid Flowered," whose delicate orchid colors do not exist in any other strain; and the "New Early Flowering Giant" pansy, which blossoms in early March.

It is conceded by European pansy specialists who have visited the United States that the American pansy seed planted on the American soil, will produce larger and finer flowers than the foreign-grown seed of the same strain planted on the same soil.

Pansies degenerate very quickly; therefore it is very important to procure fresh seed every year from a specialist.

The four characteristics of the pansy required by the four leading pansy-growing people are as follows:

Germany: Color, substance, form, size.

Great Britain: Form, color, substance, size.

France: Substance, size, color, form.

America: Size, color, substance, form.

The success of growing a crop of pansies depends largely on having good fresh seed and on how the seed-bed is treated the first six to twelve days; for if pansy seed becomes dry after once sprouting, it is dead; and if kept too close, it will damp-off.

A coldframe is a good place in which to sow the seeds if the boards are not full of fungus; or a box 9

2749. Modern pansies. (Nearly $\frac{1}{2}$ natural size)

inches to a foot high might be made on fresh ground that is a little sandy and was well manured for a previous crop; dig and make the soil fine and water it well before sowing the seeds. Sow in drills 3 inches apart and $\frac{1}{8}$ inch deep. One ounce of seed will sow about 300 to 350 feet of drill, or 90 feet if sown broadcast. Cover the seed $\frac{1}{8}$ inch deep with fresh sand or sandy soil, pat down or roll well and give a light watering. The surface should be dusted with sulfur or grape dust to keep the damping-off fungus from starting. Cover with boards, leaving space for ventilation; or they can be covered with moss, hay, or straw, being sure to remove the covering as soon as the seed is sprouted. Pansy seed will not sprout well if kept above 75°. After sprouting and until they have the second leaves, it is a good plan to cover them with the thinnest muslin, tacked on frames. Sashes may be used if well shaded and well ventilated.

To secure the best results, pansy seed should be sown from July 10 to August 25. If plants for cut-flowers are wanted, sow the seed the first part of July. The best plants for wintering over in the field for spring sales are from seeds sown from July 10 to 20 in the northeastern states. Five or six weeks after sowing the seeds, the plants are usually large enough to be transplanted in the field, in good rich ground. The soil can hardly be made too rich, and should be in raised beds so the water will not stand on them in the winter. Plant 7 or 8 inches apart each way. If a coldframe is used, from 50 to 250 plants can be set under a 3- by 6-foot sash. If pansy plants are transplanted the first time into the place where they are wanted to grow, they will have larger flowers; for every time the roots of a pansy are disturbed, the flowers will be smaller. Just enough mulch should be applied to hide the plants from view after the ground is frozen. This mulch is taken off as soon as the frost is out of the ground in the spring.

There are from 25,000 to 28,000 seeds in one ounce of pansy seed. Growers usually allow one ounce of seed for 4,000 plants. With good fresh seed and great care, 7,000 to 8,000 plants should be obtained from one ounce of seed. For commercial purposes, pansy seed should be planted in July and August, but at this time of the year, it is too hot for the seeds to grow well. Seeds planted in the fall or early spring will give double the number of plants and require less care.

If pansies for winter blooming are desired, transplant as soon as the plants are large enough to the beds or benches in the greenhouses. They will need about the same temperature as for violets, 40° to 45° at night, and 60° in the daytime in bright weather.

Pansies are now being grown very extensively for cut-flowers in this country.

If wanted for exhibition purposes, keep the pansy plants in a low temperature till January; some freezing, even, will benefit them. Start them slowly into growth at a temperature between 30° to 40° at night, as a higher temperature will diminish the size of the flowers. A weak solution of guano or hen-manure once every two weeks will help them wonderfully. During growth and bloom, maintain a rather low, even temperature, without actual freezing, carefully avoiding extremes in temperature.

In favored localities pansies designed for early spring bloom receive no glass protection during winter, the plants from the August sowing being transplanted in the fall from the seed-bed directly into their permanent quarters. Good pansies can be grown out-of-doors without glass protection as far north as Nova Scotia. Generally, however, it is much better to winter pansies in a coldframe, especially the finer strains. Pansies in bloom should be partially shaded from the hot midday sun, particularly the fancy-colored strains, the petals of which are more delicate in texture.

CHARLES FROST.†

PAPÀVER (old Latin name, from the Greek, of dubious derivation). *Papaveraceæ*. POPPY. Well-known flower-garden plants, of brilliant but short-lived bloom.

Herbs or rarely subshrubs, annual, biennial and perennial, with milky juice, bristly or smooth and often glaucous; lvs. usually lobed or dissected in a pinnate way; peduncles long, single-fl'd., the bud usually nodding; fls. red, violet, yellow and white; sepals 2; petals usually 1; stamens numerous; ovary and caps. globose, obovate or top-shaped, dehiscing under the vertex by transverse pores between the placenta, the openings very small and valve-like; this vertex or flattened sometimes conical top or cap represents the combined radiate stigmas; placenta 4-20, projecting into the center.—Species more than 100, largely in the Medit. region, and the Armenian-Persian region and somewhat eastward, with one in the southern hemisphere; Fedde accepted 99 species in 1909 in Engler's *Das Pflanzenreich*, hft. 40 (iv:104) together with many botanical varieties and hybrids. Two or three species are indigenous in W. N. Amer. Opium is made from the milky juice of *P. somniferum*, which oozes from shallow cuts made in the young capsules. The seeds have no narcotic properties and are sold for bird food under the name of "maw seed." They also produce a valuable oil.

Poppies rank among the most popular flowers in cultivation. From their astonishing range of color, and from the formidable list of names given below, one might suppose their botany to be very complicated. It is, however, easy to understand, although the variation in some of the species is very great. There are only four species commonly cultivated and these are all remarkably distinct. They are (1) the opium poppy, (2) the corn poppy, (3) the Iceland poppy, and (4) the oriental poppy.

1. The opium poppy, *P. somniferum*, is one of the commonest and the most variable. It is annual, of tall stately habit, and recognized at once by the glaucous hue of its foliage. The flowers are the largest of any of the annual species, but unfortunately they are useless as cut-flowers because they drop their petals so quickly.

2. The corn poppy of Europe, *P. Rhæas*, is also an annual, but a dwarfer plant, with green hairy finely

2750. Shirley poppy.—One of the forms of *Papaver Rhæas*.

cut foliage and smaller flowers. It is brilliant in the fields of Europe, and it has run wild in this country. The Shirley poppies are the best strain of this species; in gardens the flowers last longer than the common *P. Rhæas* and the plants are neater when out of bloom.

3. The Iceland poppy, *P. nudicaule*, is the glory of the arctic regions. It ranges over an immense territory and varies remarkably both in the wild and the garden. Orange, red, and white are the chief colors, besides shades of yellow, but the flowers never attain the brilliant scarlet of the corn poppy. Although the Iceland poppy is perennial, it is short-lived, and is commonly treated as an annual or as a short-lived perennial. It is known for the satiny texture and crimped character of its petals. The flowers are excellent for cutting, especially if the young flowers are chosen and cut in the early morning, a principle which applies to many flowers often supposed to be useless for home decoration.

4. The oriental poppy, *P. orientale*, is a longer-lived perennial, and although it has the largest flowers of any species in the genus it has nothing like the fame of the opium poppy. However, it has the double advantage of being easily propagated by either seed or division, and it has a considerable range of color, which is said to be largely due to crosses with *P. bracteatum*. The latter differs in having large bracts below the flower.

The other species of poppy are for the fancier. The alpine poppy, *P. alpinum*, was considered by Linnæus to be a distinct species from the Iceland poppy. However, gradations occur between the typical form of *P. nudicaule* of the arctic regions and the poppy found in the Alps. The former has a yellow flower, while the common alpine poppy is white. The alpine poppy is by some regarded as an extreme form of *P. nudicaule*, characterized by a dwarfer habit and more finely divided foliage. For horticultural purposes *P. nudicaule* and *P. alpinum* should be considered to be distinct species, as many botanists indeed consider them to be. The Iceland poppy can be easily grown in the border, while the alpine poppy demands rock-garden treatment. The former does best in a moderately rich and light loam, while the latter does better in a rather poor soil. Both need full exposure to the sun, and *P. alpinum* probably needs better drainage. See No. 20, p. 2459.

The Shirley poppies are now the prevailing forms of *P. Rhæas*. The following history of the remarkable race is given by the Rev. W. Wilks in "The Garden," 57, page 385: "In 1880 I noticed in a waste corner of my garden abutting on the fields a patch of the common wild field poppy (*Papaver Rhæas*), one solitary flower of which had a very narrow edge of white. This one flower I marked and saved the seed of it alone. Next year, out of perhaps two hundred plants I had four or five on which all the flowers were edged. The best of these were marked and the seed saved, and so for several years, the flowers all the while getting a larger infusion of white to tone down the red until they arrived at quite pale pink and one plant absolutely pure white. I then set myself to change the black central portions of the flowers from black to yellow or white, and having at last fixed a strain with petals varying in color from the brightest scarlet to pure white, with all shades of pink between and all varieties of flakes and edged flowers also, but all having yellow or white stamens, anthers and pollen, and a white base." . . . Mr. Wilks then distributed it freely to all. "My ideal," he continues, "is to get a yellow *P. Rhæas*, and I have already obtained many distinct shades of salmon. The Shirley poppies have thus been obtained simply by selection and elimination. . . . Let it be noticed that true Shirley poppies (1) are single, (2) always have a white base with (3) yellow or white stamens, anthers and pollen, (4) never have the smallest particle of black about them." Double poppies and poppies with black centers may be greatly admired by some, but they

are not Shirley poppies. It is rather interesting to reflect that the gardens of the whole world—rich man's and poor man's alike—are today furnished with poppies which are the direct descendants of one single capsule of seed raised in the garden of the Shirley Vicarage so lately as August, 1880."

Hybrids between different species of Papaver are described in the monographs, but they do not appear to have given leading forms for cultivation. Hybrids have been produced between the annual and perennial species. Between the different garden varieties, crossing probably goes on continuously, and new strains are constantly arising.

For garden purposes most poppies are to be treated as annuals for best results, with the exception of *P. orientale* and *P. bracteatum*, which the gardener thinks of as one group. The oriental poppy is, in fact, the only common long-lived perennial poppy. The Iceland poppy may live for several years, but after the third year it usually degenerates. It blooms the first year from seed and the best results are usually secured the second year. The cultivation of poppies is very simple, except of course in the case of alpine species, for which special conditions must be provided. Seeds usually germinate readily, but as the young plants of the annual kinds do not transplant well, the seeds should be sown where the plants are to remain. In the Shirley and similar poppies, the plants may be thinned to stand 4 to 6 inches apart. For especially large and fine blooms, the plants should be given at least twice more room. A succession in sowings will provide a greatly extended season of bloom; removing the seed-pods will also extend the blooming-time. Open warm soil in a sunny exposure is preferred for poppies.

A. Plant prickly: caps. glabrous.

1. *aculeatum*, Thunb. (*P. gariépinum*, Burch. *P. horridum*, DC.). Annual, 1-4 ft. high, the st. nearly simple: st. branched, densely covered with spreading, rigid, unequal bristles: lvs. green, sinuately pinnatifid, the lacinations spine-tipped: fls. scarcely 2 in. across; petals scarlet-orange, unspotted: caps. glabrous, oblong-obovate. S. Afr., Austral. B.M. 3623.—The only poppy known to inhabit the southern hemisphere. Annual in S. Afr., but said to be biennial in northern botanic gardens.

AA. Plant pilose or setulose (not prickly), sometimes glabrous.

B. Species usually annual or biennial (Nos. 1-12).

C. *Herbage setulose* (or perhaps glabrous in No. 2 and in forms of No. 4) green or glaucous: foliage always incised or pinnatifid, the st.-lvs. not clasping.

D. St. elongated and leafy.

E. Caps. usually glabrous.

F. Shape of caps. club-shaped to top-shaped.

2. *californicum*, Gray. Annual, sparsely pilose-pubescent to glabrous, 1-2 ft. high: lvs. pinnately parted or

divided into toothed or 3-lobed or entire segms.: fls. 2 in. across; petals brick-red, with a green spot at the base bordered with rose-red; caps. between club- and top-shaped, flat on top, the disk 6-11-nerved. Santa Inez Mountains and southward in Calif.; also Mt. Tamalpais (near San Francisco).

FF. Shape of caps. mostly obovate or oblong.

3. *arenarium*, Bieb. Annual, 12-20 in. high, from a perpendicular root, erect, sparingly beset with bristles which are spreading on the st. and appressed on the foliage: lvs. twice pinnatisect into minute linear or linear-oblong segms.: bud obovoid or narrow-obvoid: fls. purple, with a dark spot at the base of

each petal; filaments not dilated: caps. obovate to oblong or top-shaped, with a convex disk; stigmatic rays 7-9. Sandy places in Caucasus and Caspian region.

4. *dubium*, Linn. Erect usually robust annual, hirsute, 1-2 ft. high, branched, few-flid.: lvs. glaucescent, more or less appressed setulose or often nearly glabrous above, the lower ones pinnatifid or nearly so with the segms. pinnately cut and lobes ovate or roundish or sometimes much narrower; st.-lvs. usually pinnatifid with narrow acute lobes; peduncle long; fls. pale rose, vermilion or seldom white, mostly darker in center; petals suborbicular, nearly 1 in. long; anthers violet and filaments red: caps. glabrous, obovate-oblong or oblong-clavate. Eu., N. Afr.; run wild in parts of N. Amer. Very variable, and probably little known in gardens. Var. *laevigatum*, Elk. (*P. laevigatum*, Bieb.). Glabrous or with a few small bristles: fls. purple, usually spotted; petals small, obovate: caps. narrowly top-shaped or club-shaped; stigmatic rays 8-10. Medit. to extratropical Himalaya.—It is doubtful whether the plant sold under this name is true, for in G.C. III. 5:21 it is shown with large, roundish, overlapping petals.

FFF. Shape of caps. globose.

5. *Rhœas*, Linn. CORN POPPY. Fig. 2750. Hispid annual, or rarely glabrescent, erect and branching, 1 to about 3 ft.: lvs. coarsely toothed (rarely nearly entire) to more or less pinnatifid, lanceolate in outline: bud oblong-ovoid, roundish at apex: petals orbicular or nearly so, entire or sometimes crenate or incised, cinnabar-red, deep purple to scarlet, white and variously marginate, sometimes dark-spotted, the fls. 2 in. or more across; stigmatic disk usually 10-radiate, but varying from 5-18. Eu. and Asia; run wild in N. Amer. Abundant in fields in Eu. Gn. 30, p. 297.—An immensely variable species,

from 25-30 botanical varieties and subvarieties being recognized; and the cultural variations are numberless. In cult. every shade known to the opium poppy has been reproduced in the corn poppy, but the fls. are always smaller. In the wild it varies greatly, the foliage once or twice pinnately parted, the bristles many or few, appressed or spreading, the fls. spotted or not. Up to 1886 the French poppies were considered the best strain. Since then the strain or race known as Shirley poppies has surpassed all others. This strain was developed by the Rev. W. Wilks, secretary of the Royal Horticultural Society. (See p. 2456.) Var. *ranunculiflorum*, Hort., is a strain with double fls. in various colors, self and variegated, with the petals entire, rounded and somewhat reflexed. Var. *japonicum*, Hort., is a strain intro. about 1893 from Japanese gardens, and said to have smaller and fuller fls. than ordinary and of more varied shades. They are called Japanese or Japanese pompons. *Rhœas* was the name used by the ancient Greeks and Romans for the corn poppy.

Var. *umbròsum*, Mott. (*P. umbròsum*, Hort.), has petals of a darker red than the typical *P. Rhœas*, and blackish spots. It was intro. by Vilmorin about 1891, and was considered a marked gain in productiveness. The habit is dwarf, compact, much branched. Soon after a double form was distributed. Mottet considers it a form of *P. Rhœas*, but some botanists consider it a form of *P. commutatum*, a species apparently not otherwise in garden cult. *P. umbròsum* was found growing wild in Attica.

Var. *Hoòkeri*, W. Miller (*P. Hoòkeri*, Baker). A puzzling plant found in gardens of India, and of unknown parentage. It is nearest to *P. Rhœas*, and "differs in its great size, for it forms a bushy herb 4 ft. high and upward, and in the great number of the stigmatic rays, which are 12-20, i. e., nearly double those of *P. Rhœas*; the fls., caps. and seeds also are much larger and the stigma broader in proportion." The fls. attain $3\frac{1}{2}$ in. diam., and vary from pale rose to bright crimson, with a white or black spot at the base. B.M. 6729. Gn. 29, p. 139. G.C. II. 25:9.—

Said to revert occasionally to *P. Rhœas*.

The flower-garden forms of *P. Rhœas* give remarkable color effects. Probably no plant so quickly and cheaply satisfies one's love of color.

2751. Poppies in the year 1613. Five flowers from "Hortus Eystettensis" (redrawn and reduced, indicating the antiquity of some of the main types that are popular today). *P. somniferum*.

The season of bloom, which is mostly July in the N., is rather short, but it may be considerably extended by successional sowings and by not allowing the plants to seed. Begin to sow as early

as the land can be put in condition. Cover lightly, or the germination may be unsatisfactory. Thin to 6-12 in. apart. Self-sown seeds give earlier-blooming plants.

EE. Caps. more or less setulose.

6. *pavoninum*, Fisch. & Mey. (*P. pavoninum*, Stscheckl.). PEACOCK POPPY. Annual, more or less

branched, 1 ft. or less high, hispid-pilose: lvs. pinnately parted, the divisions oblong-linear and incised-toothed, pilose: bud ovoid, nodding: fls. about 1 in. across; petals scarlet, dark-spotted: caps. minute, ovate; stigmatic rays 4-7. Sandy places of Turkestan and Afghanistan. G.C. II. 26:329.—Botanically it is very distinct by reason of 2 short horn-like appendages, one on each sepal near the tip on the back.

DD. St. elongated, sparsely leafy: biennial.

7. *caucasicum*, Bieb. Biennial, more or less setose, glaucous, 1-2 ft., the root fusiform, erect, paniculately branched: lvs. glaucous, sparsely setulose or the petiole densely so, lanceolate in outline, pinnately parted, the segms. pinatifid and lobes ovate-oblong: buds ovate: calyx glabrous or sparsely setose; petals somewhat in pairs, roundish, pale scarlet and the claw usually yellowish: caps. oblong, glabrous; stigmatic rays 3-6. Caucasus. B.M. 1675 (brick-red, not spotted).

8. *floribundum*, Desf. (*P. caucasicum* var. *floribundum*, Elk.). Glaucous biennial, yellowish, hispid, the segms. of lvs. nearly entire or dentate: fls. vermilion, the stamens ochroleucus, handsome: caps. mostly oblong, glabrous. Caucasus region. B.R. 134.

9. *persicum*, Lindl. Biennial, setose-hispid, 1-2 ft., paniculately branched, st. pyramidal: lvs. glaucous, oblong-lanceolate in outline, pinnately parted, the segms. oblong-lanceolate and entire or dentate: buds oblong; calyx setose; petals overlapping

2752. Oriental poppy, *Papaver orientale*. (× ½)

at the margin, deep red or brick-red, green-spotted at base: caps. large and broad, densely hispid; stigmatic rays 5-6. Persia. B.R. 1570 (petals brick-red, with or without a white spot at the base).—This has been, and may still be, confused in the trade with *P. caucasicum*.

CC. Herbage mostly glabrous (or very sparingly setulose), glaucous, the st.-lvs. clasping and nearly entire or incised-dentate.

10. *somniferum*, Linn. (*P. opififerum*, Forsk. *P. nigrum*, Crantz). OPIUM POPPY. Fig. 2751. Robust, glaucous and glabrous annual, 3-4 ft. high, with fls. 4-5 in. across, much larger than those of any annual

kind: lvs. oblong, unequally toothed at the base; st.-lvs. cordate at the base, sinuate-repand to dentate-serrate, very glaucous, clasping: fl.-bud ovoid-oblong, somewhat obtuse at apex, glabrous; petals orbiculate, entire, undulate or cut, from white through pink and red to purple, but not yellow or blue: caps. globose, glabrous, with a flat 8-12-lobed disk. Greece, Orient. Gn. 9, p. 197; 59, p. 127. Gt. 40, p. 609; 44, p. 593. R.H. 1893, p. 349. S.H. 2:272. G. 3:125 (as var. *nigrum*).—Sparingly run wild in N. Amer. Very variable in color of seeds, characters of caps., and form and color of petals. Var. *album*, DC. (*P. officinale*, Gmel.), has fls. and seeds white: caps. ovate-globose.

Among the double horticultural forms of *P. somniferum* are two main strains or types, the carnation-fl. and the peony-fl. (the latter *P. pæoniæflorum*, Hort.). The former has fringed petals; the latter not. Both include a wide range of color, and even a yellow form has been advertised, but this form is of doubtful authenticity. *P. Mursellii* is another strain of double fringed kinds, of which Mikado is a favorite. *P. fimbriatum* is another trade name for double fringed varieties. *P. cardinalis* is the French name of another strain of double fringed fls. Chinese poppies are a double-fl. race intro. from Chinese gardens early in 1890, and comprising dwarfier strains than previously known. R.H. 1893, p. 349. An exceptionally interesting monstrosity has occurred in which there are no petals, and the stamens are supposed to be transformed into pistils which actually ripen seed. It was figured as long ago as 1851 in F.S. 6, p. 242, and again in R.H. 1893, p. 349. It seems to be no longer advertised, but it was considered to be constant.

Among the single varieties, Danebrog is one of the most striking and popular. The white spots at the base of the petals form a cross. This variety is also known as Danish Cross, Danish Flag and Victorian Cross. Of the pure white kinds, Flag of Truce and The Bride are favorites. Mephisto is scarlet, spotted black. About a dozen other varieties are advertised by name.

11. *setigerum*, DC. (*P. somniferum* var. *setigerum*, Elk.). Differs from *P. somniferum* in having deeply incised lvs. and 7-8 stigma-lobes, the petals violet, the plant more setulose in parts: stigma-lobes 7-8.—*P. setigerum* is apparently no longer advertised, but according to Nicholson numerous fine strains have originated from it. It is usually considered a hairy form of *P. somniferum*. It is a violet-fl. plant native to the Mediterranean.

12. *gladum*, Boiss. & Hausskn. (*P. somniferum* var. *gladum*, O. Kuntze). TULIP POPPY. Annual (sometimes perennial?), glaucous and glabrous except a few small, appressed bristles along the peduncles, branched at the base: st.-lvs. broadly cordate at the base, pinnately lobed or parted; the lobes triangular, dentate; the teeth obtuse, callous, muticous: bud ovoid, somewhat attenuate at top; petals large, scarlet, spotted at the base: caps. ovate, stalked; stigmatic rays about 12. Syria to Persia. Gt. 40, p. 608, repeated in G.C. III. 10:527, R.B. 20, p. 58, S.H. 2:467 and V. 15:37. R.H. 1892, p. 463; 1893, p. 350.—The plant sold under this name reminds one immediately of a tulip because of the color and texture of the fls., but especially because of its cuplike shape. The 2 inner petals are smaller, erect, and make a loose cup. The plants grow about 12-18 in. high and produce 50-60 large fls.

BB. Species perennial.

c. Sts. elongated, more or less leafy: caps. glabrous.

D. Branching dichotomous or corymbose.

E. Fls. racemose.

13. *pilidsum*, Sibth. & Smith (*P. olympicum*, Sibth. & Smith). Perennial: sts. tall and pilose, freely branched: lvs. covered with velvety, appressed hairs;

st.-lvs. clasping, broadly oblong, lobed and serrate; radical lvs. oblong, long-petioled: fls. 2 in. across, brick-red and showy, corymbose-racemose; petals roundish, repand: caps. glabrous, oblong-club-shaped; stigmatic rays 6-7. Rocky alpine heights of Mt. Olympus in Bithynia. B.M. 4749. Gt. 1:322. Gn. 41, p. 277; 42, p. 585.

EE. Fls. solitary, or in 2's or 3's.

14. *atlanticum*, Ball (*P. rupifragum* var. *atlanticum*, Ball). Perennial: hoary and everywhere covered with copious spreading hairs except the glabrous caps.: height 1-2 ft., from a thick woody root, the sts. scape-like: lvs. oblanceolate, coarsely and irregularly crenate-serrate or pinnatifid, the segms. entire or crenate-serrate; st.-lvs. smaller and sessile: bud broadly ovate, hispid, nodding: fls. 2-3 in. across; petals orange-red or scarlet; stigmatic rays 6-8: caps. club-shaped. Morocco, 6,000-7,000 ft. B.M. 7107.

15. *rupifragum*, Boiss. & Reut. Perennial, caespitose and many stemmed: lvs. mostly radical, oblong-lanceolate in outline, pinnatisect with rounded sinuses, the segms. irregularly oblong or lanceolate and dentate or nearly entire, glabrous or pilose on the nerves, but the scape-like sts. sparsely hispid; st.-lvs. smaller and narrower: bud broadly ovoid, glabrous, nodding: fls. 5-6 in. diam., pale red: caps. oblong-clavate, glabrous, the disk 8-rayed. Spain. Gt. 2, p. 66.

DD. Branching slight, the sts. mostly peduncle-like although bearing lvs.

16. *orientale*, Linn. ORIENTAL POPPY. Figs. 2752, 2753. Plants grow 3-4 ft. high, perennial, stiff-hairy, and bear fls. sometimes 6 in. or more across: lvs. hispid, pinnately parted; lobes oblong-lanceolate, the upper lobes coarsely serrate and the lower incise-dentate: petals sometimes 6, obovate, narrowed below, scarlet with blackish base: caps. obovate, with a flat disk; stigmatic rays 13-15. Medit. region to Persia. B.M. 57. Gn. 24, p. 459; 42:584. Gn. M. 5:16. V. 12:33.—A popular perennial, now in many forms. The petals are originally apparently scarlet with a black spot. It was not until late in the 80's of the past century that this species made a decided break in color. A considerable class of hybrids with *P. bracteatum* has arisen which extends the color range through several shades of red to orange, salmon, and pale pink. Some are unspotted, some are adapted to cutting, and doubling has made some progress. Among the Latin names of varieties belonging to this class are *grandiflorum*, *hybridum*, *immaculatum*, *natum*, *splendens*, *Parkmanii*, *plenum*, *semi-plenum*, and *Sintenisii*. Several have received common or personal names. Possibly some of these names belong rather with *P. bracteatum*.—Oriental poppies are better divided after blooming, in late July, or Aug., when they are dormant; but the roots should not be disturbed if the best bloom is expected the following season. They always grow in the autumn, and these divided plants would start away and make good growth. If divided in spring, they would not recover in time to bloom. Any extra-good variety may be increased largely by cutting the roots into short pieces. This also is best accomplished in summer. No plant is more brilliant in late spring or early summer than the oriental poppy, with its large fls., silken petals and flaming colors, although its season of bloom is short.

17. *bracteatum*, Lindl. (*P. orientale* var. *bracteatum*, Ledeb.). Differs from the preceding in having large leafy bracts below the fl.: perennial, erect, setose: radical lvs. pinnate-parted, the upper ones incised, segms. lanceolate or oblong: petals sometimes 6, obovate attenuate to base, blood-red and not spotted or the claw dark violet: stigmatic disk 16-18-rayed. Medit. region to Persia. B.R. 658. G.C. 1860:647.—A variety with petals more or less united into one was mentioned in 1862-5 in F.S. 15, p. 186.

cc. Sts. very short, so that the plant is practically acaulescent, the fls. solitary on scapes.

D. Scapes very short, usually not exceeding 4 in. but sometimes twice that height.

18. *pyrenaicum*, Kern. Low and caespitose perennial, nearly stemless: lvs. green, all radical and petiolate, appressed pilose or setose (sometimes nearly glabrous), pinnately parted, the segms. ovate, ovate-lanceolate, entire, or seldom pinnatifid: scapes 1 or several, usually 2-4 in. high in the wild but sometimes twice that height, the bud ovoid, pilose, nodding: fl. yellow to orange; petals round-obovate, more or less erose, nearly 1 in. or less long: caps. oblong or obovoid, strongly ribbed. Pyrenees, Alps, Apennines.

19. *alpinum*, Linn. ALPINE POPPY. Low and caespitose perennial, nearly stemless: lvs. glaucous, all radical and petiolate, glabrous or nearly so, 2-3-pinnately parted, the ultimate segms. linear or linear-lanceolate:

2753. *Papaver orientale*, the most popular perennial poppy.

scapes single or several, the bud ovoid or round-obovoid, usually pilose, nodding; fls. white, fragrant; petals round-obovate, erose, nearly 1 in. long or less: caps. oblong to obovate, strongly ribbed. Alps, Apennines.—The following garden varieties have been offered as of this species, but some of them are probably *P. pyrenaicum*: *albiflorum*, *album*, *aurantiacum*, *flaviflorum*, *flavum*, *roseum* and *rubrum*. *P. luteum*, Hort., belongs here, but *P. luteum* of the botanists is the Welsh poppy, *Meconopsis cambrica*.

DD. Scapes longer, particularly in cult.

20. *nudicaule*, Linn. ICELAND POPPY. Fig. 2754. Mostly a yellow-fl. arctic perennial, more robust than the two preceding, caespitose, nearly stemless: lvs. all radical and petiolate, somewhat glaucous, glabrous or hairy, pinnatifid, the segms. oblong and entire or lobed: scapes single or several, usually 1 ft. high, the bud ovoid or nearly globose, pilose, usually nodding; fls. 1-2 in. diam., sweet-scented; petals obovate and sinuate, white with yellow base or yellow with greenish base, the 2 inner ones smaller: caps. oblong or obovate-glo-

bose, hispid or rarely glabrous. Arctic regions. E. and W. hemispheres.—The species runs into very many botanical forms. In America a form or similar species is found as far south as S. Colo. Gn. 26:380; 24, p. 342; 28, p. 58; 42, p. 584; 79, p. 42. G. 6:321; 7:66. V. 13:297. B.M. 1633; 3035, and R.H. 1890:60 (*P. croceum*). F. S. 10:1017 (as var. *croceum*). The following varieties are in the trade: *album*, *aurantiacum*, *coccineum*, *croceum*, *striatum*, and *sulphureum*. Double forms in the various colors are advertised. Older names which are likely to appear are vars. *luteum*, *puniceum*, and *rubro-aurantiacum*. B.M. 2344. The name "nudicaule" refers to the lack of lvs. on the scape, which distinguishes this and the alpine poppy from the common corn poppy of Eu. *P. greenlandicum*, Hort., is possibly a catalogue name for *P. nudicaule*. The Iceland poppy is a favorite for spring bloom. It is a hardy perennial, but blooms the first year from seed. It has neat evergreen foliage on the ground.

2754. Iceland poppy, *Papaver nudicaule*. ($\times \frac{1}{2}$)

The colors have been much varied in the cult. sorts, so that the gardener has choices in pure white, bright yellows, orange, and orange-scarlet. If the seed-pods are continuously removed, the plant will bloom throughout most of the summer. The fls. are very useful for cutting.

P. Heldreichii, Hort.=*P. Schinzianum*, below.—*P. heterophyllum*, Greene=*Meconopsis heterophylla*.—*P. Höpkinsii*, Hort. Apparently perennial, and described as a particularly good poppy of medium height with deep scarlet fls. on slender graceful sts. Offered abroad.—*P. Monetti*, Hort. Spontaneous hybrid between *P. glaucum* and *P. Rhoeas*.—*P. pilöse-bracteatum* is a garden hybrid, as indicated in the name.—*P. Schinzianum*, Fedde. Probably a garden hybrid between *P. rupifragum* and a species allied to *P. lateritium*, and which has been cult. as *P. Heldreichii*: fls. brick-red; petals suborbicular-obovate, to $1\frac{1}{4}$ in. long; caps. obovoid-clavate.

WILHELM MILLER.

L. H. B.†

PAPAYA (Fig. 2755). The papaya (*Carica Papaya*) is a well-known edible fruit which has spread from its original home in America throughout the tropical world, and is a favorite fruit in many regions. In Hawaii it is said to rank next to the banana in popularity; in nearly all parts of tropical America it is one of the commonest fruits, while early in the seventeenth century it became known in the Orient and is now grown in India, Ceylon, the Malay Archipelago, and many other regions, as well as in tropical Africa and Australia. The name papaya is considered a corruption of the Carib ababai, which in one form or another has been carried around the world; papaia, papeya and papia are some of the various adaptations which are in use. The English name papaw (or pawpaw) is probably derived from the same source, and is widely used; in the United States it has the disadvantage of confusing this fruit with *Asimina triloba*, which is well known in the central and southeastern states under the same name. The Portuguese name, current in Brazil, is mamão (the tree mamoeiro), a word probably referring to the mammiform apex of the fruit; in the French colonies it is called papaye (the plant papayer); in German colonies papaja and papajabaum, or melonenbaum. Several other names are used in tropical America, notably fruta de bomba in Cuba, lechosa in Porto Rico, melon zapote in parts of Mexico, and tree melon in English-speaking countries.

The papaya—a giant herbaceous plant rather than a tree—grows to a height of 25 or 30 feet, and is often likened to a palm in general appearance, though there is, of course, no botanical relationship. The trunk is commonly unbranched, bearing toward its apex large soft deeply-lobed leaves sometimes 2 feet across, upon stiff hollow petioles 2 feet or more in length. The wood is fleshy, the bark smooth, grayish brown, marked by prominent leaf-scars.

The plant is normally dioecious, and produces its flowers in the uppermost leaf-axils, the staminate ones sessile on pendent racemes 3 feet or more in length, the pistillate ones subsessile and usually solitary or in few-flowered corymbs. The staminate flowers are funnel-shaped, about an inch long, whitish, the corolla five-lobed, with ten stamens in the throat; the pistillate flowers are considerably larger, with five fleshy petals connate toward the base, a large cylindrical or globose superior ovary, and five sessile fan-shaped stigmas.

Beside the typical dioecious form, in which male and female flowers are confined to separate plants, it is not unusual to find various other distributions of the sexes; these have been studied in Hawaii by Higgins and Holt, who describe (Hawaii Agricultural Experiment Station, Bulletin No. 32) a number of different forms, such as the occurrence of staminate flowers with more or less rudimentary stigmas and ovaries which sometimes give rise to small fruits; a hermaphrodite form, which regularly produces perfect flowers and good fruits; and various other combinations of staminate, pistillate and hermaphrodite flowers on the same and different plants. It will thus be seen that the distribution of the sexes in the papaya is very irregular; it has been reported by some authorities, indeed, that severe pruning or injury to the tree sometimes results in a change of sex, but this has been observed only on staminate trees of the dioecious type.

Aside from these variations in the distribution of the

sexes, there are marked differences in the size, shape and quality of the fruits produced by different seedlings of the typical dioecious form, and the papayas of certain regions in the tropics are uniformly superior to those of other regions. In Bahia, Brazil, there are two distinct types, one with small nearly spherical fruits not over 6 inches in diameter, and a very superior type called "mamão da India" which produces fruits 18 inches long, cylindrical in form, and of excellent flavor. With the recent discovery of a method of grafting the papaya, which is fully described under *Carica* (page 663; cf. also Circ. No. 119, Bur. Pl. Ind., U. S. Dept. Agric. 1913), the propagation of superior seedlings has been made possible. In addition, much can be done to improve the quality of the fruit through the selection of seed, but the number of males which arise is usually much greater than is necessary to furnish pollen for the female trees. Through vegetative propagation, it is possible to eliminate all unnecessary males and propagate only a sufficient number to furnish the required pollen—not more than one in ten.

The fruit is commonly spherical or cylindrical in form, round or obscurely five-angled in transverse section, from 3 up to 20 or more inches in length, sometimes weighing twenty pounds or over. In general character it strongly resembles a melon; the skin is thin, smooth on the exterior, orange-yellow to deep orange in color, while the flesh, which is concolorous with the skin, is from 1 to 2 inches thick, and incloses a large sometimes five-angled cavity, to the walls of which are attached the numerous round wrinkled and blackish seeds, the size of small peas, inclosed by a thin gelatinous aril.

The flavor is rather sweet, with a slight musky twang which is sometimes objectionable to the novice, and which varies greatly in amount; the best types are of a bland agreeable taste which is almost sure to be relished, and which makes the papaya one of the most popular breakfast fruits in many tropical countries. In Brazil the flavor is thought to be improved if the fruit is lightly scored when taken from the tree, and then allowed to stand for a day so that the milky juice may run out. While most commonly used, perhaps, as a breakfast fruit, like the muskmelon in northern countries, the papaya can be prepared in numerous ways. In Brazil it is served as a dessert, sliced, with the addition of a little sugar and whipped cream. As a salad, in combination with lettuce, it is excellent. As a crystallized fruit it is good, but it has not very much character. When green it is sometimes boiled and served as a vegetable, much as summer squash is in the North. It can also be made into pickles, preserves, jellies, pies, and sherbets. When used as a breakfast fruit it is cut in halves longitudinally, and after the seeds are removed, served with the addition of lemon juice, salt and pepper, or sugar, according to taste.

In the tropics, papayas are in season during a large part of the year, and the yield is enormous, single trees bearing in the course of their lifetime a hundred or more of their immense fruits. In Florida the season extends from December to June, with occasional fruits ripening at other times. While considered a rather difficult fruit to ship, especially when fully ripe, papayas have been sent from Hawaii to San Francisco and marketed in the cities of the Pacific coast. According to Higgins and Holt, the best method of shipment is to wrap the fruits separately in paper, then encase them in cylinders of corrugated strawboard, and pack them in single-tier crates. They should be picked when they show the first signs of ripeness. Refrigeration during the voyage is important.

The fruit of the papaya, as well as all other parts of the plant, contains a milky juice in which an active principle known as papain is present. This enzyme, which was first separated by Peckholt, greatly resembles animal pepsin in its digestive action, and in recent

years has become an article of commerce. Aside from its value as a remedy in dyspepsia and kindred ailments, it has very recently been utilized for the clarification of beer. Its digestive action has long been recognized in the tropics, as evidenced by the common practice of the natives, who rub the juice over meat to make it tender, or wrap a fowl in papaya leaves and let it stand overnight before cooking it.

The papaya succeeds best in regions with a warm climate and rich loamy but well-drained soil. In south Florida it appears to prefer the richer hammock soils to those of pine-lands, but may be very successfully grown on the latter with proper fertilizing. On the Florida Keys, the plant has become thoroughly naturalized, and springs up wherever a clearing is made, the seeds being scattered by birds and other agencies. It withstands but little frost, although it is occasionally possible to fruit it toward the northern part of the state when a mild winter allows it to reach its second summer without injury. In California, the papaya has never been very successful, probably because the nights are too cool to mature the fruit perfectly. It has been noticed in the tropics that fruit ripened in cool weather is poor and somewhat squash-like in flavor. The best locations in southern California are the protected foothill regions, where the ground is sloping and the soil well drained, and where the heat during the summer months is more intense than on the seacoast. An old tree at Hollywood, Los Angeles, bore fruit for several years, but finally succumbed to the cold rains of winter, which often cause the plants to rot off at the base, especially if the drainage is the least bit defective.

In Hawaii the papaya is said to succeed on almost any soil, provided it is well drained. As soon as the plants are well started they like plenty of moisture, and are rank feeders. On the shallow soils of south Florida, organic nitrogen should be abundantly supplied.

The papaya is easily grown from seed, which in Florida should be planted as early as possible,—preferably in January,—in order to have the plants in fruit by the following winter. If seeds are washed and dried after removal from the fruit, and stored in glass bottles, they will retain their viability for several years. A light sandy loam is a good medium for germination, and the seeds should be sown rather thickly about ½ inch deep. They may be potted off when they have made their third leaves, and from pots later set out in the ground. As the stems of young plants are very succulent, care should be taken to avoid damping-off.

For a permanent orchard, the plants should be set not less than 10 feet apart. The papaya is short-lived, and will not usually remain in profitable bearing more than two to four years. That it is of extremely simple culture is proved by the ease with which it becomes naturalized in tropical regions, and the thriftiness of the wild plants.

2755. Fruit of papaya. ($\times \frac{1}{6}$)

Two pests have become sufficiently troublesome in south Florida to require attention, one of which, the papaya fruit-fly (*Toxotrypana curvicauda*), threatened at one time to become serious (Cf. Journ. Agr. Research, ii. 447-453, Knab & Yothers). This insect occurs in several parts of tropical America; the female inserts her eggs into the immature papaya by means of a long ovipositor, and the larvæ first feed in the central seed-mass, but later work into the flesh of the fruit, frequently rendering it unfit for human consumption. The only means of control which have been suggested are the destruction of wild plants and infested fruits, and the production of varieties of the papaya with very thick flesh, so that the female will be unable to reach the seed cavity with her ovipositor;—the young larvæ are unable to live in the flesh. A fungous disease, known as papaya leaf-spot (*Pucciniopsis caricae*) frequently attacks the foliage during the winter season, forming small black masses on the under surfaces of the leaves. It is not very destructive, and easily controlled by spraying with bordeaux mixture. F. W. POPENOE.

PAPÈDA (Malayan name). *Rutaceæ*, tribe *Citrææ*. Under this name Hasskarl in 1842 created a new genus to include a form closely related to if not identical with *Citrus Hystrix*, DC. A number of species of *Citrus* closely related to *C. Hystrix* have been reported from the Indo-Malayan and western Polynesian regions. As these species are for the most part only imperfectly described, it is doubtful whether they are valid species or forms of one polymorphic species. This group of forms may constitute a subgenus under *Citrus*, distinguished by having very large broad-winged petioles sometimes equaling or even exceeding in area the lamina, small fls. with free stamens, rough frs. with sour and acrid pulp composed of very short pulp-vesicles, containing oil in the center. *Citrus (Papèda) Hystrix*, DC., probably includes *Papèda Rumphii*, Hassk. The forms of this subgenus are sometimes used in the Philippines as stocks on which to graft the commonly cult. species of *Citrus*. The frs. are not edible but are used by the natives of the Malayan and Polynesian islands in lieu of soap for washing the hair.

WALTER T. SWINGLE.

PAPER PLANT: *Cyperus Papyrus* and *Papyrus antiquorum*.

PAPHÍNIA (Paphos, city of Cyprus, sacred to Venus). *Orchidaceæ*. A rare and pretty genus of orchids, having the habit of small lycastes.

Flowers curiously shaped, borne on pendent scapes which are mostly 2-fld.; sepals and petals similar, spreading; mentum obsolete, labellum uppermost in the fl. They may be easily grown with lycastes, and should be planted in fibrous peat and moss. During the growing period they require a liberal supply of water.

cristata, Lindl. (*Lycaste cristata*, Nichols.). Pseudobulbs ovate, 1-3-lyd.; lvs. lanceolate, 4-6 in. long; scapes pendent, 1-2-fld.; sepals and petals lanceolate, acuminate, spreading, the latter a little smaller; all streaked above and transversely banded below with deep crimson or chocolate-brown markings on a whitish ground; labellum much smaller, chocolate-purple; the 2 lateral lobes oblong, pointed, half spreading, separated from the middle lobe by a deep constriction; middle lobe triangular-rhomboid, with an erect crest and clavate glands on the disk, and bordered in front by a fringe of clavate hairs. June-Aug. Trinidad. B.M. 4836. B.R. 1811 (as *Maxillaria cristata*). Gn. 78, p. 33.

rugosa, Reichb. f. Pseudobulbs small, rounded: lvs. small, linear, acuminate; fls. waxy, creamy white, covered with red spots, which run together in blotches. Colombia.

grandiflora, Rodrig. (*P. grandis*, Reichb. f.). Fls. chocolate-brown, striated on the lower half of the sepals and petals with greenish yellow and cream-color, mar-

gins cream; labellum dark purple at the base, with an oblong, cream-colored middle lobe, and a pair of small lobes on each side. Brazil. G.C. III. 14:561.—A curious orchid.

P. Lawrenceana=*Lycaste Lawrenceana* (?).

HEINRICH HASSELBRING.

PAPHIOPEDILUM (from Paphos, *Paphinia* see, and Latin for sandal). *Orchidaceæ*. Terrestrial or epiphytic orchids grown in a warm greenhouse; comprises the glasshouse cyripediums.

Rhizome somewhat creeping; lvs. coriaceous, keeled below, sulcate above, conduplicate in veneration, green or tessellated: fls. showy; sepals 3, the dorsal erect, showy, the lateral united; petals spreading or pendulous; lip saccate, the margin of the orifice not inflexed; column short; ovary 1-celled, with parietal placentæ.—About 50 species in Trop. Asia, Malay Archipelago, Philippines. Differ from *Cypripedium* chiefly in having the lvs. conduplicate in the bud instead of convolute and in having a deciduous perigonium instead of withering and persistent. Cf. Pfitzer, *Pflanzenreich*, hft. 12.

Cultivation of paphiopediums. (Alfred J. Loveless.)

Paphiopediums generally are of easy culture, and may be grown in one house by devoting the cool end to *P. insigne* and its hybrids, and the selenipedium group. The plants should never be allowed to become dry, as they are making active growth most of the time. Light spraying should be frequent in bright weather, and an application of very weak liquid manure occasionally will be found of great assistance in keeping the plants healthy. Ventilation regulated according to external conditions is essential at all times to maintain atmospheric action.

During the winter months the thermometer should register from 55° to 60° F. by night, and about 65° F. by day, with sun heat a few degrees higher doing no harm. On the approach of spring the temperature should be slightly advanced to prepare the plants for summer heat, and accordingly decreased on the approach of fall. A light shading will be necessary at all times, to prevent excessive heat and sunburn, with heavier shading toward midsummer by the addition of bamboo shades, these to be removed in autumn, and dispensed with during the winter.

The greater part of the species grow best in pots, in a compost composed of two parts peat-fiber, one part turfy loam, one part chopped living sphagnum, one-third of the pot room being devoted to clean drainage. The compost should be pressed in rather firmly around the roots, finishing off about ½ inch below the rim of the pot. A sharp lookout should be kept for thrip, and clean pots, with frequent sponging of the foliage, is essential to the good health of the plants. *P. insigne* and kindred species should have one part chopped sod added to the above mixture (see note on culture in Veitch's "Orchid Manual" 2:34). *P. villosum* and *P. Exul* sometimes suffer under pot culture from fungi, which attack the base of the plant in sultry summer weather. Basket culture will obviate this, as it allows a better circulation of air through the compost. *P. Loweii*, *P. Parishii*, *P. philippinense* and allied species, together with *Selenipedium cardatum*, are truly epiphytic and preferably should be grown in baskets. By this method the roots are better preserved and less liable to decay during the winter season.

The concolor section requires a warm moist location with free access to the air. The species should be grown in rather small pots, with at least half the space devoted to drainage of broken charcoal or other free material. The potting compost should consist of equal parts chopped sod, peat-fiber and living sphagnum. Limestone is often recommended as essential in the culture of this section, but, the conditions being equal, it gives no beneficial results (*Orchid Review* 4:45; *Veitch's Manual* 2:19, 20).

LXXXIV. A plantation of papaya in the Hawaiian Islands.

The deciduous tropical species require similar treatment to the evergreen kinds. They have a long dormant period during which they should be rested in a temperature of 50° F., with sufficient water to keep the compost moist until growth starts, when they must be returned to their proper department and enjoy a liberal supply of water until after the flowering season, when they must be ripened off and the water supply gradually withheld.

The hardy species (true *cyripediums*) do better planted out in the open ground or in rockeries, where they should be so situated as to have good drainage and shade. The soil must be free and porous and consist of three parts chopped turf and equal parts of peat and sphagnum. They require a liberal supply of water and frequent syringing over the foliage while growing, but the supply should be gradually reduced after the flowering period until only enough water is given to keep the soil moist. During the winter the plants should be protected with leaves or pine boughs. *Cypripedium reginae* and *C. pubescens* grow well under pot culture. A 7- to 10-inch pot will hold eight or a dozen crowns, which should be planted 2 inches below the surface. Two inches of drainage are sufficient. The pots should be filled with soil (firmly pressed in) to $\frac{1}{2}$ inch below the rim. After a thorough watering they should be stored in a coldframe and protected with leaves and boughs. About the middle of February they may be removed to a coolhouse, where they should remain for a week, and then be placed in the cool end of the *cyripedium* house, where they should be watered sparingly until growth-action starts. These plants make strong growths under this treatment, and the flowers are a decided improvement over those produced outside. See *Cypripedium* and *Phragmopedilum*.

All paphiopedilums are propagated by division, but many beautiful hybrids have been added to the list, since the raising from seed has been better understood.

GENERAL KEY TO SECTIONS.

- A. *Petals broadly elliptic or almost orbicular.* SECTION I. Species 1-4.
AA. *Petals elongated.*
B. *Pouch of lip not eared: lvs. green, strap-shaped.* SECTION II. Species 5-10.
BB. *Pouch of lip eared: lvs. various.* SECTION III. Species 11-42.
SECTION I.
A. *Fls. bell-shaped.*
B. *Lip shorter than the petals.* 1. *bellatulum*
BB. *Lip as long as the petals.* 2. *Godefroyæ*
AA. *Fls. spreading.*
B. *Scape shorter than lvs.* 3. *concolor*
BB. *Scape longer than lvs.* 4. *niveum*

1. *bellatulum*, Pfitz. (*Cypripedium bellatulum*, Reichb. f.). Lvs. oblong-elliptic, up to 10 in. long and $3\frac{1}{2}$ in. broad, the upper surface deep green mottled with paler green, the lower surface dull purple: scape shorter than lvs., 1-fld., purple, pubescent; fls. pale yellow or white, spotted with brown-purple; dorsal sepal orbicular, concave, ciliate; petals broadly oval; lip with fewer and smaller spots than the sepals and petals. Summer. Shan States, China. G.C. III. 21:321. J.H. III. 30:513; 43:49. A.F. 6:557; 13:77, 622; 14:675. Gng. 7:129. G. 34:399. G.M. 55:593. O. 1912, p. 19. L. 4:149. C.O. 9. Var. *album*, Rolfe. Fls. white, the lvs. not colored beneath. C.O. 9a. Var. *Chotekæ*, Hort. The larger fls. with larger spots. L. 665. Var. *egregium*, Hort. Sepal short, 3-lobed, the spots light purple. Var. *luteo-purpureum*, Pfitz. Fls. pale yellow, purple-spotted. Other minor varieties are: *biflorum*, *giganteum*, *grande*, *grandiflorum*, *lineatum*, *Löwii*, *majus*, *roseum*, *superbum*.

2. *Godefroyæ*, Pfitz. (*Cypripedium Godefroyæ*, Rolfe. C. *concolor Godefroyæ*, Hemsl.). Lvs. up to 6 in. long and $1\frac{1}{4}$ in. wide, deep green, marbled and spotted with paler green on the upper surface, the lower surface spotted with brown-purple: scape shorter than lvs., pubescent, green, purple-spotted, 1- or 2-fld.; fls. white or pale yellow, lightly pubescent, spotted magenta; dorsal sepal nearly orbicular; petals oblong-elliptic, deflexed; lip with the spots very small. Summer. Cochin-China. B.M. 6876. G.W. 14, p. 367. G.Z. 31:169. Gn. 25, p. 396. G.C. II. 23:49. Var. *Laingii*, Pfitz. Fls. smaller, white with purple dots. Var. *leucochilum*, Pfitz. Fls. white, the sepals and petals purple-spotted. Var. *Mariæ*, Pfitz. Fls. large, the white petals with black-purple spots. Other minor varieties are: *ampliatum*, *hemi-xanthinum*, *Smithiæ*, *striatum*, *superbum*, *viridifolium*.

3. *concolor*, Pfitz. (*Cypripedium concolor*, Batem.). Lvs. up to 6 in. long and $1\frac{1}{2}$ in. wide, oblong-oval, deep

green, mottled above with grayish green, below spotted with deep crimson: scape shorter than lvs., 1- or 2-fld.; fls. pale yellow, dotted with purple; sepals and petals ciliolate; dorsal sepal nearly orbicular; petals broadly oblong-elliptic, deflexed; lip small, nearly cylindric, somewhat laterally compressed. Autumn. Moulmein. B.M. 5513. G.C. 1865:626; II. 19:19; III. 9:501. I.H. 12:444. F.S. 22:2321. G.Z. 30:97. Var. *chlorophyllum*, Pfitz. Lvs. concolored, not mottled: fls. with numerous dots. Var. *longipetalum*, Pfitz. Petals obovate, narrower than and almost twice as long as sepals. Var. *Requièrei*, Pfitz. Larger, with sepals violet-spotted externally. Var. *sulphurinum*, Pfitz. Fls. sulfur-colored: lvs. green. Var. *tonkinense*, Pfitz. (*C. tonkinense*, Godefr.). Sepals and petals larger. L. 77.

4. *niveum*, Pfitz. (*Cypripedium niveum*, Reichb. f.). Lvs. up to 6 in. long and $1\frac{1}{2}$ in. broad, dull dark green above, spotted gray-green, lurid purple beneath: scape equaling or longer than lvs., 1- or 2-fld.; fls. white; sepals and petals ciliolate; dorsal sepal orbicular, concave, reddish purple on the back; purple-dotted in front toward the base; petals broadly oblong or nearly orbicular, a little deflexed; lip shorter than sepals and petals. Spring. Loncavi and Tambilan Isls. B.M. 5922. G.Z. 19:17. J.H. III. 45:559. Var. *album*, Pfitz. Fls. pure white. Var. *punctatum*, Pfitz. Base of petals densely violet-dotted. Var. *reticulatum*, Pfitz. Petals purple-reticulated at the apex, the nerves purple-spotted. Other minor varieties are: *punctatissimum*, *Requièrei*, *roseum*.

SECTION II.

- A. Sepals with simple nerves, no cross-nerves.
 B. Length of petals flat, ciliate..... 5. Rothschildianum
 BB. Length of petals twisted, the margins with hair-bearing warts.
 C. Length of petals 6 in. or less.
 D. Staminiodium pointed in front.
 E. Point a long beak..... 6. glanduliferum
 EE. Point short..... 7. præstans
 DD. Staminiodium notched in front... 8. philippinense
 CC. Length of petals over 1 ft. 9. Sanderianum
 AA. Sepals with the nerves united by slender cross-nerves, hence reticulated. 10. Stonei

5. *Rothschildianum*, Pfitz. (*Cypripedium Rothschildianum*, Reichb. f. *C. neo-guineense*, Lind.). Fig. 2756. Lvs. up to 2 ft. long and 3 in. wide, glossy green: scape erect, a little exceeding the lvs., violet, minutely pubescent, the bract yellowish green, ciliate, lined with black-purple; fls. about 5 in. in long diam.; dorsal sepal ovate, acute, ciliolate, about 15-nerved, yellow, lined with black-purple; petals about 5 in. long, twice larger than sepals, linear, 7-nerved, undulate, pale green, purple-spotted; lip about as long as sepals, lateral somewhat compressed, dull purple, the apex yellow. Winter. Borneo and Sumatra. R. 2:61. B.M. 7102. V.O. 4:45. G.F. 6:145. A.G. 21:91. G.C. III. 27:137. Gt. 51, pp. 486, 487. J.H. III. 60:3. R.B. 24:221. Var. *Elliottianum*, Pfitz. (*Cypripedium Elliottianum*, O'Brien). Fls. ivory-white, red-lined; petals shorter; staminiodium acutely 2-toothed at apex. Philippines. L. 4:186. J.H. III. 32:55. A.F. 6:557; 7:855. Var. *platytanum*, Hort. Sepals and petals longer and broader than in the type. L. 623.

6. *glanduliferum*, Pfitz. (*Cypripedium glanduliferum*, Blume. *C. præstans*, Veitch, not Reichb. f.). Lvs. strap-shaped, up to 8 in. long and nearly 1 in. wide: scape dull purple, 1-fld., scarcely exceeding lvs., or several-fld. and exceeding the lvs.; fls. green and rose; dorsal sepal narrowly ovate, acute, about 13-nerved, nearly $1\frac{1}{2}$ in. long; petals about $2\frac{1}{4}$ in. long, deflexed, lanceolate and long-attenuate from a rhomboid base, twisted, the undulate margins with hair-bearing warts; lip about equaling the petals, the broad claw about half the length of lip, the basal lobes very narrow, involute,

the sac very short and confined to apex of lip. Summer. New Guinea.

7. *præstans*, Pfitz. (*Cypripedium præstans*, Reichb. f. *C. glanduliferum*, Veitch, not Blume). Lvs. strap-shaped, up to 1 ft. long and $2\frac{1}{4}$ in. wide: scape about equaling lvs., black-purple, pubescent, several-fld.; dorsal sepal oblong, acute, about 15-nerved, whitish, purple-lined, yellowish on back, about 2 in. long; petals yellow, about 5 in. long, twisted, cuneate-elliptic and long-attenuate from a narrow base, the undulate margins with hair-bearing warts; lip a little longer than the sepals, shining, yellow suffused red, the sac laterally compressed conic. Aug. New Guinea. L. 3:102. I.H. 34:26. Var. *Kimballianum*, Hort. (*Cypripedium præstans* var. *Kimballianum*, Hort.). Lines on the sepals broader; petals broader at base, densely red-lined, the warts larger; lip white, rose-suffused. New Guinea. L. 249.

8. *philippinense*, Pfitz. (*Cypripedium philippinense*, Reichb. f. *C. lævigatum*, Batem.). Lvs. oblong-lig-

2756. *Paphiopedilum Rothschildianum*.
($\times 4$)

late, up to 1 ft. long, glossy: scape up to $1\frac{1}{2}$ ft. tall, 3-5-fld.; fls. 3 in. largest diam.; dorsal sepal broadly ovate, acute, whitish, striped purple-brown; petals linear, twisted, 5-6 in. long, ciliate, with small hair-bearing basal warts, yellowish at base, passing into dull purple, the apex pale green; lip buff-yellow, lined faintly with brown. April and May. Philippines. B.M. 5508. G.C. 1865:914. F.M. 298. B.H. 1867:6. F.S. 17:1760, 1761. G.F. 3:309. Var. *platytanum*, Desb. Petals a little longer and twice broader than in type. Var. *Cannærtianum*, Pfitz. (*Cypripedium Cannærtianum*, Lind. *C. Roebbelenii* var. *Cannærtianum*, Pucci). Lateral sepals not united as in type.

9. *Sanderianum*, Pfitz. (*Cypripedium Sanderianum*, Reichb. f.). Lvs. up to 1 ft. long: scape barely as long as lvs., purple, pubescent, several-fld.; fls. about 4 in. largest diam.; dorsal sepals broadly lanceolate, concave, acute, ciliolate, pale yellowish green with broad brown lines, pubescent on back; petals linear, twisted, $1\frac{1}{2}$ ft. long or more, ciliate at the broader base, pale yellow margined with brown-purple at base, above this spotted with brown-purple, the remainder, the greater part, dull purple barred or spotted here and there with pale

yellow; lip brown-purple above, pale yellow beneath. Feb.-May. Malay Archipelago. G.C. III. 19:329. Gt. 43, p. 520. R. 1:3.

10. *Stönei*, Pfitz. (*Cypripedium Stönei*, Hook.). Lvs. up to 1½ ft. long; scape up to 2 ft. tall, greenish purple, pubescent, 3-5-fld.; fls. about 4 in. greatest diam.; dorsal sepal cordate, acuminate, white, with usually 2 or 3 dark crimson streaks; petals 5-6 in. long, linear, twisted, sparsely ciliate at base, the lower two-thirds pale tawny yellow, crimson-spotted, the remainder crimson; lip dull rose, veined and reticulated with crimson, the narrow infolded lobes whitish; staminodium fringed except in front. Autumn. Borneo. B.M. 5349. I.H. 10:355. F.S. 17:1792, 1793. L. 6:281. Var. *acrosèpalum*, Reichb. f. Dorsal sepal narrower than in type, the lateral sepals free. Var. *Cannærtianum*, Hort. Dorsal sepal white; petals longer than in the type, creamy white with a central line of chocolate spots. Var. *platytænium*, Reichb. f. Fls. larger, the petals much broader, white, spotted with yellow and purple, the apex carmine. G.C. 1867:1118. F.M. 1880:414.

SECTION III.

- A. Scape several-fld.
 B. Fls. all appearing at same time: lvs. nearly erect.
 C. Petals with hairy warts, narrow, pendent, much twisted.....11. *Parishii*
 CC. Petals without warts, dilated at apex, divaricate.
 D. *Staminodium* cordate, with a tooth in the sinus; apex of petals 4 times broader than lower half.....12. *Loweii*
 DD. *Staminodium* oval, 2-lobed; petals but little broader at apex.....13. *Haynaldianum*
 BB. Fls. appearing in succession: lvs. recurved.
 C. Lvs. green, more or less netted.
 D. Pouch long and narrow.....14. *Victoria-Mariæ*
 DD. Pouch short and broad.....15. *Chamberlainianum*
 CC. Lvs. glaucous, not netted.....16. *glaucophyllum*
 AA. Scape 1-, very rarely 2-, fld.
 B. Lvs. not netted or reticulated: sepals always netted.
 C. *Staminodium* not lunate.
 D. The *staminodium* with 3 protuberances.....17. *hirsutissimum*
 DD. The *staminodium* with 1 protuberance.
 E. Margins of *staminodium* flat; * petals flat or but slightly undulate on margins.
 F. Petals dilated; *staminodium* obcordate.
 G. Ovary white-villous; petals much dilated, the upper part almost orbicular.....18. *villosum*
 GG. Ovary purple hairy.
 H. *Staminodium* pilose above.
 I. Dorsal sepal much larger than lower sepals.....19. *insigne*
 II. Dorsal sepal about as long as lower sepals.....20. *exul*
 HH. *Staminodium* glabrous.....21. *Charlesworthii*
 FF. Petals elliptic; *staminodium* cordate.....22. *Druryi*
 EE. Margin, the posterior, of *staminodium* revolute; petals strongly undulate on margin.....23. *Spicerianum*
 CC. *Staminodium* lunate.....24. *Fairieanum*
 BB. Lvs. netted or reticulated.
 C. Petals manifestly dilated above. [anum]
 D. *Staminodium* umbonate.....25. *Appletoni-*

- DD. *Staminodium* not umbonate.
 E. Lvs. pale beneath, shorter than scape.
 F. Sepals not reticulated.
 G. Petals, the upper margin with warts; *staminodium* nearly rhomboid.....26. *Bullenianum*
 GG. Petals without warts.....27. *Volonteanum*
 FF. Sepals manifestly reticulated.....28. *Hookeræ*
 EE. Lvs. violet-marbled beneath, about as long as scape.....29. *venustum*
 CC. Petals not or but little dilated above.
 D. Margin of petals naked or ciliate, but without spots or warts.
 E. Sepal-nerves numerous, close.
 F. Front of lunate *staminodium* 2-lobed.
 G. Petals with upper margin naked.....30. *tonsum*
 GG. Petals ciliate on both margins.
 H. Dorsal sepal obtuse.....31. *Mastersianum*
 HH. Dorsal sepal acute or acuminate.
 I. Sinus of *staminodium* not 3-toothed; dorsal sepal ovate, acute.....32. *virens*
 II. Sinus of *staminodium* 3-toothed; dorsal sepal nearly orbicular, long-acuminate.....33. *javanicum*
 FF. Front of *staminodium* not 2-lobed, nearly orbicular.....34. *Dayanum*
 EE. Sepal-nerves few, distant.....35. *purpuratum*
 DD. Margin of petals with spots or warts bearing tufts of hairs.
 E. Petals somewhat falcate or deflexed, their upper surface marked with numerous spots or warts.
 F. Margin of petals with numerous approximate warts or spots.
 G. Lip longer than the petals, obliquely descending.....36. *Curtisii*
 GG. Lip equaling or shorter than the petals, directly descending.
 H. Claw of the lip less than half as long as the sac.....37. *ciliolare*
 HH. Claw of the lip half as long as the sac.....38. *superbiens*
 FF. Margin of petals with few large warts.....39. *Argus*
 EE. Petals sigmoid, or curved in two directions, their upper surface spotless or with few spots.
 F. Upper margin of petals only with warts.
 G. Lower sepal elliptic-ovate, obtuse; lobes of lip with small warts.....40. *barbatum*
 GG. Lower sepal narrowly ovate, acute; lobes of lip with large warts.....41. *callosum*
 FF. Upper and lower margins of petals with warts.....42. *Lawrenceanum*
 11. *Párishii*, Pfitz. (*Cypripedium Párishii*, Reichb. f.). Lvs. oblong-ligulate, up to 16 in. long and 2½ in. wide, bright green: scape 4-8-fld., pale green, downy; fls. about 3 in. across; dorsal sepal oblong-elliptic, pale yellow, green-veined, the upper part bent forward, the basal lateral margins revolute; petals twisted, linear, 4-6 in. long, pendulous, the basal part green, with few blackish dots, the upper half blackish purple, pale-margined; lip deep green, often stained brown-purple;

staminodium pale yellow, green-mottled, obovate-oblong. Autumn. Moulmein. B.M. 5791. Gt. 47, p. 25. I.H. 22:214.

12. *Lôwei*, Pfitz. (*Cypripedium Lôwei*, Lindl.). Lvs. ligulate, up to 15 in. long; scape much exceeding lvs., nodding, 3-6-fld.; fls. 3-4 in. diam.; dorsal sepal oval, acute, yellowish green, veined with purplish brown at base, pubescent at the back; petals spatulate, twisted, about 3 in. long, deflexed, the basal part yellow, black-spotted, the upper part violet-purple; lip brown, paler beneath; staminodium obcordate, the border with purple hairs, a small erect hairy horn at the base. April and May. Borneo. F.S. 4:375. A.F. 11:1349. R.H. 1857, p. 402; 1883, p. 352; 1885, p. 473. Var. *cruciforme*, Hall. (*Cypripedium cruciforme*, Zoll. & Morr.). More slender, with narrower paler lvs. which are often obscurely marbled. W. Java.

13. *Haynaldianum*, Pfitz. (*Cypripedium Haynaldianum*, Reichb. f.). Lvs. up to 16 in. long and 2 in. broad: scape much exceeding lvs., long-hairy, 4-6-fld.; fls. 4 in. greatest diam.; dorsal sepal oval, obtuse, whitish tinted with rose above, the lower half with revolute margins pale yellowish green, with large brown spots; petals spatulate-linear, 3-4 in. long, twisted and recurved above, ciliate, yellowish green below with large brown spots, the upper half pale dull purple; lip pale green, tinged with dull purple; staminodium oblong, 2-lobed in front. Jan.-May. Philippine Isls. B.M. 6296.

14. *Victória-Mariæ*, Rolfe (*Cypripedium Victória-Mariæ*, Rolfe). Lvs. broadly linear-oblong, paler beneath: scape several-fld., much exceeding lvs., brown, pubescent; fls. about 4 in. greatest diam.; dorsal sepal nearly orbicular, concave, the margin reflexed, white-ciliate; petals about $1\frac{1}{4}$ in. long, spreading, linear-lanceolate, twisted, white-ciliate, green, red-margined; lip about as long as petals, purple, green-margined; staminodium rhomboid-ovate. Sumatra. B.M. 7573.

15. *Chamberlainianum*, Pfitz. (*Cypripedium Chamberlainianum*, O'Brien). Lvs. up to 1 ft. long and $1\frac{1}{2}$ in. wide, narrowly white-margined: scape much exceeding lvs., several-fld., grayish brown, densely pilose, nodding; fls. about 4 in. greatest diam.; dorsal sepal almost orbicular, emarginate, the basal margin reflexed, white-ciliate, green, suffused with brown at base, the curved nerves brown; petals about $1\frac{1}{4}$ in. long, linear, spreading, twisted, long-ciliate, green, marked with small purple spots in lines along the nerves; lip about as long as sepals, pale green, with many violet dots. Sumatra. B.M. 7578. R.H. 1892, pp. 104, 105. G.F. 5:413. Gn.W. 8:641. G.W. 6, p. 471. R.B. 26:253.

16. *glaucochyllum*, J. J. Smith. Lvs. glaucous, broadly strap-shaped: scape many-fld.; dorsal sepal orbicular-ovate; petals linear, twisted, ciliate, red-dotted; lip large, violet; staminodium large, ovate, black-violet. Java. B.M. 8084.

17. *hirsutissimum*, Pfitz. (*Cypripedium hirsutissimum*, Lindl.). Lvs. narrowly strap-shaped, up to 6 in. long and $\frac{3}{4}$ in. wide, indistinctly marbled: scape shorter than the lvs., black-purple, hirsute, 1-fld.; fls. 4-5 in. greatest diam.; dorsal sepal nearly orbicular, the base and central part marked with blackish purple, often confluent dots, the remainder green; petals about 3 in. long, broadly spatulate, spreading, somewhat twisted, the margin undulate, the base marked with deep purple on a green ground and studded with many black hairs, the upper bright violet-purple; lip dull green, purple-stained and with minute blackish warts; staminodium almost square, with 3 protuberances and 2 white eyes. March-May. Assam. B.M. 4990. J.H. III. 52:513. R.H. 1859, pp. 182, 183. I.H. 4, p. 67 (note). F.S. 14:1430.

18. *villosum*, Pfitz. (*Cypripedium villosum*, Lindl.). Lvs. up to 18 in. long and $1\frac{1}{2}$ in. broad, grass-green,

with the lower surface paler and purple-spotted toward the base: scape nearly as long as lvs., 1-fld., hairy; fls. 5-6 in. greatest diam., glossy, the sepals and petals ciliate; dorsal sepal broadly oval, green, the base and center marked with brown-purple, the margin with a narrow white band, the basal margins revolute; petals about 3 in. long, strongly dilated above, yellow-brown, undulate, purple-hairy at the base, the midvein brown-purple; lip brownish yellow, the broad infolded lobes tawny yellow; staminodium tawny yellow, oblong-cordate. Jan., Feb. Moulmein. I.H. 4:126. A.F. 6:555. Gn. 65, p. 435. Var. *Bóxallii*, Veitch (*Cypripedium Bóxallii*, Reichb. f. *P. Bóxallii*, Pfitz.). Dorsal sepal narrower at base, the central part marked with numerous, often confluent, black spots, the marginal band broader. Moulmein. I.H. 26:345. G.W. 5, p. 545. Gng. 15:306. Other varieties are: var. *álbo-marginatum*, Pfitz., the white margin of dorsal sepal broader; var. *atrátum*, Pfitz. (also known as var. *Bóxallii atrátum*), has the dorsal sepal strongly marked with black spots and the white border broad, the petals yellow-brown above, spotted below, and yellow-margined (R. II. 1:8); var. *aureum*, Pfitz., dorsal sepal lemon-yellow, strongly black-spotted, the petals above red-lined; var. *canariense*, Pfitz., fls. with a general yellow tinge; var. *gigantæum*, Pfitz., in color much like var. *aureum*, the petals and dorsal sepals larger; var. *Górtónii*, Pfitz., dorsal sepal with a narrow purple band, bright emerald, the petals pale rose-purple narrowly bordered with greenish black; var. *Lindenii*, Pfitz., fls. larger and more brilliant; var. *Measuresianum*, Pfitz., in color resembling var. *atrátum*, the dorsal sepal yellowish green with a purple base, the lip pale cream; var. *Moënsii*, Pfitz., dorsal sepal black for two-thirds its height, then olive-green bordered with pale cream, the petals reticulated, the staminodium large, the protuberance amethyst.

19. *insigne*, Pfitz. (*Cypripedium insigne*, Wall.). Lvs. linear, up to 1 ft. long and $\frac{3}{4}$ in. broad, pale green: scape usually shorter than lvs., 1-, rarely 2-fld., densely purple-pubescent; fls. 4-5 in. greatest diam., glossy; dorsal sepal broadly oval, with margins somewhat revolute, the base and central portion apple-green, marked with numerous brown-purple spots along the green veins, the upper part white; petals linear-oblong, spreading, undulate, pale yellow-green veined brown-purple; lip yellowish green, brown-shaded; staminodium nearly quadrate, pubescent, the tubercle orange-yellow. Winter. Nepal to Assam. B.M. 3412. G.C. III. 18:763. A.F. 7:633. F.E. 9:327. Gng. 1:243. A.G. 16:73; 19:825. J.H. III. 42:47. C.L.A. 11:43. Gn. 65, p. 101; 72, p. 40.—Extremely variable in coloration, the following being some of the prominent varieties. Var. *álbens*, Pfitz. Fls. soft greenish yellow, with the dorsal sepal pure white in upper half. Var. *álbo-marginatum*, Pfitz. Fls. yellowish; dorsal sepal white-bordered on entire margin, the light-colored spots only on the green portion. Nepal. Var. *Amesianum*, Pfitz. Fls. rather large, not spotted, resembling those of var. *Maulei*; dorsal sepal with a broad white margin, the green part suffused with brown. Var. *amënum*, Pfitz. Dorsal sepal olive-green, marked with large brown spots, and widely bordered with white, with violet spots in the lower part of the border; petals olive-green, suffused with brown; lip clear maroon-brown. Khasia. Var. *apiculatum*, Hort. Var. *Arnoldianum*, Pfitz. Fls. larger than in var. *Maulei*; dorsal sepal greenish yellow, broadly white-margined, the spots confined to the green part. G.F. 7:425. A.F. 6:115. Var. *aureum*, Pfitz. Dorsal sepal yellow below; petals and lip clear yellow-brown. Var. *Breevesianum*, Hort. Dorsal sepal oblong, the lower two-thirds yellowish green, with brown dots in regular lines, the remainder white; petals reddish brown. Var. *Bröwnii*, Pfitz. Fls. large, pale green; dorsal sepal strongly marked with large pustules, each with a white dent at the apex; petals spotted. A.F. 7:65. Var. *brugense*, Hort. Var. *Chántinii*, Pfitz. One of the best

varieties; dorsal sepal large, olive-green below heavily spotted with brown, the upper part only white with a few large mauve spots; lip mahogany, polished. Nepal. R.H. 1878:130. G. 25:60. Var. *citrinum*, Pfitz. Fls. clear citron-yellow, except dorsal sepal, which is clear green at base, bordered with white and some clear mauve spots. Var. *corrugatum*, Pfitz. Lip corrugated. Var. *Colsonianum*, Pfitz. Fl. large, with a broad dorsal sepal. Var. *Cowperianum*. Fls. greenish yellow; dorsal sepal like that of var. *albo-marginatum*, spotted at base; petals larger; lip large. Var. *Cuhingianum*, Pfitz. Fls. large, clear green; dorsal sepal broad, the upper part white, with numerous clear violet spots. Var. *Dormanianum*, Hort. Var. *Dorothy*. Fls. yellow, in form like those of var. *Chantini*. Var. *Dowminianum*, Hort. Var. *Ernestii*, Pfitz. In form and color resembling var. *Sanderæ*, but the spots on dorsal sepal more distinctly defined. Var. *Eyermannii*, Hort. Resembles var. *Sanderæ*: fls. clear greenish yellow, the dorsal sepal with a few indistinct small spots, the upper part white. Var. *Eyermannianum*=var. *Eyermannii*. Var. *Förstermanii*, Pfitz. Dorsal sepal with a broad white border; petals distinctly brown-veined. Nepal. Var. *fuscatum*, Pfitz. R.B. 20:25. Var. *Gilmoreanum*, Pfitz. Fls. large, resembling those of var. *Chantini*; dorsal sepal very broad, bordered white, with large brown spots in the center and smaller ones toward the border. Var. *gracile*, Pfitz. Dorsal sepal narrow, yellowish green, irregularly brown-spotted, white border broad. Var. *Gravesianum*, Pfitz. Fls. on a long peduncle; dorsal sepal with a broad white border and numerous brown spots arranged in regular lines. Var. *guttatum*, Hort. R.H. 1851:201. Var. *Hallianum*, Pfitz. Sepals longer and broader than usual. Var. *Harefield Hall*, Hort. A fine variety, with large fls.; dorsal sepal large and round, with a broad white margin and large bright brown spots. Var. *Horsmanianum*, Pfitz. Dorsal sepal cuneate-oblong, with the entire upper portion white. Var. *Hurrellianum*, Hort. Dorsal sepal greenish yellow, the basal half suffused with reddish brown, the apex white. Var. *illustre*, Pfitz. Fls. yellowish, the sepals and petals spotted. Var. *Kimballianum*, Pfitz. Sepal more than 3 times longer than broad, flat, yellowish green, the spots running in lines into the white border; petals strongly veined. Khasia. Var. *Lageræ*, Hort. Dorsal sepal with a dark brown center, slightly suffused at edges with greenish yellow, with 4 or 5 pink marks, the whole margined with pure white. Var. *Laura Kimball*, Hort. Fls. resembling those of var. *Sanderæ*, but of a chamois-yellow, with a few brown hairs at the base of the petals. Var. *longispalum*, Pfitz. Dorsal sepal very long and narrow, appearing narrower on account of its reflexed margins, pale green slightly tinted and veined brown at base, spotless, with a small white apex. Var. *Lucianii*, Pfitz. Fls. bright yellow, tinted green, dorsal sepal clear green at base, with only 2 or 3 large dots of bronzy yellow, white border very broad. Var. *luteo-album*, Hort. Upper two-thirds of dorsal sepal pure white, remainder yellowish green with few spots. Var. *Lutchwyche-*

Paphiopedilum
insigne var.
Sanderæ. (X 1/2)

anum, Pfitz. Dorsal sepal narrower basal margins wavy, the upper white passing into pale yellow, spots hardly visible. Var. *Macfarlanei*, Pfitz. Fls. clear yellow; dorsal sepal with a broad white border, but without the usual pustules. Var. *Mandevilleanum*, Pfitz. Resembles var. *albo-marginatum*: petals with numerous spots in regular lines. Var. *Maulei*, Pfitz. Dorsal sepal with the white predominant, extending to the base on either side of the green center, the upper spots violet-purple, the others larger and brownish. Nepal. G.W. 6, p. 470. Var. *maximum*, Pfitz. Dorsal sepal deep green, large. Var. *montanum*, Pfitz. Dorsal sepal with a narrow yellow line, the lower three-fourths of a golden yellow, with a brownish tinge due to the large spots; petals yellow, striated with brown-red. Var. *Mooreanum*, Pfitz. Fls. pale yellow, petals pale greenish yellow; dorsal sepal broad-ovate, with a broad white margin; central spots largest, smaller toward the margin; petals brown-veined. Nepal. Var. *Nilonii*, Pfitz. Lip small, round. Var. *punctatissimum*, Hort. Dorsal sepal entirely covered with brown spots except a narrow white margin. Var. *Sanderæ*, Pfitz. Fig. 2757. Lvs. and scape pale: dorsal sepal primrose-yellow with a few minute reddish brown dots, the upper part white; petals yellow; lip waxy yellow. Gng. 7:196. A.G. 21:329. Gt. 56:1559. Var. *Sanderianum*, Pfitz. Fls. yellowish green, reticulated with darker green nerves, the dorsal sepal with a broad white border. Var. *Studbyanum*, Hort. Var. *superbiens*, Hort. Var. *sylhetense*, Pfitz. Dorsal sepal with large dark spots somewhat confluent in lines along the middle.

20. *exul*, Pfitz. (*Cypripedium exul*, O'Brien). Lvs. up to 8 in. long and nearly 1 in. broad, narrowly strap-shaped, lightly marbled, very narrowly white-margined: scape longer than lvs., green, purple-hairy, 1-fld.; fls. about 3 in. greatest diam.; dorsal sepal broadly ovate, obtuse, reticulate-veined, yellowish green with a white margin, brown-spotted; petals longer than the sepals, oblong, a little dilated toward the apex, ciliate, yellow sparsely spotted and lined with brown; lip marked like petals. Siam. C.O. pl. 13. B.M. 7510.

21. *Charlesworthii*, Pfitz. (*Cypripedium Charlesworthii*, Rolfe). Lvs. spotted, up to 10 in. long and 1 in. broad: scape 1-fld., about as long as lvs., purple-spotted, pubescent; fls. about 3 in. greatest diam.; dorsal sepal broadly ovate, large, about 2½ in. long, obtuse, nearly flat, white, mottled and suffused with pale carmine or purple-rose; petals horizontally spreading, a little shorter than sepal, oblong, obtuse, long-hairy at base on inner surface, sparsely ciliate, yellowish green, striated or reticulated with brown. Autumn. Bengal. B.M. 7416. R.B. 20:241. Gn. 47:252. A.F. 13:430. J.H. III. 45:469. O.R. 1:335. L. 10:443. A.G. 25:561.—Variable. The following varieties are known: Var. *conchiflorum*, Pfitz. Dorsal sepal concave. Var. *Crashawæ*, Pfitz. (*Cypripedium Crashawæ*, O'Brien) Has the fleshy lvs. glaucous beneath, the fls. larger. Var. *Desmetianum*, Pfitz. Dorsal sepal with the rose-veined white center surrounded by a band of rose-magenta, and with a white border. Var. *Duvivierianum*, Pfitz. Dorsal sepal orbicular, nearly 3 in. diam., pure white at the base, the radiating nerves of a rose-lilac, the mahogany petals tessellated with amber, the staminodium white with a chrome-yellow umbo. Var. *magnificum*, Pfitz. Fls. very large and brilliantly colored. Var. *marginatum*, Pfitz. Dorsal sepal is white with the base and border rose. Var. *unicolor*, Pfitz. Lip the same color as sepals and petals.

22. *Druryi*, Pfitz. (*Cypripedium Druryi*, Bedd.). Lvs. ligulate, up to 8 in. long and 1¼ in. wide, lightly marbled: scape longer than lvs., purple-hairy, 1-fld.; fls. about 3 in. greatest diam.; dorsal sepal about 1¼ in. long, rhombic-ovate, obtuse, nearly flat, glandular-black-hairy on the back, white-ciliate, yellowish green or citron-color, marked black-purple in center; petals

longer than sepals, narrowly elliptic, obtuse, somewhat falcate, pubescent on back, the face manifestly hairy at base, golden yellow, purple-lined down middle and brown-dotted at the base; lip about as long as petals, yellow. May, June. Travancore. I. H. 24:265. A.F. 6:555. F.M. 1880:425. L. 6. O. 1914, p. 139.

23. *Spicerianum*, Pfitz. (*Cypripedium Spicerianum*, Reichb. f.). Lvs. up to 1 ft. long, and 2 in. broad, broadly linear-lanceolate, pale beneath: scape about as long as lvs., glabrous, black-purple, 1-fl.; fls. about 3 in. greatest diam.; dorsal sepal transversely elliptic when spread out, about $1\frac{1}{2}$ in. long, deeply sulcate, the margins strongly retroflexed, giving the sepal the appearance of a spathe, white, a crimson-purple band down the center, and a large green basal blotch speckled with red; petals a little longer than sepal, spreading, deflexed, somewhat falcate, oblong, strongly undulate at margin, pilose at base on inner surface, green, dotted and suffused with brown; lip longer than sepal, the claw green, the pouch violet, pale-green-margined. Oct.-Dec. Assam. B.M. 6490. I.H. 30:473. Gn. 48, p. 304. A.G. 11:159. A.F. 3:226. Gng. 1:242. F.E. 9:329. G.W. 14, p. 73. J.H. III. 44:27.—Quite variable. Among others, are the following varieties: Var. *alboviride*, Pfitz. Differs in absence of median color of the dorsal sepal. Var. *grandiflorum*, Hort. Fls. larger than usual. Var. *leodiense*, Pfitz. Dorsal sepal for upper three-fourths pure white, with tender green at base, the petals green at the very undulate margins, with the center brownish green, the lip bronzy green. Var. *magnificum*, Pfitz. Lower sepal pure white. Var. *Mercatellianum*, Pfitz. Fls. yellowish white marked with purple, green absent. Var. *nānum*, Pfitz. Dorsal sepal without green basal spot. Var. *nigrāscens*, Pfitz. Fls. smaller, lip blackish brown. Var. *rubāscens*, Pfitz. Dorsal sepal pure white on back, strongly tinted with violet-red on face and marked down the center with a purple band, the petals bronzy green, marked with brown dots.

24. *Fairieanum*, Pfitz. (*Cypripedium Fairieanum*, Lindl.). Lvs. up to 6 in. long and 1 in. broad, strap-shaped, light green, paler beneath: scape much exceeding lvs., green, hairy, 1-fl.; fls. about 3 in. greatest diam.; dorsal sepal nearly orbicular, about $1\frac{1}{2}$ in. long, the basal margin somewhat reflexed and undulate, reticulated at the recurved apex, ciliate, pubescent on back, greenish white, striated and reticulated with violet; petals lanceolate, undulate on the ciliate margin, green, striated with violet; lip a little shorter than the sepal, white at base, green at apex. Autumn. Bhotan. G.C. III. 38:168. J.H. III. 51:321. Gn.M. 3:63. B.M. 5024. F.S. 12:1244. O. 1915, p. 15.

25. *Appletonianum*, Rolfe (*Cypripedium Appletonianum*, Gower. *C. Bullenianum* Appletonianum, Rolfe). Lvs. ligulate, indistinctly tessellated: scape much exceeding lvs., slender, velutinous, 1-fl.; fls. about 4 in. greatest diam.; dorsal sepal ovate, shortly acuminate, the margin at apex involute, the basal margin revolute, yellowish green, brown-striated; petals half longer than sepal, horizontally spreading, somewhat rhombic-dilated above, glabrous, the margins at base undulate, the upper margin usually with a few warts, the lower part green, purple-dotted, the upper part rose; lip green, marked with purple. Siam. O.R. 4:17. C.O. 22. Var. *Poyntzianum*, Pfitz. (*Cypripedium Poyntzianum*, O'Brien). Petals pale green, the apex lilac; lip whitish, rose at base, purple-spotted within. Siam.

26. *Bullenianum*, Pfitz. (*Cypripedium Bullenianum*, Reichb. f. *C. Hookeræ Bullenianum*, Veitch). Lvs. up to 8 in. long, about 1 in. wide, tessellated: scape much exceeding lvs., 1-fl., hirsute; fls. about $3\frac{1}{2}$ in. greatest diam.; dorsal sepal ovate, acuminate, the basal margins reflexed, about $1\frac{1}{4}$ in. long, olive-green, shaded with brown; petals deflexed, dilated from a narrowly oblong base, obtuse at apex, ciliate, the upper margin with

hairless violet-brown warts, olive-green at base, rose-violet above; lip green, marked with greenish brown, longer than sepals but shorter than petals, the inflexed lobes with warts. March and April. Borneo. Var. *anophthalmum*, Reichb. f. Petals not spotted; lip green. Var. *oculatum*, Reichb. f. Claw of the lip ochre-color, brown-spotted; lip red-brown, bordered with green.

27. *Volonteanum*, Pfitz. (*Cypripedium Volonteanum*, Sand. *C. Hookeræ Volonteanum*, Rolfe. *P. Hookeræ Volonteanum*, Kerch.). Fig. 2758. Lvs. up to 8 in. long, 2 in. broad, obscurely tessellated above, paler beneath: scape much exceeding lvs., 1-fl., pale brown with white hairs; fls. about 4 in. greatest diam.; dorsal sepal ovate, long-acuminate, ciliate, the basal margins reflexed, yellowish green; petals nearly twice as long as sepals, deflexed, the narrow base undulate, spatulate and somewhat falcate, long-acuminate at apex, minutely toothed, at the base long-ciliate and barbed, green, rose at apex, upper margin with black spots; lip pale green, suffused rose. June, July. Borneo. Var. *giganteum*, Pfitz. A robust form. Var. *Löwei*, Pfitz. Darker.

28. *Hookeræ*, Pfitz. (*Cypripedium Hookeræ*, Reichb. f. *C. barbātum* Hookeræ, Hort.). Lvs. up to 6 in. long, and 2 in. wide, dark green, tessellated: scape 1-fl., much exceeding lvs., purple, pilose; fls. about 4 in. greatest diam.; dorsal sepal ovate, acuminate, pubescent on back, ciliate, yellowish white, marked centrally with green; petals depressed, spatulate, ciliate, the undulate basal part green with blackish spots, the margin purple, the apex purple; lip pale green, suffused with rose, the infolded lobes yellowish brown, purple-spotted. May and June. Borneo. B.M. 5362. F.S. 15:1565.—The following varieties are known: *cæruleāscens*, *luteum*, *majus*, *Measuresianum*, and *superbriens*.

2758. *Paphiopedilum Volonteanum*. ($\times \frac{1}{3}$)

29. *venustum*, Pfitz. (*Cypripedium venustum*, Wall.). Lvs. up to 6 in. long and $1\frac{1}{2}$ in. wide, above dark green blotched with pale grayish green, beneath strongly violet-mottled: scape about as long as lvs., 1-fl., purple, pubescent; fls. about 3 in. greatest diam.; dorsal sepal broadly ovate, acute, white, veined green; petals somewhat spatulate, spreading, ciliate, longer than sepals, barbed at base, the basal part green with blackish warts, the upper portion brownish dull purple; lip pale yellowish green, rose-tinged, reticulated with green, the infolded lobes yellow. Jan.-March. N. India. B.M. 2129. B.R. 788. Var. *Measuresianum*, Pfitz. Fls. white and green, without the brown or red tinge. Var. *pardinum*, Pfitz. (*Cypripedium pardinum*, Reichb. f. *P. pardinum*, Pfitz.). Warts extending over whole upper surface of the petals which are yellow, suffused with copper-color; inflexed lobes of lip with large conic warts. F.M. 51. Var. *spectabile*, Pfitz. Scape shorter than in the type, the petals strongly colored with mahogany at the apex, the middle area brownish, irregularly black-spotted, the lip large, bronzy green, reticulated with clear green.

30. *tónsum*, Pfitz. (*Cypripedium tónsum*, Reichb. f.). Lvs. up to 8 in. long and 2 in. wide, tessellated, usually beneath toward the base with purple: scape longer than lvs., 1-fl., reddish brown, shortly pilose; fls. 4-5 in. greatest diam., shining; dorsal sepal broadly ovate, acute, ciliate, white, green-veined, or the alternate shorter veins sometimes purplish; petals somewhat spatulate, pale green, sometimes stained with dull purple, green-veined, marked with a few black spots;

lip dull green, tinged crimson and brown, the infolded lobes broad, warty. Autumn. Mountains of Sumatra. C.O. *Cypripedium* 6. The following varieties are known: *cypreum*; *superbiens*, with the dorsal sepal white at the extremity marked with clear brown; and *superbum*.

31. *Mastersianum*, Pfitz. (*Cypripedium Mastersianum*, Reichb. f.). Lvs. up to 10 in. long and 2 in. broad, deep green, tessellated: scape longer than lvs., 1-flid., brown-purple-long-hirsute; fls. 3-4 in. greatest diam.; dorsal sepal nearly orbicular, ciliate, bright green, the border yellowish white, green-veined; petals horizontal, ciliate, obtuse, brownish red, the base paler with numerous blackish purple small warts on the upper margin and midvein; lip pale reddish brown, the infolded lobes spotted dull purple on a greenish brown ground. Spring. Amboina. G.C. III. 15:593; 25:274. B. M. 7629. O. 1910, p. 88.

32. *virens*, Pfitz. (*Cypripedium virens*, Reichb. f. *C. javanicum virens*, Veitch. *P. javanicum virens*, Kerch.). Lvs. up to 6 in. long and 2 in. wide, obscurely tessellated above: scape somewhat exceeding lvs., brown, shortly pilose, 1-flid.; fls. 3-4 in. greatest diam.; dorsal sepal ovate, acute, ciliate, the margin reflexed at base, about 1½ in. long, pale green, striated darker green; petals divaricately spreading, longer than dorsal sepal, obtuse, green at base with scattered small, black warts, the apex pale purple; lip about as long as sepal, green suffused with rose, the inflexed lobes with numerous contiguous small warts. N. Borneo.

33. *javanicum*, Pfitz. (*Cypripedium javanicum*, Reinw.). Lvs. up to 7 in. long and 2 in. wide, distinctly tessellated above, pale green beneath: scape longer than lvs., pubescent, 1-flid.; fls. 3-4 in. greatest diam.; dorsal sepal nearly orbicular, long-acuminate, ciliate, margin reflexed below, pale green, striated darker green; petals somewhat deflexed and falcate, oblong, obtuse, ciliate, green, the inner surface with brown small warts; lip green, the inflexed lobes minutely warty. Java. F.S. 7:703. Var. *majus*, Du Buys. Fls. larger and greener. Var. *minus*, Pfitz. Fls. smaller. Var. *superbum*, Hort.

34. *Dayanum*, Pfitz. (*Cypripedium Dayanum*, Reichb. f. *C. spectabile Dayanum*, Lindl. *C. superbiens Dayanum*, Reichb. f.). Lvs. up to 7 in. long and 2 in. wide, distinctly tessellated: scape much longer than lvs., purple, pilose, 1-flid.; fls. 4-6 in. greatest diam.; dorsal sepal broadly ovate, acuminate, ciliate, white, green-veined; petals ligulate, somewhat deflexed, long-ciliate with black hairs, greenish brown at base, rose-purple above; lip brownish purple, green-veined, the infolded lobes with numerous small purple warts. May, June. Borneo. F.S. 15:1527. Var. *Ernestianum*, Pfitz. Petals crimson-veined at base, the apex white and ciliate with purple hairs. Var. *Pétri*, Pfitz. (*Cypripedium Pétri*, Reichb. f.). Dorsal sepal long-triangular acute, the petals somewhat broadened above, the lip more conical. Var. *Smithianum*, Pfitz. Var. *spléndens*, Pfitz. Fls. more brilliant in color. Var. *superbum*, Pfitz., has the petals maroon in the center, lined with green, the lip maroon veined with greenish brown.

35. *purpuratum*, Pfitz. (*Cypripedium purpuratum*, Lindl. *P. sinicum*, Hance). Lvs. up to 5 in. long and 1½ in. wide, distinctly tessellated, paler beneath: scape longer than lvs., 1-flid., purple, hirsute; fls. 3-3½ in. greatest diam.; dorsal sepal nearly orbicular, abruptly acute, folded at the middle, the basal margins revolute, white with a greenish central stain, purple-veined, ciliate; petals spreading, undulate, narrowly elliptic, somewhat falcate, ciliate with mixed longer and shorter hairs, purplish crimson, with purple or green veins, numerous small blackish warts at base; lip brownish purple, deeper veined and reticulated, infolded purple lobes with numerous warts. Autumn. Hong-Kong. B.M. 4901. F.S. 11:1158. C.O. *Cypripedium* 12. Vars. *Kimballianum* and *Seegeri* are known.

36. *Curtisii*, Pfitz. (*Cypripedium Curtisii*, Reichb. f.). Lvs. up to 8 in. long, tessellated above: scape longer than lvs., 1-flid., pubescent; fls. 3-4 in. diam., the segms. ciliate; dorsal sepal broadly ovate, acuminate, grass-green, white-margined, the numerous green veins purple toward the base; petals ligulate, deflexed, the tips recurved, the margin with black hairs and warts, pale purple, white along the midvein, uniformly purple-spotted, green-veined; lip helmet-shaped, brownish purple, the infolded narrow purple lobes with darker warts. May, June. Sumatra. A.F. 6:557. Gng. 1:41. L. 3:140. Var. *amœnum*, Pfitz. Dorsal sepal brown at base with a broad white margin; petals green toward apex. Var. *pallidum*, Pfitz. Fls. more delicately colored; petals almost white at apex, strongly dotted with clear purple; lip pale greenish, lightly tinted pale brown-purple.

37. *ciliolære*, Pfitz. (*Cypripedium ciliolære*, Reichb. f.). Lvs. obtuse, oblong-elliptic, 6-8 in. long, tessellated: scape longer than lvs., 1-flid., hirsute, black-brown; fls. 4 in. greatest diam.; dorsal sepal broadly ovate, acuminate, ciliate, white, purple at the base, green-veined, or the lateral veins sometimes purple; petals deflexed, recurved, ciliate with long black hairs, green toward base with numerous blackish warts, pale purple at apex; lip manifest, helmet-shaped, dull brownish purple, the pale yellow-green infolded lobes with purple warts. April-July. Malay Archipelago and Philippines. I.H. 31:530. G.C. III. 21:348. Var. *Miteaunum*, Pfitz. Dorsal sepal nearly triangular, reddish crimson at base and strongly black-nerved, the border white, lightly tinted rose; petals crimson at base, dotted with blackish brown. L. 3:146. Other varieties are: *Elmireanum*, *grandiflorum*, *magnificum*, *maximum*, *spléndens*, and *spléndidum*.

38. *superbiens*, Pfitz. (*Cypripedium superbiens*, Reichb. f. *C. barbatum* var. *Veitchii*, Linn. *C. barbatum* var. *superbiens*, Morr. *C. Veitchianum*, Hort.). Lvs. up to 8 in. long and 2½ in. broad, oblong-elliptic, tessellated: scape longer than lvs., brown, white-pilose, 1-flid.; fls. about 4 in. greatest diam., the segms. ciliate; dorsal sepal broadly ovate, acute, white, green-striped; petals deflexed, ligulate, white, green-veined, with numerous blackish warts, the marginal ones larger; lip somewhat helmet-shaped, brownish purple, pale green below, the infolded lobes crimson and warty. May-July. Malay Peninsula. I.H. 12:429. F.S. 19:1996. A.F. 7:707. R.H. 1871, p. 596. J.H. III. 50:3. F.W. 1872: 33.—Vars. *Démidoffii* and *Lindenii* are known.

39. *Árgus*, Pfitz. (*Cypripedium Árgus*, Reichb. f. *C. barbatum* var. *Árgus*, Hort. *C. Pücherianum*, Manda). Lvs. acute, up to 8 in. long and 1½ in. wide, tessellated: scape longer than lvs., brown-hairy, 1- or rarely 2-flid.; fls. 2½-3 in. greatest diam.; dorsal sepal broadly ovate, acute, ciliate, white, the base rarely spotted blackish purple, green-veined, or the longer veins sometimes purple; petals undulate, ligulate, deflexed, acute, ciliate, white, the veins pale green, the upper third pale purple, the inner surface with blackish warts; lip dull brownish purple, pale greenish brown beneath, the narrow infolded lobes pale purple, deeper spotted. March, April. Luzon. B.M. 6175. F.M. 1876:220. B.H. 32:241. R. 2:83. C.O. 5. A.F. 3:179. Var. *Boddartii*, Pfitz. Petals narrower and more strongly deflexed. Var. *Lindenii*, Pfitz. Colors brighter; dorsal sepal larger. Var. *Moënsii*, Pfitz. (*Cypripedium Moënsianum*, Hort.). Dorsal sepal very large, pointed, white, green-lined; petals broader, white, green-lined, strongly spotted with blackish crimson, the spots confluent in transverse masses; lip greenish yellow below, maroon above. L. 3:129. Var. *nigricans*, Pfitz. Spots congested and confluent. Var. *nigro-maculatum*, Pfitz. Dorsal sepal white, lightly tinted rose, dotted reddish brown at base; petals green at base, strongly black-spotted; lip maroon above, olive below. Var. *superbum*,

Pfitz. Dorsal sepal round, lightly acuminate, white, strongly veined with shining green, the border here and there spotted with reddish purple; petals white at base, green-lined, and almost entirely black-spotted; lip reticulated. Other varieties known are: *biflorum*, *giganteum*, *grandiflorum*, *Mantini*, *Morrenianum*, *multicolor*, *nigrum*, *purpuratum*, and *tigrinum*.

40. *barbatum*, Pfitz. (*Cypripedium barbatum*, Lindl. *C. purpuratum*, Wight). Lvs. acute, up to 6 in. long, tessellated: scape longer than lvs., black-purple, pubescent, 1- or rarely 2-fl.; fls. $2\frac{1}{2}$ -3 in. greatest diam.; dorsal sepal nearly orbicular, pointed, folded at the mid-vein, white, more or less purple-stained, green at base, the veins prominent, deep purple, the central green at base; petals spreading, somewhat deflexed, oblong-linear, ciliate, the upper margin with small blackish warts, the base brownish green, the apex purple; lip helmet-shaped, deep brownish purple, paler below, the infolded purple lobes deeper-spotted. June, July. Malay Peninsula. B. M. 4234. B. R. 27, p. 53 (desc.). F. S. 3:190. B. H. 33:7. V. O. 4:12. Var. *biflorum*, Pfitz. Scape 2-fl. Var. *caerulescens*, Pfitz. Dorsal sepal white and green in about equal proportions,

2759. *Paphiopedilum Lathamianum*. Hybrid. (See supplementary list.) ($\times\frac{1}{2}$)

the nerves dark green and crimson; petals olive-green, whitish rose at the apex with a few black dots; lip maroon. Var. *Crössii*, Pfitz. (*Cypripedium Crössii*, Hort. *C. barbatum* var. *Warnerianum*, Warn.). Dorsal sepal large, nearly round, the upper half pure white, the center green, striped deep maroon and tinted rose-purple between the nerves; petals strongly reflexed, rose-violet toward the apex which terminates with a white spot; lip clear maroon. B. H. 15:227. Var. *grandiflorum*, Pfitz. Dorsal sepal very large, the apex pure white, lined and veined with rose-purple at base; petals olive-green above, black-spotted, rose-magenta below toward the apex; lip large, deep purple-maroon. Var. *Hendersonii*, Pfitz. Dorsal sepal has a broad white border, the center shaded with violet, and the base lined with tender green; petals undulate, reflexed, the upper surface olive-green, the lower surface light rose heavily shaded green, the extremity with a white point; lip deep maroon. Var. *illustre*, Pfitz. Dorsal sepal round, acuminate, white, green-lined at base, banded with blackish purple, and broadly white-bordered; petals brownish green above, rose-salmon, below; lip very large, blackish brown. Var. *majus*, Pfitz. Resembles var. *grandiflorum*, but is more robust and has larger fls. of richer color. Var. *nanum*, Pfitz. Dorsal sepal small, only about 1 in. long; petals somewhat falcate, about $1\frac{1}{4}$ in. long, with 2-4 warts. Var. *nigrum*, Pfitz. (*Cypripedium nigrum*, Reichb. f.). Dorsal sepal oblong, acute; petals narrower. Perhaps

a natural hybrid. Borneo. Var. *nigrum*, Pfitz. Dorsal sepal very large, oval, strongly lined with deep crimson and shaded violet-purple, the center greenish white, the border broad white; petals bronzy black above; lip blackish brown. A. F. 36:1184. Gng. 20:34. Var. *O'Brienii*, Pfitz. Dorsal sepal small, less than 1 in. long; petals falcate, with 6-8 warts. Var. *orbum*, Pfitz. (*Cypripedium orbum*, Reichb. f.). Fls. paler than in the type. Var. *porphyreum*, Pfitz. Dorsal sepal very broad, round, reticulated, reddish violet on a white ground, the border pure white; petals olive-green above, rose-violet below; lip very large, blackish brown. Var. *pulcherrimum*, Pfitz. Perhaps a natural hybrid between *P. Hooker* and *P. hirsutissimum*. Var. *superbum*, Pfitz. Dorsal sepal orbicular, very flat, striped with very deep crimson and black-veined; petals reddish wine-color above, and olive-brown below with a central black band. Var. *Warneri*, Pfitz. Dorsal sepal very broad, nearly orbicular, white, strongly lined with dark green, stained with red-magenta, with a broad white border; petals shining dark green above; lip deep maroon. Other varieties known are: *giganteum*, *gracile*, *mosaicum*, *nobile*, *pictum*, *plumdosum*, *purpureum*.

41. *callodum*, Pfitz. (*Cypripedium callodum*, Reichb. f.). Lvs. acute, up to 10 in. long; tessellated: scape longer than lvs., brownish purple, 1-, or sometimes 2-fl.; fls. 4 in. greatest diam.; dorsal sepal broadly ovate, cordate, white, veins green at base, deep purple above, alternately longer and shorter; petals spreading, ligulate, pale green, tinted pale rose at apex, with 4 or 5 blackish warts on upper margin; lip helmet-shaped, brownish purple, the infolded lobes purple-spotted. Feb., March. Siam. R. H. 1888:252. L. 2:73. C. O. *Cypripedium* 7. Var. *giganteum*, Pfitz. Dorsal sepal broad, white, shaded with emerald-green lined with deep green. Var. *Rossianum*, Pfitz. Petals longer, narrower, and strongly falcate. Var. *Sänderæ*, Pfitz. Fls. white, the dorsal sepal green-veined. C. O. *Cypripedium* 15a. Var. *Schmidtianum*, Pfitz. (*Cypripedium Schmidtianum*, Kranzl.). Petals at base deflexed; lobes of the lip inflexed, thickened, subacute at apex; stam-inodium less angled, nearly orbicular. Var. *sublæve*, Pfitz. Petals without warts or hairs on the surface. Var. *viridiflorum*, Pfitz. Dorsal sepal and petals greenish white, veined with deep gray.

42. *Lawrenceanum*, Pfitz. (*Cypripedium Lawrenceanum*, Reichb. f.). Lvs. up to 10 in. long, $2\frac{1}{2}$ in. broad, tessellated: scape longer than lvs., brownish purple, pubescent, 1-, or rarely 2-fl.; fls. 4-5 in. greatest diam.; dorsal sepal nearly orbicular, white, the veins alternately longer and shorter, deep purple, the central ones usually green at base; petals spreading, ciliate, ligulate, green, the tips purple, each margin with 5-10 blackish warts; lip dull purple, brown-tinged above, green beneath. April-July. B. M. 6432. I. H. 30:478. F. S. 23:2372. G. C. III. 21:291. G. Z. 24. p. 1. J. H. III. 51:51; 63:545. Var. *Abbottianum*, Pfitz. Fls. large, the dorsal sepal with veins deep crimson. Var. *atropurpureum*, Hort. Same as following. Var. *atrorubrum*, Pfitz. Fls. richly colored, especially the dorsal sepal. Var. *biflorum*, Pfitz. Scape 2-fl., the lower fl. is normal, while the dorsal sepal of the upper fl. is reflexed. Var. *coloratum*, Pfitz. Dorsal sepal subacute, internerves pale violet, warts of the petals numerous. Var. *expansum*, Pfitz. Dorsal sepal much larger than in the type; petals larger. Var. *Grenièri*, Pfitz. Dorsal sepal very broad, round, emerald-green at base, with numerous deep blackish purple veins above, the ground-color white, shaded rosy magenta, the border white; petals emerald-green above, greenish white beneath, lined with rose; lip well developed, reddish maroon above, greenish yellow below. Var. *Hyeianum*, Pfitz. Dorsal sepal white, green-veined; petals horizontal, very long, white, green-dotted; lip olive. G. C. III. 21:37. Var. *magnificum*, Pfitz. Dorsal sepal deep

green at base, with a broad white border, lined with blackish purple at center. Var. *Moënsii*, Pfitz. Dorsal sepal broad, strongly lined with blackish purple and carmine, the border pure white; petals sea-green; lip brownish maroon with a white terminal spot. Var. *pleioleucum*, Pfitz. Dorsal sepal white above, the

2760. *Paphiopedalum* *Leeanum*. Hybrid. (See supplementary list.) (×½)

green veins short. Var. *stenósemum*, Pfitz. Dorsal sepal much narrower than in type, elliptic. Other varieties known are: *auriculum*, *gigantem*, *grande*, *Länderii*, *marmoratum*, *nigrum*, *pictum*, *Pitcherianum*, *purpurascens*, *roseum*, *superbum*, *virescens*.

The following list contains some of the hybrids. Many others are grown by fanciers but cannot be mentioned here. For catalogues of hybrids, see G.C. III. 17:199, A.G. 16:118, and the "Orchid Stud-book," by Rolfe & Hurst. *P. Acis*=*P. Lawrenceanum* × *P. insigne* Maulei.—*P. Acme*=*P. nitens* × *P. Bessie K. Pitcher*.—*P. GEORGE V. NASH.

PAPYRUS (an ancient name, coming through the Greek, and from which comes indirectly the word *paper*). *Cyperaceæ*. A group of aquatic or subaquatic very ornamental plants, now considered to represent one polymorphous species; by modern authors they are placed in the genus *Cyperus* (which see, page 941, Volume II).

The paper-reed, *Cyperus Papyrus*, Linn. (*Papyrus antiquorum*, Link. *P. sicula*, Parl. *Cyperus syriacus*, Parl.),

2762. *Papyrus antiquorum*.

Fig. 2762, is of the Nile region and widespread in Trop. Afr., also of Sicily. It is a glabrous perennial with a woody rhizome, reaching 10-15 ft. in height in favorable regions, the tall sts. solitary or very few from each root and varying from nearly terete to acutely 3-angled; lvs. all radical (only sheaths produced on the flowering culm), long and sedge-like; umbel compound on the top of the high culm, the primary rays many and 6-20 in. long, drooping; spikelets $1 \times 1\frac{1}{2}$ in., with

many spreading spikelets; wings of rachilla lanceolate, yellow, falling early with the glumes; stamens 3, the anthers joined by a crested connective: nut or fr. ellipsoidal, 3-cornered, gray. Var. *antiquorum*, Clarke (*P. antiquorum*, Willd. *P. mossambicensis*, Parl. *Cyperus Papyrus*, Linn., in part), has spikelets more or less deciduous above the 2 lowest or empty glumes, the wings of the rachilla obtuse and tardily falling, the connective not crested. This variety occurs in Trop. and N. Afr. and in Palestine.

The papyrus is popular about large tanks or aquaria in greenhouses, and is often bedded out about ponds in summer. Far South it may stand in the open. It is much used in California for adornment of lawns, doing well even with a moderate supply of water. The fluffy heads make attractive house decoration. The papyri of the ancient Egyptians were made of strips taken from the culm or stem, from base to apex, between the cortex and the core, being laid side by side and beaten and pressed together to form a continuous surface.

The paper-reed is known best to horticulture as a tender decorative plant, almost solely as an aquatic. It stands by itself, unequaled and unrivaled as such. It has tall dark green stems 10 or more feet high, depending on mode of culture, surmounted with an umbel of threadlike leaves or filaments, subdivided, and forming a most graceful and ornamental object. It is at home on the margin of a natural pond, or it may be planted in a tub or box of rich soil and placed in the artificial pond, but should be only slightly submerged. The plant should not be subjected to a spray from a fountain jet, as the weight of water will bend and break the stems. They may also be planted in groups similar to cannas, but should receive copious supplies of water, otherwise they will be dwarf and stunted. Propagation is effected by seed. Sow and treat seedlings similar to *Cyperus alternifolius*, the common umbrella plant. Sow in early autumn or spring; seedlings will make good plants the same season. Winter the medium-sized plants in a cool greenhouse with all light and air possible, else the plants become drawn and weak and crippled with aphids. Large plants may be divided in spring. (William Tricker.)

L. H. B.

PARACHUTE FLOWER: *Ceropegia Sandersonii*.

PARADISEA (said to be from Paradise, of which this plant is supposed to be a fit inhabitant). Often written *Paradisia*. *Liliaceæ*. ST. BRUNO'S LILY. Hardy herbaceous perennial, a single species, with small white flowers, native in the Pyrenees, Apennines, Alps, and Juras.

St. Bruno's lily and St. Bernard's lily are advertised in catalogues of hardy herbaceous plants as *Anthericum Liliastrium* and *Anthericum Liliago*, but the former should be called *Paradisea Liliastrium*; the latter is St. Bernard's lily. Both have white fls., borne in early summer on scapes a foot or more high. The fls. of both are tipped green outside. The lvs. are linear, all radical, and a foot or so long. Both plants are natives of Cent. Eu., and by their popular names recall the life-saving monks of the Alps. It is no wonder, then, that they are often confused, although they belong to different subtribes. The *Paradisea* has larger fls., which are funnel-shaped rather than rotate, but the fundamental differences upon which *Paradisea* is made a separate genus lie in the stamens. In *Paradisea* (according to Bentham & Hooker) the anthers are attached at the middle of the back and are versatile; in *Anthericum* the anthers are attached at their base and are erect; moreover, the stamens of *Paradisea* are hypogynous; of *Anthericum*, perigynous. Following are some

of the other differences as given by Baker in Journ. Linn. Soc. 15:286, 287, 301 (1877):

Liliastrium, Bertol. (*Anthericum Liliastrium*, Linn. *Czackia Liliastrium*, Andr.), has 6-8 lvs.: scape 12-24 in. high; raceme 2-10-flid.; bracts lanceolate; perianth 18-21 lines long; style 15-18 lines long; ovary and caps.

2763. *Paramigyna monophylla*. ($\times \frac{1}{2}$)

oblong.—*Anthericum Liliago*, Linn., has 12-20 lvs.: scape 6-15 in. high; raceme (sometimes paniced) 10-20-flid.; bracts linear; perianth 6-9 lines long; style 5-6 lines long; ovary and caps. globose. Some of the above characters may not hold for cult. plants.

Var. *major*, Hort., is much larger and a better form than the type, growing 2-3 ft. high and bearing more and larger fls. Gn. 9:12 (as *Anthericum Liliastrium* var.) has fls. 2 in. long and $2\frac{1}{2}$ in. across. Var. *giganteum*, Hort., is probably the same. *P. Liliastrium* and its varieties are plants of secondary importance in the hardy border; they are of simple cult.; prop. by division, or by seeds sown as soon as ripe.

WILHELM MILLER.
L. H. B.†

PARADISE FLOWER: *Strelitzia Reginae*.

PARAMÍGYNA (from the Greek to mix with). *Rutææ*, tribe *Citræ*. Evergreen climbing shrubs native to India and distantly related to the orange, but having fruits filled with gum.

Leaves alternate, unifoliate, articulated with the long petiole; spines recurved: fls. solitary or in clusters in the axils of the lvs., large, white, 4-5-merous with 8-10 free stamens; ovary 3-5-celled with 1-2 ovules in each cell: fr. globose or elliptical, gummy, with a lemon-like peel.—Several species are known. The following is being tested as a stock by the U. S. Dept. of Agric.

monophylla, Wight. Fig. 2763. An evergreen climbing shrub related to *Citrus*: lvs. simple, alternate; spines recurved: fls. large, white, 4-5-merous, with free stamens: the young lvs. are pendent, the twigs, spines, petioles and leaves are all more or less hairy. Talbot, For. Fl. Bombay, p. 200, fig. 122. Wight, Ill. Ind. Bot., pl. 42.

Several other species occur in the Indo-Malayan region; two have recently been described from the Philippines: *P. longipedunculata*, Merrill, a scandent shrub, closely related to *P. monophylla*, from which it differs in its longer peduncles and several other characters; *P. mindanaensis*, Merrill, a nearly glabrous scandent shrub, with shining lvs. and glabrous fr., usually curved.

WALTER T. SWINGLE.

PARA-NUT: *Bertholletia*.

PARASITE. A parasitic plant or animal is one which fastens itself upon another living thing, penetrating the tissues of the host or organism attacked, thus usually deriving some or all of its nutriment therefrom. Parasitic plants are numerous, but the larger part of them are to be found among the fungi and the bacteria. These two classes of organisms are the chief causes of plant diseases,—such as rusts, smuts, mildews, and blights. It is with such parasites as these that plant pathology is primarily concerned, and path-

ologists estimate that in the United States alone the annual losses to crops from parasitic fungi and bacteria amount to not less than \$600,000,000. Parasitic fungi commonly grow within the tissues of the host plant, reaching the surface only when forming certain types of spores, or propagative bodies. Parasites invariably cause some disturbance of the normal development of the tissues. Notwithstanding this fact, it can be said that there are beneficial parasites, such as the bacteria producing the nodules, or tubercles, on the roots of legumes; and these nodules are important because of the fixation therein of atmospheric nitrogen, which ultimately becomes a source of nitrogen supply for the legume host.

There are also parasites among flowering plants. Of these, two principal classes may be noted: (1) those green in color, or chlorophyll-containing, such as the mistletoe and the bastard toad-flax; and (2) those practically devoid of chlorophyll, such as the dodder and the broom-rape. The members of the first class are commonly supposed to be active photosynthetically, that is, they are able to manufacture their own carbonaceous food-supply from carbon dioxide and water, while members of the second class must receive all or nearly all similar foods through the host plant. Plants living upon dead organic substance are termed saprophytes (which see). There are all gradations between parasites and saprophytes, especially among the fungi. Some are parasitic during their more active vegetative growth, and then continue their development saprophytically. Again, there are many fungi which, while generally parasitic, may be grown in the laboratory upon a variety of culture media, or cooked plant products. Finally, there are those which ordinarily live saprophytically in the soil, but under certain conditions are able to induce disease epidemics.

B. M. DUGGAR.

PARATRÔPIA (Greek, *turned away*, probably with reference to the twining habit). *Araliaceæ*. Twining trees or shrubs similar to *Aralia*, with compound lvs.: infl. paniculate or racemose. The genus is now included in *Scheffera* by most authorities. *P. Steltzneriana*, Barb.-Rodr. The plant intro. into Calif. under this name grows up to 24 ft. high, evergreen; lf. palmately 6-foliate; lflets. leathery, oblong, short deltoid acuminate, petioles articulate at the petiole.

PARDÁNTHUS: *Belamcanda*.

PARIETÀRIA (from *parietarius*, belonging to walls, referring to its habitat). *Urticaceæ*. Annual or perennial herbs widely scattered in the temperate zones, scarce in the tropics. Fls. polygamous, cymose or glomerate at the axils; perianth of the hermaphrodite and male fls. deeply 4-lobed, rarely 3-lobed; lobes valvate; of the female fl. distinctly tubulous at the base, lobes shorter; stamens 4, rarely 3; ovary free within the perianth; stigma penicillate, short or linear: achene included in the persistent perianth. Ten or more species. *P. arborea*, Ait., an erect shrub, with lvs. perfectly white underneath, has been offered in trade-lists. This belongs in the genus *Gesnouinia*, differing from *Parietaria* in being small trees with the involucre subtending 3-fl. glomerate-panicled branches: fls. monœcious, the central pistillate, with the achene included in the tube of the involucre. *Gesnouinia* contains 2 species belonging to the Canary Isls.

PÂRIS (the berry of the plant is compared to the apple of discord, while the four leaves surrounding it are likened to Paris and the three envious goddesses, Juno, Minerva, and Venus. Others think the name is derived from *par*, equal, referring to the agreement in number between leaves and floral parts, and this is probably the correct derivation). *Liliaceæ*. **HERB-PARIS**. **LOVE-APPLE**. Hardy small herbs.

Differs from *Trillium* in having its floral parts in 4's instead of 3's. There are about 6 species altogether, and in some of them the floral parts are in higher numbers than four. They resemble trilliums in being small hardy rhizomatous plants, found in mountainous countries of the North Temperate Zone, and even in the arctic regions; also they have a single whorl of lvs. at the top of the scape and a single fl., but in Paris the outer perianth-segms. are more herbaceous and calyx-like, while the inner ones are much narrower and less showy, being mere strips of petal, or even entirely absent.

quadrifolia, Linn. **HERB-PARIS**. **TRUE-LOVE**. **FOUR-LEAVED GRASS**. Height 9-12 in.: lvs. all cauline, netted-veined (exceptional among monocotyledons): peduncle rising 1-2 in. above lvs.: perianth-segms. yellowish green, the 4 inner ones rather more yellow: berry bluish black. The dominant European type, scattered over Eu. and Siberia from the Arctic Circle to the Medit., in woods and shady places, but usually local. Gn. 31, p. 165.—Fls. in spring or early summer. Rarely the lvs. and floral parts are in 5's.

WILHELM MILLER.

PARÍTIUM: *Hibiscus elatus* and *H. tiliaceus*.

PARK: *Landscape Gardening*, page 1801.

PÁRKIA (named after Mungo Park, born in 1771). *Leguminosæ*. Tall unarmed trees: lvs. evenly bipinnate; lflets. very numerous, small: fls. in dense, long-peduncled, obovoid heads; calyx tubular, shortly 5-cleft; corolla tubular, somewhat cleft; stamens 10; ovary stalked: pod large, flat, strap-shaped, coriaceous.—About 10 species, tropics of both hemispheres. *P. timoriána*, Merr. **CUPANG**. A very large tree, up to 115 ft. high, with vase-shaped, wide-spreading crown: lvs. fernlike, with very small lflets: fls. small, white and yellow, in dense pear-shaped panicles: pods pendulous, flattened, black, 18 in. long. Timor and Philippines. Intro. in U. S. by Dept. of Agric. and offered for distribution.

PARKINSÔNIA (John Parkinson, 1567-1629, London apothecary, author of the delightful "Paradisus Terrestris" and "Theatrum Botanicum"). *Leguminosæ*. Tropical trees or shrubs, with a thin smooth bark and armed with simple or three-forked spines.

Leaves alternate or fascicled, bipinnate, with 1-4 pairs of pinnæ; the common petiole short, often obsolete or spinescent; stipules minute or none: fls. yellow or whitish, on slender pedicels in short, loose axillary or terminal racemes; calyx 5-parted, produced at base and jointed upon the pedicel; petals 5, clawed, the upper one within and broader than the rest, somewhat cordate, the claw pubescent and nectariferous on the inner side; stamens 10, free, the upper one gibbous outside; ovary several-ovuled, shortly stipitate: pod compressed, leathery, 2-valved, linear to linear-oblong, more or less twisted, tapering at both ends; seeds compressed, albuminous, with a crusty brown testa.—Five species. The dominant type, both in the wild and in cult., is *P. aculeata*, the Jerusalem thorn, which is probably a native of Amer., but is naturalized or cult. in all tropical countries. One species is S. African, one is S. American, and the remainder belong to the region between Texas and S. Calif. *P. aculeata* is a thorny evergreen tree with feathery drooping branches and handsome yellow fls.; it is admirable for hedges, thrives in the driest places and can endure some cold. It has been cult. in European conservatories, being usually raised from imported seeds, but it is of difficult cult. *P. Torreyana*, though generally destitute of lvs., is known in N. Mex. as "palo verde," from the bright green color of the branches. It stands drought even better than *P. aculeata*. These plants belong to the same tribe with such fine northern trees as *Gleditsia*

and *Gymnocladus* and such southern kinds as *Cæsalpinia*, *Poinciana*, and *Colvillea*. They are little known horticulturally.

A. *Lfts. numerous; rachis flat, long.*

aculeata, Linn. JERUSALEM THORN. Small glabrous tree, up to 10 ft. tall, the slender zigzag branches often pendulous: lvs. 8–16 in. long, with spiny petioles $\frac{1}{2}$ –1 in. long; lfts. numerous, very small, distant, linear to linear-oblongate, $\frac{1}{2}$ –4 in. long, inequilateral, on slender petioles; rachis winged, $\frac{1}{2}$ –1½ ft. long: racemes slender, axillary, 3–6 in. long; fls. fragrant, pendulous; calyx glabrous, tube very short, lobes oblong, reflexed, exceeding the tube; petals yellow, $\frac{3}{8}$ – $\frac{5}{8}$ in. long, blades suborbicular or oval, longer than the claws; stamens and ovary pubescent: pods narrow, 2–4 in. long, constricted between the seeds; seeds oblong. Probably Trop. Amer. S.S. 3:131.

AA. *Lfts. few; rachis terete.*

Torreyana, Wats. Small tree, 18–25 ft. tall, with light green, smooth bark: young branches and lvs. sparingly pubescent: lfts. 2 or 3 pairs, oblong, obtuse, narrowed toward the scarcely oblique base, glaucous, about $\frac{1}{4}$ in. long: racemes terminal with rather long pedicels, jointed near the middle, but joint not evident until in fr.; petals bright yellow, a prominent gland on the upper one: pod acute, more or less constricted between the very thick ventral suture. Valley of the Colo. and eastward through W. Texas.—Usually naked in the S.W. as the lvs. are early deciduous.

P. L. RICKER.

PARMENTIÈRA (named after Ant. Aug. Parmentier, who intro. potato-cult. into France). *Bignoniaceæ*. Shrubs or small trees with spirally placed fls. in 3's: fls. from the old wood on rather long peduncles, almost regular; calyx spathe-like, splitting up one side; corolla campanulate-funnelform, little crooked, limb sub-2-labiate, posterior 2-parted, anterior 3-parted, lobes all broadly spreading; stamens 4, scarcely exserted; ovary sessile, 2-loculate, many-seeded: fr. elongate-cylindrical or oblong: lvs. alternate or subopposite, 3-foliolate or some simple, common petiole often broad. Species 2, from Mex. and Panama. **P. cerifera**, Seem., from Panama, called "palo de vela," or candle-tree, from its long cylindrical frs. which are smooth and white like candles, has been offered in the trade.

PARNÁSSIA (after Mt. Parnassus). *Saxifragaceæ*. GRASS OF PARNASSUS. Low-growing moisture-loving hardy perennial herbs of tufted habit, sometimes transferred to gardens.

Glabrous, from short rootstocks, mostly with scape-like sts.: lvs. simple and entire, mostly radical (or basal) and petiolate, 1 on the st. sessile and mostly small: fls. usually 1, white or yellow; calyx 5-parted; petals 5, withering, but deciduous; fertile stamens 5, alternating with the petals; staminodia present or represented by glands; ovary 1-celled; style very short or none; stigmas usually 4; ovules many: caps. 1-celled, with 4 placentæ projecting within, 4-valved (sometimes 3-valved).—In wet or moist places in temperate and subarctic regions in the northern hemisphere, about 25 species. They are suitable for shady positions along the water's edge, and are prop. by seeds or division. They commonly grow about 6 in. high, but attain 2 ft. They bloom from June to Sept.; the petals are conspicuously veined with green lines. The plant which Dioscorides called "grass of Parnassus" is *P. palustris*, the only species common in Eu. This is perhaps the best one for cult., but they are all much alike in horticultural value. Parnassias prefer a peaty soil, but such is not necessary. The species are usually tenacious of life and are good perennials. The N. Carolinian species are hardy N.

A. *Petals not clawed.*

B. *Rudimentary stamens 9–20 at the base of each petal.*

C. *Scape-lf. more or less clasping.*

palustris, Linn. GRASS OF PARNASSUS. Rootstock short and erect: lvs. ovate, usually cordate at the base; scape-lf. ovate or cordate, at or below the middle of st.: fls. $\frac{1}{2}$ –1 in. across; rudimentary stamens 9–15 scales at the base of each petal. Eu., Asia., N. Amer., south to Mich. and Wyo. Gn. 41, p. 500; 78, p. 450. G.L. 26:365. A.G. 13:696.

cc. *Scape-lf. not clasping.*

californica, Greene (*P. palustris* var. *californica*, Gray). Height 1–2 ft.: lvs. ovate or ovate-oblong, cuneate at base, 1–2 in. long; scape-lf. very small, and borne above the middle: fls. 1½ in. across; rudimentary stamens about 20 at the base of each petal. Calif.

BB. *Rudimentary stamens 3–5 at the base of each petal.*

caroliniæna, Michx. Rootstock erect, very short: height 8–16 in.: lvs. ovate, broadly oval or orbicular, more or less cordate at the base; scape-lf. borne below the middle: fls. $\frac{3}{4}$ –1½ in. across; rudimentary stamens usually 3 in each set. Swamps and low meadows, New Bruns. to Man., south to Va. B.M. 1459.

AA. *Petals clawed.*

B. *Rudimentary stamens usually 3 at the base of each petal.*

asarifolia, Vent. Rootstock erect, short and thick: height 10–16 in.: lvs. orbicular, kidney-shaped at the base, often 2–3 in. wide; scape-lf. clasping, borne at about the middle: petals entire. Wet places in high mountains of Va. and N. C. B.B. 2:184.

BB. *Rudimentary stamens 5–9 at the base of each petal.*

fimbriata, König. Rootstock ascending, short: height 1 ft. or less: lvs. kidney-shaped to cordate-ovate; scape-lf. cordate, more or less clasping, at or above the middle: petals fringed below the middle. Colo. to Calif. and north in Alberta and to Alaska.

P. rubicula, Wall. The largest and coarsest of all the species, and lacks the delicate beauty and white petals of *P. palustris*: lvs. elliptic-ovate; scape-lf. borne below the middle: petals shorter than in the other kinds as compared with calyx-lobes; rudimentary filaments 3, not topped by anthers. Himalayas. B.M. 6609.

WILHELM MILLER.

L. H. B.†

PAROCHËTUS (Greek, *beside*, and *ditch* or *canal*). *Leguminosæ*. A half-hardy perennial trailer, with foliage like the shamrock, but with each of the 3 lfts. marked at the base with a handsome brown crescent; the pea-shaped fls. have a cobalt-blue standard and pink wings. It is desirable for hanging-baskets, pots and rockeries, and is said to bloom the year round. *Parochetus* is a genus of one species. It is allied to the clovers, sweet clover, medick, and rest-harrow, and differs from them in having a more acute keel, a 2-valved pod, and the lfts. not stalked. It is a native of Trop. Asia and E. Afr., ascending the Himalayas from 4,000–13,000 ft. If seeds could be secured from the greatest altitude the plants might be hardy in the N. This plant was formerly offered by A. Blanc, of Philadelphia, under the name of shamrock-pea, or blue oxalis. It has recently been distributed by the U. S. Dept. of Agric. in an effort to give this attractive plant a place in American horticulture.

communis, Hamilt. SHAMROCK-PEA. BLUE OXALIS. Height 2–3 in.: rhizome thread-like, wide-creeping; petiole 2 in. long; lfts. obovate, emarginate, glabrous or slightly pubescent: peduncles 1–2-fld.; fls. $\frac{1}{2}$ – $\frac{3}{4}$ in. across, axillary: pod straight, glabrous, linear, $\frac{3}{4}$ –1 in. long. F.S. 15:1575.

P. L. RICKER.†

PARONYCHIA (old Greek name used by Dioscorides, meaning whitlow-wort, or a cure for whitlow, a disease of the fingers or toes). *Caryophyllaceæ*; by some sep-

arated in *Illecebrææ*. **WHITLOW-WORT.** Annual and perennial little herbs, without showy flowers, adaptable to rock-gardens and borders.

Plant tufted, low, with minute clustered fls. and silvery stipules; erect or diffuse, often dichotomously branching; lvs. opposite, broad or narrow, entire, the margins flat or very rarely recurved; stipules prominent, scarious, shining; fls. minute, without petals, axillary or rarely in terminal cymes, usually hidden among the stipules; sepals 5, awned; stamens 5; staminodia 5 (sometimes wanting), bristle-like or reduced to teeth; style 2-cleft; fr. an article inclosed in the calyx.—Species about 50, largely in the Medit. region, but widely distributed; several are native in the U. S. A very few are cult. in the hardy border. The two European species here given do not appear in the leading catalogues, domestic or foreign, but *P. serpyllifolia* is said to be much used for carpet-bedding abroad. *P. argentea* furnishes the Algerian tea. Allied to *Herniaria*, which see for generic differences. The species described below are perennials. They are of simple cult.; prop. by seed and division.

A. lvs. narrow, linear or awl-shaped.

argyrócoma, Nutt. (*Anýchia argyrócoma*, Michx.). Erect or ascending perennial, 3–8 in. high, making broad tufts or mats, clothed with silvery appressed scale-like hairs: lvs. linear; stipules silvery white, scarious, entire, usually shorter than the lvs.; fls. in forking cymes; bracts large, silvery, membranous; staminodia minute. Rocky places. Maine and N. H. to Ga. and Tenn.—Also called silver chickweed, silverhead, and silver whitlow-wort. The northern form is sometimes separated as var. *albimontana*, Fern., differing from the type (which occurs from Va. south) in having branches mostly floriferous rather than most of them sterile, lvs. glabrate and with involute margins, and calyx-awns subulate and glabrescent.—*P. argyrocoma* is not difficult of cult. and is prized for rockeries, its silvery tufted appearance lending a distinct charm to the collection for this purpose. Prop. by seeds and division.

dichótoma, Nutt. Woody at the base, glabrous or nearly so, tufted, 4–14 in. tall; stipules entire, often 5–6 lines long, tapering into a slender awn; fls. in forking cymes; awns of the calyx-segms. divergent; staminodia of minute bristles. Dry soil, Md. and N. C. to Ark. and Texas.

AA. lvs. rather broad, obovate or nearly so.

argétea, Lam. Prostrate diffuse perennial, with long branches: lvs. ovate to oblong or lanceolate, acute: fls. lateral and terminal, dense, intermixed with lvs.; bracts ovate, acute, much longer than the fl.; calyx-lobes semi-scarious, hooded, mucronate on the back near the apex. Common in dry places, Medit. region.—Foliage nearly glabrous.

serpyllifolia, DC. Prostrate creeping perennial: lvs. obovate, flat, rather fleshy; fls. terminal; calyx-lobes blunt. Arid parts of S. and E. Eu.—Foliage ciliate at the margin. A disputed plant. Probably a form of *P. capitata*, Lam.

WILHELM MILLER.
L. H. B.†

PAROSËLA. By some used instead of *Dalea*, p. 960.

PARRÔTIA (after F. W. Parrot, a German naturalist and traveler, afterward professor of medicine at Dorpat; 1792–1841). *Hamamelidææ*. Ornamental woody plants grown chiefly for their handsome foliage and also for their early appearing flowers.

Deciduous shrubs or small trees: lvs. alternate, short-petioled, crenate, with large caducous stipules: fls. small, in dense heads surrounded by an involucre of several bracts; petals wanting; calyx 5–7-lobed, embracing the pubescent ovary about half; stamens 5–15; styles 2: caps. 2-celled, with 2 beaks, dehiscent between

the beaks, with 1 oblong shining seed in each cell.—Two species in Persia and the Himalayas.

The parrotias are spreading shrubs or small trees with medium-sized orbicular to obovate-oblong leaves, small flowers in dense heads appearing before the leaves, and with fruit similar to those of the witch-hazel. The Persian species is hardy as far north as Massachusetts. Its chief beauty consists in the brilliant autumnal tints of the foliage, which changes to golden yellow, orange, and scarlet and remains a long time on the branches. The early appearing flowers with the purple pendulous stamens, are also attractive. The Himalayan species is more tender and its foliage turns only to pale yellow, but the flowers are somewhat more showy from their rather large white bracts. The parrotias grow in any well-drained soil and like a sheltered position. The wood is very close-grained, hard and strong, and therefore *P. persica* bears the name, "ironwood." The tough pliable branches of the Himalayan species are extensively used for basket-work and are also twisted into thick ropes used for the construction of twig-bridges over the great rivers of its native country. Propagation is by seeds and layers and also by greenwood cuttings under glass.

pérsica, C. A. Mey. Shrub or small tree, to 15 ft., with spreading branches: lvs. oval to obovate-oblong, obtuse, coarsely and crenately dentate above the middle, dark green above, pubescent beneath when young, 3–4 in. long; bracts of fl.-heads covered with dark brown tomentum; stamens 5–7, pendulous, with linear-oblong, purple anthers: fr. with recurved beaks. N. Persia. B.M. 5744.

Jacquemontiana, Deene (*Fothergilla involucrâta*, Falc. *Parrotiopsis involucrâta*, Schneid.). Spreading shrub or small tree, to 20 ft.: lvs. orbicular, crenately toothed, stellate-pubescent on both sides, 2–4 in. long; heads many-fl., with spreading white bracts sprinkled with a purplish scurf on the back; stamens about 15, erect, with yellow, oval-oblong anthers. Himalayas. B.M. 7501.

ALFRED REHDER.

PARROT'S BILL: *Clinanthus*.

PARROT'S FEATHER: *Myriophyllum*.

PÁRRYA (Capt. W. E. Parry, Arctic explorer). *Cruciferae*. Four or 5 N. American and a few Asiatic low perennial herbs, with thick caudices, scape-like peduncles, narrow lvs. and mostly racemose rose-colored or purplish showy fls.; sepals oblong and erect, the lateral ones gibbous at base; petals broad, clawed: pod broad and flat, mostly elliptic, with orbicular seeds. The parryas are alpine or boreal often arctic plants, and some of them will no doubt prove useful for the alpine garden. So far they are practically unknown in

American gardens. The most likely species to be used in rock-gardening is *P. Ménziesii*, Greene (*Cheiranthus Ménziesii*, Benth. & Hook.). It has a leafy scape 3–8 in. high, with a raceme of many fls., the petals nearly ½ in. long and bright purple: lvs. spatulate or oblanceolate, entire, densely tomentose. N. Calif., north to the Lower Columbia River. L. H. B.

2764. Curl-leaved parsley.

PARSLEY (*Petroselinum hortense*, which see). Fig. 2764. A leaf vegetable, used for garnishing and flavoring.

While indispensable in the market-garden, parsley is not usually found in the home-gardens in this country.

The addition of a bit of parsley foliage, finely chopped, heightens the flavor of soups, fish, and the like. The principal use of this vegetable, however, is for garnishing meats and fish and other dishes, and for this purpose it seems to be the vegetable *par excellence*, equally desirable in the home as on the hotel table.

A very few plants of parsley will suffice for the home-garden, and any spot of good soil will do for starting them from seed. Sow as early in spring as practicable, either in an early hotbed or coldframe, or in open ground. Parsley seed germinates somewhat slowly, and the plants are feeble at first. In open ground, early sowing aids the plants to get ahead of the weeds. In larger patches the rows should be a foot apart, and seed sown rather thinly in shallow drills. Thin the plants to stand 4 to 8 inches apart, and cultivate same as carrots. Gather the leaves as needed. For use in winter and early spring, start plants in open ground in early fall, and on the approach of cold weather set them in a corner of the greenhouse bench, or in a box or keg filled with rich loam placed in a light kitchen or cellar window. Old roots, if still vigorous, may be lifted in autumn and treated the same as seedlings. Parsley will stand considerable frost. Although biennial or perennial, a new stock should be started every year. The plants usually bear better if the leaves are removed a few at a time rather than to have the entire crown cut at once.

When the plant is a year old (sooner or later), it throws up seed-stalks, and produces seed in abundance, even under glass protection. By keeping the seed-stalks closely cut out, the season of leaf-yield may be prolonged for a time. Seed is easily gathered and cleaned.

The varietal differences lie chiefly in the foliage, which in some sorts is rather coarse, as in the Plain or Common, or more finely divided, as in the Curled, Double Curled, Moss Curled, and Fern-leaved.

T. GREINER.
L. H. B.†

PARSNIP (*Pastinaca sativa*, which see). Fig. 2765. A favorite vegetable, cultivated for its edible root, which is used mostly in winter and spring.

The average home-gardener thinks much of quick results. The drawback to parsnip-growing, in his estimation, is the length of time the crop requires for its development. When seed is sown, in early spring, the harvest seems a long way off. To offset this disadvantage, however, parsnips become available as green material when other things fresh from the garden are very scarce or entirely absent, that is, in open spells in winter, and in the very early days of spring. A crop of good straight roots may not be so easily produced as a crop of smooth carrots, but when once grown it does not burden one with much responsibility in regard to storage or keeping, which is an important point in its favor. The roots may be left in the ground where they grew or stored in moss or sand in the cellar. The winter freezing in the ground does not injure them; in fact, some growers suppose that it improves the quality. This ability to withstand the winter makes them valuable also as food for cattle, sheep, hogs and poultry in the early spring, in case the table or market should not call for them at that time. If dug in autumn, they may be stored in a cool, moist cellar (or buried) as other roots are kept.

The best soil for parsnips is a clean rich loam, which offers no obstruction to the uniform expansion of the roots. Straight deep roots must have a deep soil. Prepare it the same as for beets or carrots, or for any other garden crop. The seed should be strictly fresh, as it soon loses its vitality. Seeds germinate rather slowly and therefore the ground should be clear of roots and seeds of weeds, otherwise the young plants may be smothered. Sow in early spring, preferably with a garden seed-drill, $\frac{1}{2}$ to 1 inch deep, in rows 15 to 20 inches apart in the garden, and somewhat farther in field culture, in the place where the plants are to stand.

Be prompt in thinning the young seedlings to 6 to 12 inches apart in the row; at the same time pull up or cut out all weeds. The free use of the hand wheel-hoe will keep the patch clean until the entire surface of the ground is covered with foliage, thus preventing further growth of weeds. Tillage may then cease.

Seed is easily grown. Plant the roots in spring in any good soil, and gather the seed-heads in summer when most of the seeds in them are mature. Dry them on sheets, and then thrash or strip.

The varieties of parsnip are few in number. For shallow, stony or otherwise unfavorable soils the best varieties are the Round or Early Short Round; for better soils the Half-Long, Student, or Hollow Crown; and for deep clean soils the Long Smooth. T. GREINER.

L. H. B.†

PARSÓNIA (after

John Parsons, a Scotch naturalist). *Apocynaceæ*. Twining shrubs with opposite lvs.: calyx 5-parted, glandular or naked, or with 5 scales; corolla salver-shaped, tube short; lobes overlapping to the right; stamens inserted in the

tube, filaments often twisted, anthers conniving over and adhering to the stigma, cells spurred and empty below; disk of 5 lobes or scales; ovary 2-celled, cells many-ovuled.—About 20 species in Trop. Asia, Austral., and New Zeal. The genus as here defined is that of Robert Brown; some recent authors have revived the older genus of the same name of Patrick Browne, making it supplant the usual species of *Cuphea* (p. 913). *P. Páddisonii*, R. T. Baker, is reported as under cult. It is a woody climber with glabrous sts., attaining a height of about 15 ft., and with stalked obovate-lanceolate lvs. This species produces tubers the size of beet-root, which are used as food by colonists as well as natives of New S. Wales. R.H. 1901:322 (note).

PARTHENIUM (ancient name transferred to this plant). *Compósitæ*. About a dozen perennial or annual, mostly canescent or pubescent, rather coarse herbs or shrubs of the western hemisphere, only rarely taken to gardens and apparently not domesticated. The heads are only inconspicuously rayed and not specially showy, the ray-florets about 5. *P. integrifolium*, Linn., the AMERICAN FEVERFEW, or PRAIRIE DOCK, has been offered as an ornamental hardy herbaceous perennial, but the plant is desirable only for foliage effects; and the fls. are not attractive. It is pictured in B.B. 3:411 and described in American manuals; it grows on dry soils from Minn. to Ga.: stout, to 4 ft., from a tuberous rootstock: lvs. ovate or ovate-oblong; heads many in a dense corymb, the rays whitish. The so-called "guayule rubber" of Mex., *P. argentatum*, Gray, the difficulty of growing which has caused much discussion, is reported as being under cult. in Mexico City by M. Calvino. It is unknown in horticulture.

PARTHENOCÍSSUS (Greek, *parthenos*, virgin, and *kissos*, ivy; translation of its French name). Syn. *Quinária*, *Psédera*. *Vitacæ*. Woody vines planted chiefly for their handsome foliage.

2765. Parsnip.

Deciduous or rarely evergreen shrubs climbing by means of tendrils with adhesive tips, rarely these tips not developed: bark with lenticels; pith white: lvs. alternate, digitate or 3-lobed, long-petioled: fls. in peduncled compound cymes opposite to the lvs., often crowded at the end of the branches and forming panicles, perfect, rarely polygamous; calyx minute, petals 5, rarely 4, spreading; stamens 5 or 4; style short and thick; a distinct disk wanting; ovary 2-celled, each cell with 2 ovules: fr. a 1-4-seeded berry.—About 10 species in N. Amer., Mex., E. Asia, and Himalayas. Formerly usually classed with *Ampelopsis*, which see for the differentiating characters between the allied genera.

These are high-climbing vines with handsome three- to seven-foliolate or three-lobed leaves assuming beautiful tints in autumn and with small greenish flowers in cymes or panicles followed by bluish black or black berries. They are particularly valuable as they cling firmly to walls and trees by means of adhesive tips of the tendrils without any other support. *P. quinquefolia*, *P. vitacea*, and *P. tricuspidata* are hardy North, while the other species are more or less tender; *P. Henryana* may be grown in the greenhouse for its beautiful foliage. In humid and good soil all species grow vigorously and soon cover large spaces. Propagation is by seeds or by hardwood cuttings or by layers, but *P. tricuspidata* and its varieties are usually grown from greenwood cuttings.

A. Lvs. 5-foliolate.

B. Young branchlets terete: lvs. green.

vitacea, Hitch. (*P. quinquefolia*, Graebn. *Ampelopsis quinquefolia* var. *vitacea*, Knerr. *A. dumetorum*, Hort. *P. dumetorum*, Rehd. *P. laciniata*, Small). Usually low and rambling over bushes, occasionally climbing high into trees, glabrous: tendrils with 3-5 twining branches only exceptionally ending in adhesive disks: the young growth green: lfts. oval or elliptic to oblong, acuminate, usually cuneate at the base, dark green and lustrous above, lighter green and usually lustrous below, coarsely serrate, glabrous, 2-5 in. long: cymes dichotomous on peduncles $1\frac{1}{2}$ -3 in. long, opposite the lvs.: fr. bluish black, about $\frac{1}{2}$ in. thick, usually slightly bloomy, with 3-4 seeds. June, July; fr. July, Aug. E. Canada and

2766. *Parthenocissus quinquefolia*.—Virginia creeper. ($\times \frac{1}{2}$)

New England to Assiniboia and from Mich. south to Texas and Colo. B.M. 2443. S.T.S. 1:89. Var. *laciniata*, Rehd. (*P. quinquefolia* var. *laciniata*, Planch.). Lfts. smaller, narrower, more deeply and incisely serrate, usually yellowish green. Wyo. to New Mex. Var. *macrophylla*, Rehd. (*Ampelopsis macrophylla*, Hort. *A. quinquefolia* var. *latifolia*, Dipp. *A. Røylei*, Hort.). Lfts. elliptic, large, dark green, sometimes 8 in. long and 5 in. broad. Garden form. Var. *dubia*, Rehd. (*P. hirsuta*, Graebn.). Young branchlets and lvs., at least on the veins beneath, more or less hairy.—This species is somewhat harder than the following, but does not cling to walls; it may be used for covering

trellis-work. The foliage is darker green and more lustrous.

quinquefolia, Planch. (*Vitis quinquefolia*, Lam. *Ampelopsis quinquefolia*, Michx. *A. hederacea*, DC. *A. virginiana*, Hort.). VIRGINIA CREEPER. Fig. 2766. High-climbing: tendrils with 5-8 branches ending in adhesive tips: the young growth purplish: lfts. elliptic to obovate-oblong, acuminate, usually cuneate at the base, coarsely and often crenately serrate, dull green above, glaucescent beneath: cymes crowded into terminal panicles: fr. bluish black, slightly bloomy, about $\frac{1}{2}$ in. thick, with usually 2 or 3 seeds. July, Aug.: fr. in Sept., Oct. New England south to Fla. and Mex., west to Ohio, Ill., and Mo. Em. 2:535. S.T.S. 1:88. Var. *murorum*, Rehd. (*P. quinquefolia* var. *latifolia*, Rehd. *P. radicansissima*, Graebn. *Ampelopsis muralis*, Hort. *A. radicansissima*, Schelle). Tendrils with shorter and more numerous, usually 8-12 branches: lfts. generally broader, the outer ones usually broadly ovate and rounded at the base. This is a more southern form and somewhat tenderer. Var. *minor*, Rehd., is similar to the preceding variety, but lfts. smaller and broader, oval to orbicular-ovate, rounded at the base, on slender stalks about $\frac{1}{2}$ in. long. Var. *hirsuta*, Planch. (*P. hirsuta*, Small. *Ampelopsis hirsuta*, Don. *A. Graebneri*, Bolle. *A. pubescens*, Schlecht. *A. quinquefolia* var. *radicansissima*, Rehd. *A. radicansissima*, Hort.). Young branchlets, infl. and the lvs. soft-pubescent, at least beneath, usually bright red while young, otherwise like the type. Gt. 48:1462. Var. *Saint-Paulii*, Rehd. (*P. Saint-Paulii*, Graebn. *Ampelopsis Saint-Paulii*, Hort.). Young branchlets and lvs. beneath pubescent: lfts. oblong-obovate, cuneate at the base, short-stalked or nearly sessile, sharply serrate with usually spreading teeth: panicles elongated: tendrils with 8-12 branches: aerial rootlets often present. Iowa and Ill. to Mo. and Texas. R.H. 1907, p. 567. Var. *Engelmannii*, Rehd. (*P. Engelmannii*, Graebn. *Ampelopsis Engelmannii*, Hort.), does not differ much from the typical form except in its generally smaller foliage.—The species is a very valuable climber of vigorous growth with the foliage changing to bright scarlet in fall; the varieties *hirsuta*, *Saint-Paulii*, and *murorum*, are particularly adapted for covering walls; they cling firmly and form a dense, close covering like *P. tricuspidata*, but grow more quickly and more straight upward than that species.

BB. Young branchlets quadrangular: lvs. usually with white markings above and purplish below.

Henryana, Diels & Gilg (*Vitis Henryana*, Hemsl. *Ampelopsis Henryana*, Hort.). Climbing to 20 ft. or more: tendrils with 5-7 slender branches with adhesive tips: lfts. 5, stalked, elliptic-ovate to cuneate-obovate, acuminate, toothed usually only above the middle, glabrous or hairy on the midrib beneath, $1\frac{1}{2}$ -2 $\frac{1}{2}$ in. long, bright scarlet when unfolding, changing finally to dull reddish green, with silvery markings along the veins above, purple or purplish beneath: fls. in narrow panicles, 3-6 in. long: fr. dark blue, usually 3-seeded. Cent. China. G.C. III. 37:309; 39:354. Gn. 69, p. 341. M.D.G. 1908:259. R.H. 1907, p. 211. R.H.B. 32:213.—This is a very handsome but tender species; the coloring of the lvs. is more beautiful when grown in the greenhouse or outdoors in a partly shaded place; in the full sun the lvs. lose finally the white markings and the purple color.

AA. Lvs. partly 3-lobed and partly 3-foliolate.

tricuspidata, Planch. (*Vitis incônstans*, Miq. *Ampelopsis tricuspidata*, Sieb. & Zucc. *A. Veitchii* var. *robusta*, Hort. *A. Hoggii*, Hort. *A. incônstans*, Hort. *A. japonica*, Hort.). JAPANESE IVY. BOSTON IVY. Fig. 2767. High-climbing: tendrils short, much-branched, with adhesive tips: lvs. slender-stalked, cordate, either simple and 3-lobed with acuminate serrate lobes, to 10 in. long, or 3-foliolate; lfts. ovate, sessile, serrate,

shining and glabrous on both sides or puberulous on the veins beneath: cymes mostly on short branchlets, axillary or terminal, narrow and somewhat elongated: fr. bluish black, bloomy. June, July; fr. in Sept., Oct. Japan, Cent. China. B.M. 8287. G.C. II. 14:664. A.G. 15:94. B.H. 27:244. R.H. 1877, p. 176. Gng. 1:373; 4:353. R.B. 1877:11. Var. *Veitchii*, Rehd. (*P. Veitchii*, Graebn. *Vitis Veitchii*, Hort. *Ampelopsis Veitchii*, Hort.). Lvs. smaller, crenately serrate, purple while young; lfts. with only 1-3 coarse teeth on each side, the lateral ones inside without teeth. Apparently only a juvenile form which may pass later into the type. Var. *purpurea*, Hort. (*Ampelopsis Veitchii* var. *purpurea* or *atropurpurea*, Hort.). Lvs. dark purple, not changing to green. Var. *Löwii*, Rehd. (*Ampelopsis Löwii*, Hort. *Vitis incansans* var. *Löwii*, Hort.). Lvs. small, $\frac{3}{4}$ -1 $\frac{1}{2}$ in. long, mostly entire or 3-foliolate, often broader than long, incisely dentate or almost palmately lobed with very unequal teeth, apple-green, purplish when young, changing to deep red in autumn. Gn. 71, p. 516. J.H. III. 56:335. R.H.B. 33:388. A.F. 30:1238. M.D.G. 1908:261. Var. *aurata*, Hort. Lvs. marbled with golden yellow and green.—This species is a hardy and very useful climber, clinging firmly and covering walls densely; the glossy foliage stands dust and smoke well, and turns to a brilliant orange and scarlet in fall. Probably the favorite of all hardy vines in cities. The varieties *Veitchii* and *Löwii* are much slenderer and smaller and are very effective as basket plants (M.D.G. 1892:8).

P. heptaphylla, Small (*P. texana*, Rehd. *A. quinquefolia* var. *heptaphylla*, Bailey. *A. heptaphylla*, Buckl.). High-climbing; tendrils with 2-4 branches without disks: lfts. usually 7, oblong-obovate, cuneate at the base, coarsely serrate, 1 $\frac{1}{2}$ -2 $\frac{1}{2}$ in. long; cymes dichotomous, opposite the lvs. Texas. S.T.S. 1:90.—*P. himalayana*, Planch. (*Ampelopsis himalayana*, Royle). Allied to *P. tricuspidata*; lfts. 3, ovate to oblong-ovate, the lateral ones rounded or subcordate at the base, coarsely serrate, 2-5 in. long; cymes about as long as the lvs. Himalayas. Var. *rubrifolia*, Gagnep. (*Vitis rubrifolia*, Léveillé & Vaniot). Lfts. smaller and broader, purplish while young; cymes smaller. W. China.—*P. latifolia*, Rehd. Allied to *P. quinquefolia*. Tendrils with 5-8 slender branches: lvs. obovate or elliptic, coarsely serrate, bright yellowish green on both sides, 2-4 in. long, glabrous or hairy on the veins below; fls. in large terminal panicles. Cent. China.—*P. Thomsonii*, Planch. (*Vitis rubrifolia*, Laws. *P. Henryana* var. *glaucescens*, Diels & Gilg. *Ampelopsis Thomsonii*, Hort.). Tendrils with 3-5 disk-bearing branches; lfts. 5, slender-stalked, elliptic-ovate to elliptic-oblong, cuneate, serrate, glabrous or slightly pubescent on the veins beneath, bluish green, 1 $\frac{1}{2}$ -3 in. long; fls. in dichotomous cymes 1 $\frac{1}{2}$ -3 in. broad, opposite the lvs.; fr. black. Himalayas, Cent. China. Gn. 63, p. 203. J.H.S. 28, p. 216, fig. 184.—A very handsome slender vine; foliage purplish while young, and purplish red in fall. Tender.

ALFRED REHDER.

PARTRIDGE-BERRY: *Mitchella repens*. Sometimes applied to *Gaultheria procumbens*.

PASANIA (the vernacular name of one of the species in Java). *Fagaceæ*. Ornamental trees grown for their handsome foliage.

Evergreen: winter-buds with few foliaceous scales: lvs. short-petioled, entire or dentate: staminate fls. in upright catkins, with a rudimentary ovary; stamens usually 12, much longer than the 4-6-lobed calyx; pistillate fls. solitary or 3-5, on separate catkins or at the base of the staminate catkins; ovary 3-celled, with 3 cylindric styles stigmatic only at the apex: fr. a 1-seeded nut, surrounded at the base or wholly inclosed by the cup, its scales distinct and imbricate or connate into concentric rings.—About 100 species in S. E. Asia, one in Calif. Closely related to *Quercus*, from which it is easily distinguished by the upright staminate catkins and the cylindric styles stigmatic only at the apex.—The *pasanias* can be grown in warmer temperate regions only and are little known in cult. Their treatment and propagation is the same as that of the evergreen species of oak.

densiflora, Oerst. (*Quercus densiflora*, Hook. & Arn.). **TANBARK OAK.** Evergreen tree, to 70, occasionally to 100 ft., with spreading branches forming a dense, broad, round-topped head: lvs. oblong-obovate or oblong, acute, remotely dentate, with short acute callous teeth,

fulvous-tomentose when young, at maturity glabrous and pale green above, rusty tomentose beneath and finally glabrous and bluish white: fr. peduncled; acorn ovoid or ovate, $\frac{3}{4}$ -1 $\frac{1}{2}$ in. long, embraced only at the base by the shallow cup coated with linear spreading scales. S. Ore. to Calif. S.S. 8:438. G.F. 5:523.—One of the most beautiful oaks of the Pacific states. The bark is exceedingly rich in tannin and is used for tanning leather. The only representative of the genus in Amer.

2767. *Parthenocissus tricuspidata*. ($\times \frac{1}{4}$)

P. cornea, Oerst. (*Quercus cornea*, Lour.). Evergreen tree: lvs. oblong, acuminate, glabrous and green beneath, 2-4 in. long; frs. in short spikes; cup broadly turbinate with small prominent scales embracing the hemispherical flat-topped nut. S. China. H.I. 27:2665. The nut is edible. Young plants have proved hardy at Washington, D. C.—*P. cuspidata*, Oerst. (*Quercus cuspidata*, Thunb. *Castanopsis cuspidata*, Schottky). Evergreen tree, to 40 ft., with slender branches: lvs. ovate to oblong, acuminate, crenately serrate toward the apex or entire, glabrous at length, 1 $\frac{1}{2}$ -3 $\frac{1}{2}$ in. long; fr. in short spikes; cup ovate, inclosing the acorn. S. Z. 1:2. G.C. III. 12:233. S.I.F. 1:34. Very desirable evergreen tree of vigorous growth. Var. *variegata*, Hort. Lvs. smaller, with a broad, irregular, creamy white margin. G.C. II. 12:233.—*P. glabra*, Oerst. (*Quercus glabra*, Thunb.). Evergreen tree: lvs. oblong, obtusely acuminate, entire, glabrous, light green beneath, 3-6 in. long; fr. in spikes, ripening the second year: the oblong nut embraced about one-third by the cup. Japan. G.C. II. 14:785; III. 16:377. R.H. 1858, p. 351. S.Z. 1:89. S.I.F. 1:32.—*P. thalassica*, Oerst. (*Quercus thalassica*, Hance). Evergreen tree: lvs. elliptic to obovate-oblong, acuminate, serrate toward the apex or entire, glaucous-tomentulose beneath, 3-5 in. long; fr. in short spikes; cup with appressed scales, embracing one-fourth to one-third of the nut. China. S.I.F. 1:33.

ALFRED REHDER.

PASCALIA: *Wedelia*.

PÁSPALUM (Greek, *paspalos*, an ancient name for millet). *Gramineæ*. Spikelets 1-flid., plano-convex, mostly rounded, subsessile and overlapping in 2 rows on one side of a narrow or winged axis forming slender racemes. About 150 species in the warmer parts of both hemispheres, but more abundant in Amer., forming an important part of the pampas and campos of S. Amer. *P. dilatatum*, Poir., of Argentina, a coarse species 3-5 ft. high, is sparingly cult. as a forage grass in the Gulf states and has become naturalized throughout the S. *P. compressum*, Nees, CARPET-GRASS, a native, 6 in. to 2 ft. high, with creeping sts. and rather broad lvs. makes a good lawn grass in the Gulf region; it is less difficult to eradicate than Bermuda-grass. *P. distichum*, Linn. Extensively creeping rather wiry perennial, the erect fl.-culms 6-12 in., bearing a pair of divergent spikes. Occasionally used for lawns in the South. S. U. S. to S. Amer. *P. membranaceum*, Lam. Slender perennial with few to several spikes, the silvery spikelets arranged on a broad ribbon-like axis, banded with drab and orange. S. Amer. Cult. in Eu. under the name *P. elegans*; worthy of intro. A. S. HITCHCOCK.

PASSERINA (Latin, *sparrow*, from the supposed resemblance of the seed to the head of a sparrow; or possibly after one of the Passerinis, two Italian botanists). *Thymelæaceæ*. Heath-like shrubs sparingly used in horticulture: lvs. small, decussately opposite: fls. hermaphrodite, in axillary, branched spikes; perianth-tube ovoid, with 4 spreading lobes often about as long as the tube; stamens 8; ovary subsessile, glabrous, 1-celled.—About 5 species from S. Afr. *P. filiformis*, Linn. Branches puberulent: lvs. acrose-linear, 3-cornered, rather acute: spikes terminal, many-fl.; fls. rose; calyx-lobes oval or oblong. S. Afr.

PASSIFLORA (i. e., *passion flower*). Including *Disémma* and *Tacsonia*. *Passiflorææ*. **PASSION-FLOWER**. Highly interesting herbs, shrubs, or trees, most of the cultivated kinds climbing by means of tendrils, with flowers of odd structure; some of them produce edible fruits.

Mostly vines, but some species erect: lvs. alternate, rarely opposite, the petiole usually gland-bearing, the blade entire, digitately lobed or parted, stipules sometimes present: tendrils (sometimes wanting) lateral, simple: fls. solitary or racemose, mostly axillary, on articulated and often 3-bracted peduncles, mostly hermaphrodite, with colors in yellow, green, blue and red, often large and showy; calyx with short tube (also with long tube when *Tacsonia* is included), the lobes or petals 4 or 5 and narrow, often colored inside, bearing on the throat a simple double or triple showy fringe or crown; petals 4 or 5 (sometimes wanting, or 3), attached on the calyx-throat; stamens 4 or 5, the filaments joined into a tube in which is the gynophore or stalk of the ovary, the anthers linear-oblong and versatile; ovary oblong or nearly globular, with 3 styles and 3 many-ovuled parietal placentæ: fr. large or small, berry-like, many-seeded, oblong or globular; seeds flat, mostly ovate, with a fleshy aril.—Species probably 250–300. By some, the genus *Tacsonia* is separated from *Passiflora*, but it is here combined; it differs in having an elongated rather than very short calyx-tube or hypanthium; Andean species. See *Tacsonia*.

With the exception of a few Malayan, Chinese and Australian species, the true *passifloras* are natives of tropical America, some of them in the sub-tropical and warm temperate parts. Many of them are cultivated as curiosities, and some of them for the beauty of their flowers and for their festooning foliage. The fruit is of many kinds, in most cases not edible. The ovary is supported on a long stalk, which is inclosed in or usually united with the tube formed by the union of the bases of the filaments. The structure of the fruit is well shown in Fig. 2768; the remains of the floral envelopes have broken from the attachment on the torus and rest on the fruit. A dozen *passifloras* occur in the United States, and one of them, *P. lutea*, grows naturally as far north as southern Pennsylvania and Illinois. From Virginia south, the Maypop, *P. incarnata*, is a very common plant in fields and waste places. Both these species are herbaceous perennials.

2768. Fruit of Maypop.—*Passiflora incarnata*. ($\times \frac{3}{4}$)

In cultivation, the *passifloras* have been considerably hybridized, and they are also confused with *Tacsonia*. In 1871 Masters enumerated 184 species (Trans. Linn. Soc. 27), but many species have been discovered since that time. Most of the *passion-flowers* are yellow or green in color of envelopes, but there are fine reds in *P. racemosa*, *P. Raddiana*, *P. coccinea*, *P. alata*, *P. vitifolia*, and others. The species known to gardeners are few, although many kinds are or have been in cultivation by fanciers and in collections. They usually require much rafter room in greenhouses. According to G. W. Oliver, *P. cærulea* and Constance Elliott are both hardy at Washington. Not many of the tender species and hybrids are grown to any great extent in this country. *P. alata* and *P. quadrangularis* are desirable climbers for a roomy warm greenhouse. *P. quadrangularis* var. *variegata* seems to flower quite as freely as the green-leaved one. *Passifloras* are propagated from cuttings of the half-ripened growth, with bottom heat. *P. racemosa* and *P. Loudonii* are a trifle difficult to root from cuttings; the growths should be as ripe as possible for this purpose. Keep the under surface of the leaves flat on the sand while rooting. The native *P. incarnata* grows very freely at Washington, becoming more or less of a weed and hard to eradicate.

The peculiar charm of these plants lies in the odd flowers, the parts of which were fancied by the early Spanish and Italian travelers to represent the implements of the crucifixion (whence both the technical and popular names). Legend and superstition have attached to these plants from the first. The ten colored parts of the floral envelope were thought to represent the ten apostles present at the crucifixion, Peter and Judas being absent. Inside the corolla is a showy crown or corona of colored filaments or fringes, taken to represent the crown of thorns, or by some thought to be emblematic of the halo. The stamens are five, to some suggestive of the five wounds, by others thought to be emblematic of the hammers which were used to drive the three nails, the latter being represented by the three styles with capitate stigmas. The long axillary coiling tendrils represent the cords or the scourges. The digitate leaves suggest the hands of the persecutors. The following sketch of the *passion-flower* legend is from Folkard's "Plant Lore, Legends and Lyrics," and the illustration (Fig. 2769) is also produced from that book: "The *passion-flower* (*Passiflora cærulea*) is a wild flower of the South American forests, and it is said that the Spaniards, when they first saw the lovely bloom of this plant, as it hung in rich festoons from the branches of the forest trees, regarded the magnificent blossom as a token that the Indians should be converted to Christianity, as they saw in its several parts the emblems of the passion of our Lord. In the year 1610, Jacomo Bosio, the author of an exhaustive treatise on the Cross of Calvary, was busily engaged on this work when there arrived in Rome an Augustinian friar, named Emmanuel de Villegas, a Mexican by birth. He brought with him, and showed to Bosio, the drawing of a flower so 'stupenduously marvellous,' that he hesitated making any mention of it in his book. However, some other drawings and descriptions were sent to him by inhabitants of New Spain, and certain Mexican Jesuits, sojourning at Rome, confirmed all the astonishing reports of this floral marvel; moreover, some Dominicans at Bologna engraved and published a drawing of it, accompanied by poems and descriptive essays. Bosio therefore conceived it to be his duty to present the *Flos Passionis* to the world as the most wondrous example of the *Croce trionfante* discovered in forest or field. The flower represents, he tells us, not so directly the Cross of our Lord, as the past mysteries of the Passion. It is a native of the Indies, of Peru, and of New Spain, where the Spaniards call it 'the Flower of the Five Wounds,' and it had clearly been designed by the great Creator that it might, in due time, assist in

the conversion of the heathen among whom it grows. Alluding to the bell-like shape assumed by the flower during the greater part of its existence (i.e., whilst it is expanding and fading), Bosio remarks: 'And it may well be that, in His infinite wisdom, it pleased Him to create it thus shut up and protected, as though to indicate that the wonderful mysteries of the Cross and of His Passion were to remain hidden from the heathen people of those countries until the time preordained by His Highest Majesty.' The figure given to the Passion-flower in Bosio's work shows the crown of thorns twisted and plaited, the three nails, and the column of the flagellation just as they appear on ecclesiastical banners, etc. 'The upper petals,' writes Bosio in his description, 'are tawny in Peru, but in New Spain they are white, tinged with rose. The filaments above resemble a blood-coloured fringe, as though suggesting the scourge with which our blessed Lord was tormented. The column rises in the middle. The nails are above it; the crown of thorns encircles the column; and close in the center of the flower from which the column rises is a portion of a yellow colour, about the size of a reale, in which are five spots or stains of the hue of blood, evidently setting forth the five wounds received by our Lord on the Cross. The colour of the column, the crown, and the nails is a clear green. The crown itself is surrounded by a kind of veil, or very fine hair, of a violet colour, the filaments of which number seventy-two, answering to the number of thorns with which, according to tradition, our Lord's crown was set; and the leaves of the plant, abundant and beautiful, are shaped like the head of a lance or pike, referring, no doubt, to that which pierced the side of our Savior, whilst they are marked beneath with round spots, signifying the thirty pieces of silver.' "

Passifloras as gardener's ornamental plants.

(J. J. M. Farrell.)

These plants constitute a large family or group of evergreen climbers. They will show to best advantage when they can be planted out permanently in a warm conservatory and where they can have comparatively large space to climb. They may also be grown in pots when the conditions do not permit other methods of handling.

Passifloras may be propagated either by cuttings or seeds. They may be rooted from young growth taken any time from the middle of January until April. These cuttings are placed in a warm propagating-bed, and kept shaded and moist, and in a short time they will root; they are also inserted in small pots in a mixture of loam, peat, and sand, in equal parts, and plunged in the propagating-bed. When rooted, the cuttings are potted off, using a compost of loam four parts, leaf-mold two parts, well-rotted cow-manure one part, and which should contain enough sand to keep it porous. Keep shaded until they become well established, when they may be given a place well up to the glass in full sun. The passifloras are also readily raised from seed sown in spring, and the plants potted off as soon as big enough.

The plants will stand a night temperature of 65° to 70°; this can be increased until it reaches 80° to 85° for a day temperature with sun. Give ventilation daily, taking into account the state of the weather; while they like plenty of heat, they will not do well in a stagnant atmosphere; therefore, give air on all favorable occasions. Every morning in bright weather, give them a good syringing, as this is a great aid in keeping them in vigor and supplying the desired atmospheric moisture, but this does not mean a very humid atmosphere. By pinching, the plants are made to produce several growths. These plants can be shifted until they are in 10- or 12-inch pots. The growth may be trained on pillars or along rafters of the conservatory.

When planted out in about 8 or 10 inches of soil, passifloras will cover a very large space, but sometimes to such an extent as to obscure the whole glass. The best place is on a back wall in some house where they may ramble at will. Keep well syringed until they show flower, when syringing should be discontinued until

2769. Old conception of the passion-flower.

From Folkard's "Plant Lore," and there taken from Zahn.

they are through blooming. After the plants have covered the position allotted to them, all that is required is the regulation of the young growth, so as to keep them from becoming entangled. In winter they may be cut back and the exhausted soil replaced by good rich compost. They will not need a high temperature, doing well in 55° to 60° at night. When they start off into growth again, keep raising the temperature until it has reached the figures already stated. They may now be given manure water regularly and throughout the growing season. Keep down thrip, red-spider, and mealy-bug by syringing and sponging.

The edible-fruited passifloras. (F. W. Popenoe.)

The principal species of Passiflora that are cultivated for their fruits in tropical and subtropical regions are *P. quadrangularis*, the granadilla, granadilla real of Costa Rica, barbadine of the French colonies, pasionaria of Cuba, maracujá melão of Brazil; *P. edulis*, also called granadilla, as well as passion-fruit; and *P. laurifolia*, the water-lemon of the British West Indies, pomme-liane of the French colonies. While *P. quadrangularis* is a common garden plant in tropical America, it is not so extensively grown in any region as is *P. edulis* in Australia. In the United States these species can be grown only in the warmest regions; in California *P. edulis* is the only one that is successfully cultivated in the open, the other two species being much more susceptible to frost; in south Florida all three can be grown, although the tropical species are sometimes injured by frost.

The true granadilla (*P. quadrangularis*) is a strong rapid-growing climber, frequently planted for ornament in tropical regions and allowed to cover arbors and pergolas. Its brownish yellow ovoid fruits are sometimes 8 inches in length, and within the thin brittle pericarp is a large number of small flattened seeds surrounded by gelatinous pulp and subacid juice. When green, they are sometimes boiled and used as a vegetable; when ripe, the acidulous pulp is refreshing, and is used to prepare cooling drinks, or is eaten with a spoon directly from the fruit.

The passion-fruit (*P. edulis*) is considerably smaller than the granadilla, rarely larger than a hen's egg, and dull purple when ripe. Its pulp is slightly more acid than that of the granadilla, but of very pleasant flavor, and highly esteemed in Queensland and New South Wales, where the plant is cultivated commercially. It is used for flavoring sherbets, for confectionery, for icing cakes, for "trifles,"—a dish composed of sponge cake, fruits, cream, and white of egg,—for jams, and for other table purposes. The pulp is also eaten directly from the fruit, after adding a little sugar, or is used to prepare a refreshing drink, by beating it up in a glass of ice-water and adding a pinch of bicarbonate of soda. The plants are grown on trellises about 6 feet high; at the top of the trellis is nailed a crosspiece 18 inches long, from the ends of which are run two wires, the long branches being allowed to hang down over these to the ground. The rows are placed 15 feet apart, with the vines 15 feet apart in the row. The young plants must be protected in regions subject to frost; they begin bearing the second year, sometimes producing a few

which have not yet come into bearing. Like *P. quadrangularis*, this species is often grown as an ornamental plant, and makes an excellent and rapid-growing cover for fences and trellises.

The passifloras are easily propagated by seeds or cuttings, the latter method being preferable in most cases. Seeds should be removed from the fruit, dried in a shady place, and planted in flats of light soil. They do not germinate very quickly, but the young plants are easily raised, and may be set out in the open ground when six months to a year old. Cuttings should be taken from fairly well-matured shoots, and should be about 6 inches in length. They are easily rooted in sand, no bottom heat being required. Cuttings of *P. edulis* will often fruit in pots at the age of one to two years, and form very interesting greenhouse plants. While this species usually fruits prolifically, *P. quadrangularis* sometimes requires hand-pollination when grown outside its native habitat.

I. PASSIFLORA proper, with short hypanthium or calyx-tube (species 1-24).

A. Corona with sharp folds, and crinkled at the edge.

B. Fls. apetalous, usually with no bracts.

1. *gracilis*, Jacq. Slender annual: st. terete, glabrous; lvs. rather small, broadly deltoid-ovate, very shallowly and bluntly 3-lobed: fls. solitary, pale green or whitish, considerably surpassed by the lvs., the calyx-lobes oblong or lanceolate, the filiform rays of the corona in a single row and equal, the inner corona a lacerated membrane: seeds with 6 elevated ridges. Brazil. B.R. 870.—Fl. about 1 in. across. Easily grown either indoors or in the open, as a garden annual.

BB. Fls. petaliferous, with large bracts.

2. *adenopoda*, Moc. & Sessé. Lvs. glabrous, cordate, 3-nerved and 5-lobed, the lobes ovate-acuminate and somewhat serrate: bracts cut-serrate. Mex. to S. Amer.—Once advertised in the U. S.

3. *Hahnii*, Mast. Tall, glabrous climber, with very slender terete pendulous branches: lvs. ovate, peltate at base, strongly 3-nerved and each of the side nerves ending in a tooth, but the lf.-margin otherwise entire but bearing minute red glands: stipules kidney-shaped, dentate, purplish, nearly or quite 1 in. across: fl.-bracts 2, entire: fl. about 3 in. across, solitary, whitish and pale green, the corona shorter than the envelopes, the outer filaments being orange-yellow, about $\frac{3}{4}$ in. long. Mex. B.M. 7052. R.H. 1869:430 (as *Disemma Hahnii*). G.C. II. 12:504.

BBB. Fls. with small or minute petals and also small or minute bracts.

C. Lvs. oblong-ovate.

4. *trifasciata*, Lem. Lvs. 3-lobed to one-third or one-half their depth, the margins entire, with an irregular

2770. Granadilla—*Passiflora quadrangularis*. ($\times \frac{1}{2}$ — $\frac{1}{4}$)

fruits the first season, and continue in profitable production four to six years, when they must be renewed. By proper pruning, two crops a year can be secured, in regions not subject to frost. The most suitable soil seems to be sandy loam, although other soils will grow the plant successfully. Manure should be supplied liberally. In Australia, the profits of passion-fruit culture are reported to run from \$100 to \$300 an acre annually. Because of the short life of the vines, they are often planted as a catch-crop in young orchards

reddish purple band along each of the 3 midribs: fls. yellowish, fragrant, small. Brazil. I.H. 15:544. G.Z. 12:96.—Interesting for its ornamental foliage.

cc. Lvs. broader than long.

5. *lutea*, Linn. WILD YELLOW PASSION-FLOWER. Perennial herb, 5–10 ft. tall or long, glabrous or very nearly so: lvs. broader than long, shallowly and bluntly 3-lobed, cordate at base, the petiole glandless: fls. solitary or in pairs, about $\frac{3}{4}$ in. across, greenish yellow: fr. a globular berry about $\frac{1}{2}$ in. diam., smooth, purple at maturity. Pa. south and west, in thickets and more or less damp places. B.R. 79.—It has been offered by dealers in native plants.

6. *maculifolia*, Mast. Notable for its spotted or variegated foliage: branches slender and wiry, puberulous: lvs. short-stalked, roundish cordate, 3-nerved, with 3 shallow lobes at the truncate apex, green and yellow-blotched above, purplish and glandular beneath: fls. in pairs, cream-colored, nearly 1 in. across, the peduncles with 3 remote minute bracts; calyx cup-shaped, with acuminate recurved lobes; petals shorter than calyx-lobes or sepals; crown plicated and with hatchet-shaped processes. Venezuela. G.C. III. 32:suppl. Nov. 8.

AA. Corona not crinkled or folded on the edge, plain or nearly so.

B. Bracts grown together.

7. *ligularis*, Juss. (*P. Löwei*, Heer). Woody below, tall, branchy: lvs. large, cordate, ovate-acuminate, neither lobed nor toothed: fls. solitary, the petals and sepals greenish, the corona white, with zones of red-purple: fr. as grown in S. Calif. described as oval, larger and more oblong than that of *P. edulis*, with a hard shell and buff-brown in color. Trop. Amer. B.M. 2967.—Young foliage has metallic hues.

BB. Bracts free.

c. Tube of fl. evident and cylindrical, swollen at the base.

8. *racemosa*, Brot. (*P. princeps*, Hort. *P. amabilis*, Hort., in part). Lvs. glabrous, usually truncate at base, mostly deeply 3-lobed, the margins entire: fls. 4 in. or more across, the narrow petals deep red and wide-spreading, the short, upright crown purplish; calyx keeled on the lower side; fls. solitary, but the peduncles usually 2 from an axil, becoming racemose on the ends of the shoots: bracts 3: fr. described in cult. as cylindrical-ovate, greenish yellow at maturity. Brazil. B.M. 2001. B.R. 285. L.B.C. 1:84. Gn. 39:168. G.L. 24:222.—A fine old species and a parent of various garden hybrids. One of the best of the red-fl. *passifloras*. Summer and fall.

9. *Raddiana*, DC. (*P. kermesina*, Link & Otto). Rather slender climber, glabrous: lvs. shallow-cordate, 3-lobed and sparingly dentate, purplish beneath: fls. solitary, with very narrow distinct sepals and petals of a bright crimson-red, which are wide-spreading at first but finally turning almost straight back; crown black-purple, upright, with smaller whitish filaments inside. Summer and fall. Brazil. B.M. 3503. B.R. 1633. G. 1:453. F.W. 1874:161.—An old and well-known species; said to prop. from cuttings of old well-formed wood. *P. Loudonii*, Hort., is considered to be a hybrid of this and *P. racemosa*.

10. *Watsoniana*, Mast. Sts. wiry, purplish, with leafy dentate stipules: lvs. shallow-cordate, rather broader than long, 3-lobed to the middle, with a few teeth: peduncles 1-fl.; fls. about 3 in. across, the sepals linear and shaded with violet; petals also very narrow, lilac; crown of many rows of filaments, violet with bars of white below the middle, the inner and shorter set

deep violet. Probably Brazilian. G.C. II. 26:648, 649. I.H. 36:74. Gn. 33:194. A.F. 6:571.—Good grower.

cc. Tube of fl. very short, thick or fleshy in substance.

d. Sts. and branches strongly 4-angled or even winged: lvs. simple.

11. *quadrangularis*, Linn. GRANADILLA. Fig. 2770. Tall strong climber, glabrous: lvs. ovate or round-ovate,

2771. *Passiflora edulis*. ($\times \frac{1}{4}$)

cordate at base, mucronate, entire, the petiole with 2 or 3 pairs of glands: stipules large: fl. large (3–5 in. across) and interesting, fragrant, with ovate sepals and petals (the former

white within and the latter reddish), the crown composed of 5 series of white-and-purple colored filaments, of which the outermost exceed the floral envelopes: fr. oblong, 5–9 in. long, yellowish green, pulpy and edible. Trop. Amer. B.R. 14. R.H. 1898, p. 569. Gn. 51, p. 313; 59, pp. 4, 7. G. 33:161.—Widely grown in the tropics, and variable, both as a vine and for its edible frs. Frequent in collections of economic plants in the N. It is a good climber for covering a greenhouse roof. Best results are secured if the temperature does not fall below 50°. The fr. ripens in summer. The fls. usually need to be hand-pollinated if fr. is wanted on house-grown plants. Var. *variegata*, Hort. (*P. variegata*, Hort. *P. aucubifolia*, Hort.), has foliage blotched with yellow.

12. *alata*, Dry. St. winged: lvs. glabrous, oval to ovate, somewhat cordate at base, the margin often undulate but otherwise entire, the petiole with 2 pairs of glands: fl. 3–4 in. across, very fragrant, the interior of the sepals and petals carmine; corona nearly or quite as long as the envelopes, the numerous filaments part-colored with red, purple, and white: fr. yellow, ovoid-pointed, about 5 in. long, very fragrant and one of the most edible. S. Amer. B.M. 66. G.C. III. 15:19; 22:449–51; 43:187. R.B. 20, p. 104 (see R.H. 1902, pp. 287–9, for taxonomic discussion).—An excellent old species, ripening its fr. in midsummer. It is very variable, and is perhaps one form of a polymorphous species including the *granadilla*. *P. phænicea*, Lindl. (B.R. 1603), *P. brasiliensis*, Desf., *P. oviformis*, Roem., *P. latifolia*, DC., *P. mauritiana*, Thouars, and *P. mascarensis*, Presl., are all considered to be forms of this species. *P. Lawsoniana*, Hort., not Mast., is a hybrid of *P. alata* and *P. racemosa*: lvs. oblong-oval, somewhat peltate, entire: fls. 3–4 in. across, brownish inside, the corona with filaments in several series.

13. *Decaisneana*, Hort., is perhaps a hybrid of *P. quadrangularis* and *P. alata*: fls. bright carmine inside, about 4 in. across; corona as long as or longer than the

envelopes, the more or less tortuous filaments banded with deep blue and white: lvs. bearing about 6 glands. R.H. 1855:281; 1902:288 (as *P. Decaisneana* and *P. quadrangularis* var. *Decaisneana*, where a botanical and historical discussion by André may be found). F.S. 8:848.

DD. Sts. and branches terete, or at least not winged.

E. Lvs. not lobed.

14. *amabilis*, Hook. St. slender and terete: lvs. ovate, very sharp-pointed, entire, rather thin, the petiole with about 2 pairs of glands: fl. solitary, about 3 in. across, the sepals and petals alike and bright brick-red within; corona or white filaments in 4 series, the 2 inner series being short. Brazil. B.M. 4406. Gn. 55:272.

15. *laurifolia*, Linn. (*P. tinifolia*, Juss.). JAMAICA HONEYSUCKLE. WATER-LEMON. St. terete, plant glabrous: lvs. oval to oval-oblong, thickish, entire, with

2772. *Passiflora carulea*, the commonest cultivated passion-flower. ($\times \frac{3}{4}$)

a short sharp point; petiole with 2 glands at apex: fl. about $2\frac{1}{2}$ in. across, white, with red spots or blotches; corona somewhat exceeding the petals or at least about equaling them, in 3 series, violet with white bands: fr. about 3 in. long, yellow, spotted with white, edible, according to Lindley, but the plant cult. under this name in S. Calif. said to have frs. not yellow spotted white, but much like those of the plant there known as *P. ligularis* (see No. 7). Trop. Amer. B.R. 13. B.M. 4958.

16. *coccinea*, Aubl. (*P. velutina*, DC. *P. fulgens*, Wallis). Glabrous: lvs. ovate and coarsely toothed; petioles with 2-3 pairs of glands: fl. scarlet; corona orange: fr. pulpy, edible. S. Amer. G. 28:512. H.F. II. 6:6.—A free-flowering species, of good constitution.

EE. Lvs. 3-7-lobed.

F. Blossoms bright red.

17. *vitifolia*, HBK. (*P. sanguinea*, Smith. *Tacsônia Buchananii*, Lem.). St. shrubby, climbing, terete: lvs. cordate-ovate in outline, deeply 3-lobed or divided

and the divisions coarsely toothed, strong-veined, usually pubescent beneath: fl. 4-6 in. across, nearly flat, the linear-oblong sepals and petals bright scarlet, the sepals with a spine at the tip; outer corona filaments red, the inner ones white, all of them upright or spreading and much shorter than the envelopes. Brazil. B.M. 7936. F.M. 1878:317. G.C. III. 8:213; 43:187. G.Z. 28:145. F.W. 1868:289.—An old species, but not common in cult. Said not to be free-flowering. A very brilliant species.

FF. Blossoms white, greenish, purplish, or variously tinted, but not red.

G. Rays of corona (or the outer ones) about as long as the floral envelopes: lf.-margins strongly serrate (except sometimes in No. 20).

18. *incarnata*, Linn. WILD PASSION-FLOWER. MAY-POP. Fig. 2768. Tall-climbing strong perennial vine, glabrous or nearly so, becoming 20-30 ft. long: lvs. 3-lobed to about half their depth, broadly cordate-ovate in outline, serrate, the petiole bearing 2 glands near the top: fl. axillary and solitary, about 2 in. across, white, with a light purple corona band at its center: fr. oblong, about 2 in. long, with 3 sutures, yellow when ripe, edible. Dry places, Va., south and west. B.M. 3697. Mn. 9:17.—A weedy plant, but offered by dealers in native plants. With protection, the roots will survive the winter as far north as Baltimore, and the strong herbaceous vines make a fine cover for arbors and verandas. Easily grown from seeds.

19. *edulis*, Sims. Fig. 2771. More woody and stronger: lvs. large, deeply 3-lobed and serrate: fl. white, often tinted with purple, the rays nearly as long as the envelopes, white for the upper half but purple at the base: fr. globular-oblong, thickly purple-dotted when ripe, the rind hard. Brazil. B.M. 1989. R.H. 1857, p. 224; 1883, p. 489. Gn. 50:414; 62, p. 259. G.C. III. 23:101. A.G. 13:120.—Runs into several forms. The fr. is fragrant and edible, but there is little pulp, the seeds occupying most of the interior. Readily grown from seeds. Naturalized in tropical countries.

20. *pruinosa*, Mast. Climbing, the sts. terete, glabrous: lvs. broad in outline, 3-lobed beyond the middle, the lateral lobes diverging, the margins remotely glandular-toothed, glaucous beneath: stipules very large and lf.-like, cordate, 2 in. long: fls. 3 in. across, pale or pearly violet, the corona of numerous filaments, the outermost of which are nearly as long as the petals and are deep violet at the base, yellowish in the middle and curly at the top. British Guiana. G.C. III. 22:393 (desc.).—First described in 1897.

GG. Rays distinctly shorter than envelopes: lf.-margins nearly or quite entire.

21. *alba*, Link & Otto (*P. atomaria*, Planch.). St. terete: stipules very large and lf.-like: lvs. broad-ovate and somewhat cordate, rather shallowly 3-lobed, glaucous beneath, the margins entire: peduncles exceeding the lvs., 1-fl.; fl. little more than 2 in. across, clear white: fr. obovoid, the size of an egg, green at first, but becoming yellowish. Mex. to S. Amer. G.C. II. 19:693. R.H. 1883, p. 201; 1884:36. G.W. 14, p. 151.

22. *adenophylla*, Mast. By some thought to be probably identical with *P. alba*: lvs. glabrous, cordate at base, 3-lobed nearly to middle, glandular in the sinus, the lobes oblong and apiculate; petiole with sessile glands: fls. white, the peduncle equaling or exceeding the petiole; sepals bearing a subulate appendage near apex on the back; petals shorter than sepals and narrower. Mex.

23. *violacea*, Vell. Tall, glabrous, with drooping branches: lvs. straight at base and somewhat peltate, with 3 long, narrow lobes, of which the side ones stand at nearly right angles to the central one, the margins

entire or with a few teeth in the bottom of the sinus, the under surface slightly glaucous: fl. about 3 in. across, the petals and sepals lilac-pink inside (sepals ending in a long spur), the numerous filaments of the corona

2773. *Passiflora (Tacsonia) Van Volxemii*. Central leaflet broader than common. ($\times \frac{1}{2}$)

white-tipped and barred with violet and white. Brazil. B.M. 6997. R.H. 1885:468. G.W. 14, p. 151.

24. *cærulea*, Linn. Fig. 2772. Slender, but a strong grower, glabrous and somewhat glaucous: lvs. divided nearly to the petiole into 5 lanceolate or lance-elliptic entire sharp-pointed segms. of which the 2 lower ones are sometimes again lobed: fl. 3-4 in. across, slightly fragrant, greenish white, the sepals tipped with a short point, the rays of the corona in 2 series, blue at the tip, white in the middle and purple at the base, the styles light purple. Brazil. B.M. 28. Gn. 31, p. 421; 34, p. 114; 46, p. 369. G. 3:611. J.H. III. 47:57.—The commonest of passion-flowers in American greenhouses, and now represented by several named forms and hybrids. It can be grown in the open in the S. and in Calif. as far north as San Francisco. Var. *grandiflora*, Hort., is only a somewhat larger-fl. form. Constance Elliott (*P. cærulea* var. *alba*), is a white-fl. fragrant form. G.C. III. 43:186. Gn. 31:420. There are hybrids with *P. Raddiana*, *P. racemosa*, *P. alata*, and others. *P. cærulea* grows readily from seeds.

II. *TACSONIA*, the hypanthium or calyx-tube long ($\frac{1}{2}$ in. long and usually much more).

A. Fls. orange or rosy orange.

25. *Párritæ*, Bailey (*Tacsonia Párritæ*, Mast.). Lvs. deeply 3-lobed, glabrous above, pilose beneath, lobes narrow and entire; stipules entire, subulate-acuminate:

fl. with a long and slender tube, glabrous, swollen at the base; sepals winged and with points, rosy-orange; petals oblong and flat, shorter than the sepals, orange; corona double, the outer row of tooth-like projections. Colombia. G.C. II. 17:225. I.H. 35:41.—Named for Senor Parra ("better known as Parrita"), through whom it was intro.

AA. Fls. scarlet or rose-colored.

B. Bracts beneath the fl. not united.

C. Lvs. simple or not lobed.

26. *insignis*, Hook. (*Tacsonia insignis*, Mast.). Pilose: lvs. ovate-lanceolate, subcordate, dentate, rugose or blistered above and red-downy beneath, the stipules dissected: fl. about 6 in. across, violet, rose or crimson; tube cylindrical, swollen at the base, downy; sepals about twice longer than the tube, lance-oblong, spurred at the end; petals similar in shape, obtuse; corona of one series of short threads, blue and white. Probably Peruvian. G.C. 1873:1113. F.S. 20:2083, 2084. B.M. 6069.

CC. Lvs. 3-lobed or divided.

D. Foliage glabrous at maturity.

27. *Van Vólxemii*, Triana & Planch. (*Tacsonia Van Vólxemii*, Hook.). Fig. 2773. Sts. slender and slightly pubescent: lvs. cordate-ovate in outline, deeply 3-lobed, the lobes long-lanceolate-acuminate, serrate: fls. 5-7 in. across, bright red with short green calyx-tube that has a swollen base, the acute calyx-lobes green externally; corona an inconspicuous toothed rim. Colombia. B.M. 5571. G.C. 1866:171. G.Z. 9:144.—Less showy than some others, but a well-known species.

28. *Jámesonii*, Bailey (*Tacsonia Jámesonii*, Mast.). Lvs. suborbicular, 3-lobed, glabrous: fl. large, bright rose or coral-red, with a cylindrical tube 4 in. long: fr. said to be green at maturity, oval. Peru.

DD. Foliage downy beneath at maturity.

29. *exoniensis*, Hort. (hybrid of *P. Van Vólxemii* and *P. mollissima*). Fig. 2774. Lvs. downy, cordate, ovate-oblong, divided nearly to base into 3 lanceolate, serrate segms.: fls. $4\frac{1}{2}$ -5 in. across; sepals brick-red outside, brilliant rose-pink within; throat violet; tube white inside, $2\frac{1}{2}$ in. long. Resembles *P. Van Vólxemii* in having peduncles as long as lvs., linear stipules, free downy bracts, filamentous corona near base of tube

2774. *Passiflora (Tacsonia) exoniensis*. ($\times \frac{1}{4}$)

and violet color of throat. Resembles *P. mollissima* in having downy lvs., long flower-tube, color of fl. and aristate sepals.

BB. Bracts beneath the fl. more or less united.

c. Lf.-lobes short, obtuse or nearly so.

30. *manicata*, Pers. (*P. ignea*, Hort. *Tacsônia manicata*, Juss.). RED PASSION-VINE. Fig. 2775. St. nearly terete, finely pale-pubescent: lvs. coriaceous, 3-lobed to about the middle, finely serrate, the lobes broad-oblong, pale beneath; stipules ovate, 1 in. across, notched, clasping: fls. solitary on slender axillary peduncles, brilliant scarlet, 4 in. across; perianth-tube $\frac{1}{2}$ in. long, inflated and 10-ribbed at base; outer corona of many short blue filaments, some of which surround the column; inner corona of an inflexed membrane: fr. egg-shaped or almost globular, yellow-green, the skin thick; seeds many in a thin pulp. Colombia, Ecuador, and Peru. B.M. 6129. G.F. 7:265 (from which Fig. 2775 is reduced). R.H. 1903:356.—This plant seems to be grown with difficulty in greenhouses, but it is at home in the open in S. Calif., climbing into the tops of trees and blooming profusely, making a brilliant display. It grows with great vigor and rapidity, renewing itself freely from seeds.

cc. Lf.-lobes long-acute.

31. *mixta*, Linn. f. (*Tacsônia mixta*, Juss. *T. erinantha*, Benth.). Glabrous or somewhat pubescent: lvs. orbicular-ovate, thick, 3-lobed to the middle, the lobes long-acute and serrate: fl. 3-4 in. across, rose-pink, the oblong sepals not equaling the green scarcely saccate tube; corona a short multiple rim or disk. Andes.—It is reported that the *P. mixta* that has been grown in Calif. is *P. mollissima*.

32. *mollissima*, Bailey (*Tacsônia mollissima*, HBK.). Pubescent: lvs. cordate-ovate in outline, very pubescent beneath, the lobes extending nearly to the base of the blade and ovate-lanceolate in shape and serrate, the stipules lacinate: fl. about 3 in. across, rose-color, the green tube exceeding the sepals and swollen at the base; corona a short rim. Andes. B.M. 4187. B.R. 32:11. F.S. 2:78. G. 28:17.—*P. tubiflora*, offered about 20 years ago in Calif. (and now apparently lost) is said not to differ much from *P. mollissima*.

33. *Smythiana*, Hort. Seedling of *P. mollissima* or hybrid with it, with very brilliant orange-scarlet or rosy-crimson fls. G.C. III. 12:705. Gn.W. 8:149.

P. alata-cerulea (*P. Pfordtii*, Hort.) is a hybrid from seed of *P. alata* by pollen of *P. cerulea*: lvs. much like those of *P. alata*, 3-lobed: fls. fragrant, beautiful; sepals white; petals pink; corona of 3 series, the outer filaments being white at tip, blue-purple in the middle, and black-purple at the base. B.R. 848. R.H. 1847:121.—*P. albo-nigra*, Hort. Said to be a hybrid of *P. alata* and *P. Raddiana*: lvs. 5-lobed: petals white; corona white above and blackish purple below. Gt. 1:68.—*P. Allardii*, Hort.—*P. quadrangularis* × *P. cerulea* Constance Elliott, raised by Mr. Allard of the Botanic Garden, Cambridge, England: lvs. usually with 3 broad lobes: free-flowering; petals white shaded pink; corona deep cobalt-blue.—*P. ambigua*, Hemsl. Possibly a hybrid of *P. laurifolia* and *P. maliformis*: fls. more than double the size of *P. laurifolia* (5 in. diam., pink and purple): petiole biglandular in middle: lf.-blades attenuate at base; stipules linear. Nicaragua. B.M. 7822. G.C. III. 31:171.—*P. atropurpurea*, Hort. Hybrid: has foliage of *P. racemosa*, but infl. and fl. in general shape more like *P. Raddiana*: fls. about 3 in. diam., tube less than $\frac{1}{2}$ in. long; sepals deeply keeled, reddish-violet or prune-colored; petals about length of sepals, dark blood-red; outer corona violet spotted white, the filaments or threads half the length of the petals; inner corona shorter, violet, each thread enlarged at top. G. 26:495.—*P. Belottii*, Hort. Sepals flesh-colored; petals rose, corona blue. Thought to be a hybrid of French origin, having been received in England about 1847.—*P. Bournaparteae*, Hort., hybrid of *P. alata* and *P. quadrangularis*, "possessing the sweet-scented and richly colored fls. of the former with the handsome foliage of the latter:" blooms freely when young: fls. solitary in the axils, reddish-crimson, the corona of rich red, white, and blue filaments. J.H. III. 51:253.—*P. capsularis*, Linn. Tall slender pubescent climber with red tendrils: lvs. with 2 lunate ovate-oblong lobes: fls. solitary, 2 in. across, rose-red; calyx-tube $\frac{1}{2}$ in. long, cylindrical, the sepals narrowly linear-oblong and obtuse; petals narrower and paler; outer corona much shorter than petals, white; inner corona, short and incurved, white; ovary hairy. Brazil. B.M. 7751 (not 2868, which is *P. rubra*).—*P. chelidonea*, Mast. Lvs. oblong, forked at the end to

one-fourth the length and with a small middle lobe, marked with dots: fl. 2 in. across, greenish, with a folded corona. Ecuador. G.C. II. 12:40.—*P. cinnabarina*, Lindl. Branches terete: lvs. broad-ovate, 3-lobed, margins entire: fls. solitary, $2\frac{1}{2}$ in. across, red; corona short, folded, yellowish. Austral. G.C. 1855:724. B.M. 5911.—*P. colimensis*, Mast. & Rose. A Mexican species first described in 1899, but cult. for several years in Washington. It is an herbaceous species, with shallow-lobed obtuse denticulate lvs. and small whitish blue-marked fls. on single peduncles. Promising as an outdoor climber.—*P. eucophylla*, Mast. Lvs. oblong, very broad, rounded and biglandular at base, 2-lobed at apex with small lobe between, upper surface dull green and lower surface purplish: fls. whitish, not specially attractive. British Guiana.—*P. fatida*, Linn. (*P. hirsuta* and *P. hircina*, Hort.). Allied to *P. adenopoda*: annual or sometimes perennial: lvs. pubescent, 3-lobed, the margins entire or obscurely angled: fls. whitish, small, the corona as long as the petals and colored purple and blue: fl.-bracts pinnatifid. Trop. Amer. L.B.C. 2:138. B.M. 3635, the form known as var. *nigelliflora*, Mast.; and 288, the var. *ciliata*, Mast. Perhaps in cult., but apparently not offered in the trade. Variable.—*P. galbana*, Mast. Sts. terete: lvs. lance-oblong, short-petioled, entire: stipules

2775. *Passiflora manicata*. (× about $\frac{1}{3}$)

ovate-pointed: fl. solitary on a long peduncle, 3 in. across, greenish yellow, the sepals and petals very narrow, the not folded corona short. Brazil. G.C. III. 20:555.—*P. Imthurnii*, Mast. Lvs. broad, oblong, acute, entire, thick, glabrous above, but not beneath: fl. erect, 4-5 in. across, brilliant scarlet and rose-color, with white in the center; corona very short. British Guiana. G.C. III. 23:307. Very showy.—*P. kewensis*, Hort. "It is a cross raised by Mr. Watson, the assistant curator, between the hardy *Passiflora cerulea* and the Brazilian *P. Raddiana*. The fls. are larger than those of *P. Raddiana*, the petals and fringe longer, while the color is carmine suffused with blue, which, though perhaps not so bright and pleasing as it is in the parent, is a lovely color."—*P. macrocarpa*, Mast. Of the *P. quadrangularis* group: st. 4-angled, strong-climbing: lvs. oval, obtuse: fl. white and purple: fr. as large as a small melon, weighing several pounds. Brazil.—*P. maliformis*, Linn. Of the *granadilla* section: st. described as cylindrical: lvs. ovate or ovate-oblong, entire, the petiole 2-glandular: fl. fragrant, large; petals white; corona blue: fr. yellow, round, and smooth, 2 in. diam., with agreeable pulp. W. Indies to S. Amer.—*P. Miersii*, Mast. Sts. slender and wiry: lvs. lance-ovate and entire, claret-colored beneath: fl. 2 in. across, white, shaded with pink, the corona half the length of the petals, white, barred with purple. Brazil. G.C. III. 4:353.—*P. militaris*, Hort. (*Tacsonia militaris*, Hort.). A showy winter-bloomer intro. from the Transvaal, supposed to be a hybrid of *P. manicata* × *P. insignis* or *P. Van Volxemii* × *P. insignis*: lvs. green and glabrous above, hairy beneath, deeply 3-lobed and sharp-serrate: fls. bright crimson taking on purplish tinge with age, 4-5 in. across, on hairy stalks 5 in. long; tube short, as in *P. manicata*, glabrous, inflated at base; outer calyx-lobes striped on outside, green in center, dull crimson on margins; corona small, purple; bracts 3 at base of tube, ovate, serrate.—*P. penduliflora*, Bert. Lvs. very broad, slightly 3-lobed: fls. yellow and green, solitary or twin, often pendulous; corona in 1 series and 12-

14-parted. W. Indies. B.M. 4565. J.F. 2:114.—*P. pinnatistipula*, Cav. (Tacsonia pinnatistipula, Juss.). Resembles *T. mollissima*, but the bracts are free; stipules pinnatisect; fls. rose-colored. Chile. B.M. 4062. B.R. 1536.—*P. punctata*, Linn. Herbaceous climber, minutely puberulous; lvs. nearly semi-circular or almost lunate, shallowly 3-lobed, the middle lobe much smaller, variegated on both surfaces with purple; fls. in pairs, pale yellow, about $1\frac{1}{2}$ in. across; sepals ovate-oblong, obtuse, nearly $\frac{3}{4}$ in. long; petals similar but much shorter; corona in 3 rows, yellow, the filaments of the outer row with violet heads. S. Amer. B.M. 8101.—*P. quadrilamellata*, Rodschied. Fls. solitary, 4-5 in. diam., rose-color with a darker shade in the center; corona with an outer ring of dark red filaments: inner filaments tubular and paler; sepals and petals much alike, very long and narrow, acuminate-pointed. Habitat unknown. G. 28:575.—*P. serratifolia*, Linn. Lvs. ovate-lanceolate, acute, serrulate, pubescent beneath; petiole 4-glandular: fls. purple; corona pale purple and bluish. Mex. B.M. 651. H.U. 2, p. 71.—*P. suberosa*, Linn. Glabrescent, with corky bark: lvs. roundish or ovate, 3-lobed, the lobes ovate to oblong to lanceolate, the petiole 2-glandular above the middle: fls. greenish yellow, without petals; corona short: berry ovoid, small. W. Indies, Venezuela, etc.—*P. triloba*, Ruiz & Pav. Lvs. large, cordate-ovate, 3-lobed or entire: fl. 3 in. across, with violet reflexed sepals and petals, and a long cuplike corona, with filaments banded white and purple. Peru. I.H. 36:83.—*P. Weberiana*, André. Glandular-hairy: lvs. large, 3-lobed, the margin usually toothed: fl. solitary, 2 in. across, white, the corona banded with white: fr. setose, purple. Argentina. R.H. 1887:324.

L. H. B.

PASTINACA (name from the Latin *pastus*, food). *Umbelliferae*. About a dozen species of tall herbs native to Eu. and Asia, by Bentham & Hooker united with the genus *Peucedanum*, but by Engler & Prantl and others kept distinct. It is distinguished from *Heracleum* and *Peucedanum* by technical characters of the fr. Fls. yellow, small, in compound naked umbels; calyx-teeth obsolete. *Pastinaca* is known to horticulturists in the parsnip (which see), *P. sativa*, Linn. It is a native of Eu., but is now grown in cool-temperate countries for its large edible root. In deep moist soil and a cool climate, the roots become 18-20 in. long and 4 in. or more in diam. at the crown. It was cult. before the Christian era. It has run wild from gardens, often becoming a bad weed in neglected fields and on roadsides. *P. sativa* is a robust biennial, sending up a grooved st. (which becomes hollow) 3-5 ft.: lvs. odd-pinnate, with 3-4 pairs of sessile ovate or oblong sharp-toothed and notched lfts. the terminal lft. 3-lobed: fr. ("seed") thin and flat, retaining its vitality only a year or two. When run wild, it loses its thick root, and sometimes it becomes annual.

L. H. B.

PATERSÖNIA (named for William Paterson, an English traveler). *Iridaceae*. Perennial herbs with short creeping rhizomes and rigid linear lvs. grouped in a distichous basal rosette: perianth-tube elongated; outer segms. obovate-cuneate, spreading; inner minute, erect; ovary clavate, 3-celled; ovules many, superposed; seeds angled by pressure.—About 19 species, all natives of Austral. *P. occidentalis*, R. Br. (*P. sapphirina*, Lindl.). Sts. very short: lvs. rigid, longest often over 1 ft.: scapes longer or shorter than lvs., dilated and striate under the spike; outer bracts $1\frac{1}{2}$ in. long or more, prominently or rather obscurely keeled, inner bracts membranaceous, sometimes pubescent on the keel: fls. usually numerous; perianth-tube more or less villous; outer segms. often fully 1 in. long, broad and very obtuse, rich blue; inner segms. minute, ovate or lanceolate; style articulate near the base of the anthers. H.U. 1, p. 324.

PATRÍNIA (E. L. Patrín, 1742-1814, French traveler in Siberia). *Valerianaceae*. Yellow- or white-flowered valerian-like hardy herbaceous perennials, a foot or so high, blooming in early summer; resemble *Valeriana* and *Fedia*.

Glabrous or loosely villous herbs: lvs. once or twice pinnatifid or pinnatisect, the radical ones rarely entire: cymes corymbose-panicled; bracts narrow, free, but sometimes appendaged with a large 2-nerved and netted-veined bracteole which is appressed to the fr.: calyx with a small erect or spreading somewhat dentate limb; corolla-tube very short; lobes 5, spreading;

stamens usually 4; style nearly entire at apex: sterile locules of the fr. nearly as large or larger than the fertile ones.—About 15 species in extratropical Asia; little planted. They are of easy cult. in damp or shady places; bloom May to July. They are grown either in borders or in rockwork. Prop. by division of the roots and also by seeds.

scabiosæfolia, Fisch. St. glabrous: radical lvs. ovate or oblong, incised-serrate and lyrate; cauline lvs. pinnatifid, the lobes lanceolate-linear, acute, terminal one longest: fls. yellow; corymb loosely subpaniculate: fr. 3-cornered. Dahuria. L.B.C. 14:1340.

villösa, Juss. Coarse, 2-3 ft.: radical lvs. villous, petiolate, auricled; cauline lvs. sessile, dentate: corymb panicled, bearing white fls. Japan.

triloba, Miq. (*P. palmata*, Maxim.). Sts. erect, reddish, 8-16 in., simple below, pubescent at nodes and also on peduncles: lvs. cordate in outline, deeply palmately 3-5-lobed or the uppermost little if any lobed, margins coarsely toothed: fls. golden yellow, fragrant, in 3-branched cymes; corolla tubular, about $\frac{1}{2}$ in. long. Japan. B.M. 8328. G.C. III. 46:244; same cult. in III. 52:55.—Useful in rock-garden work. The lvs. are mostly at the base of the plant, the fl.-sts. rising about 4 in. above them; fl.-clusters 3-4 in. across.

gibbosa, Maxim. Differs from *P. triloba* in smaller fls., rather larger not cordate lvs. and st. not leafy: about 9 in. high: lvs. mostly radical and crowded, long-petioled, suborbicular, the upper ones round-ovate to ovate, acuminate, the base truncate or perhaps subcordate, pinnately lobed, the lobes incised-serrate: fls. yellow, the corolla distinctly gibbous at base; clusters flat: lvs. more or less blistered. Japan.

P. intermedia, Roem. & Schult. (*P. rupestris*, Bunge. *Fedia rupestris*, Hort.). 1-1½ ft.: lvs. pinnatifid, the segms. lanceolate with large terminal lobe: fls. yellow, fragrant, in May and June. Siberia. B.M. 714 (as *V. sibirica*).—*P. sibirica*, Juss. (*Valeriana sibirica*, Linn.). 1 ft., most of the lvs. radical, the cauline ones pinnate with entire segms., the radical long-spatulate, serrate, strong-toothed or entire (even on same plant): fls. yellow, fragrant. Siberia. B.M. 2325 (as *V. ruthenica*).

L. H. B.

PAULLÍNIA (probably after Simon Paulli, 1608-1680, professor of anatomy, surgery, and botany at Copenhagen). *Sapindaceae*. One species is a greenhouse climber, which may also be grown as an upright fern-like pot-plant.

Twining shrubs: lvs. alternate, stipulate, compound, 1-3-ternate or pinnate, or decomposed; petiole often winged; lfts. usually dentate, dotted or minutely lined: racemes axillary, usually with 2 tendrils; fls. whitish or pale, small; sepals 5, the 2 upper larger, connate; petals 4, but there is a fifth abortive one, two of the petals smaller and bearing a scale below the apex; stamens 8; ovary 3-celled, bearing a 3-parted style. Trop. Amer., and sparingly in Afr.; species about 140. Distinguished from allied genera, as *Cardiospermum*, by the septicidal fr., which is often pear-shaped. *P. thalictroides* is a handsome stove foliage plant, with much divided lvs. somewhat resembling a rue, maidenhair, or *davallia*. The fls. are inconspicuous, pinkish and borne in autumn. Forty to fifty years ago, when the interest in foliage plants was at its height, this plant was widely distributed. It used to be trained to a trellis for exhibition or grown on the pillars and rafters of hothouses. It is now a rare but choice plant for clothing the tops of unsightly tubs in which palms are growing. It is also excellent for large vases and stands the sun well. The young lvs. have a pretty bronze tint unless they are shaded too much. The plant is prop. by cuttings of young shoots taken in early spring. If the tops are pinched, the young plants will branch out and make handsome specimens in 4- or 5-in. pots.

thalictroides, Juss. Lvs. 4-10 in. long, triangular in outline, 3-ternately-pinnate; pinnæ in 6-8 pairs; pinnales 4-8 pairs, 4-8 lines long: fls. inconspicuous, pink-

ish. Brazil. B.M. 5879. Gn. 51, p. 160. F. 1873, p. 124. J.H. III. 46:99. G. 7:153; 19:650. G.M. 46:397. Var. *argentea*, Hort., has foliage suffused silvery gray. L. H. B.

PAULOWNIA (after Anna Paulowna, princess of the Netherlands). *Scrophulariaceæ*. Ornamental trees, grown for their beautiful flowers in showy panicles and for their large handsome foliage.

Deciduous, rarely half-evergreen: lvs. opposite, long-petioled, entire or sometimes 3-lobed or coarsely toothed, without stipules: fls. in terminal panicles; calyx campanulate, 5-lobed; corolla with long slightly curved tube, and spreading oblique 5-lobed limb; stamens 4: fr. a 2-celled caps., loculicidally dehiscent, with numerous small winged seeds.—About 8 species in China; in Japan only cult.

The paulownias are medium-sized or fairly large trees with stout spreading branches, large long-petioled leaves similar to those of catalpa, and violet or nearly white large flowers resembling those of the foxglove or gloxinia in shape, appearing in terminal panicles before or with the leaves and followed by ovoid pods remaining on the tree and conspicuous during the winter. *P. tomentosa* is fairly hardy in sheltered positions as far

2776. *Paulownia tomentosa*, showing verdurous growth of the young shoots.

north as Massachusetts, but the flower-buds are usually killed in winter, and it does not flower regularly north of New York City; plants raised from seed collected in Korea have proved hardier at the Arnold Arboretum than the commonly cultivated Japanese plant, also the var. *lanata* from Central China seems to be somewhat hardier. As an ornamental foliage plant it may be grown as far north as Montreal, where it is killed to the ground every winter, but throws up from the root vigorous shoots attaining 10 to 14 feet, with leaves over 1 foot and occasionally even 2 feet long. If used as a foliage plant and cut back to the ground every spring, the young shoots should be removed, except one or very few on each plant; during the first years of this treatment they will grow more vigorous every year, but afterward they will decrease in size, weakened by the continuous cutting back; they should then be replaced by strong young plants. Where the flower-buds which are formed the previous year are not killed by frost, the paulownia is one of the most conspicuous flowering trees in spring, and in summer the foliage, although it is of somewhat dull color, attracts attention by the size of the leaves. In temperate climates it is sometimes used as an avenue tree. It thrives best in a light deep

loam, and in a sheltered position. The other species are still little known in cultivation and are probably tenderer; they are great favorites with the Chinese and much planted in central and southern China. Propagation is by seeds sown in spring or by root-cuttings, and by greenwood cuttings under glass; it may be grown also from leaf-cuttings; the young unfolding leaves when about 1 inch long are cut off close to the stems and inserted in sand under a hand-glass in the propagating-house.

Paulownia tomentosa in southern California reaches a height of 40 feet in twenty-five years, with a spread nearly as great. When in full leaf it makes a dense shade. It starts to bloom before the leaves come and all is over before the tree is in full leaf. For this reason it is not a favorite. The jacaranda is a prettier blue, more floriferous, lasts three times as long, the blooms continuing until the tree is in full leaf. It is out of leaf not more than half as long as is paulownia and in mild winters holds much of its foliage throughout, being properly an evergreen. It makes as dense shade as the paulownia, has a prettier leaf and is more desirable in every way. The growth of the two trees is about the same at the end of a quarter century. The habit of the paulownia in retaining dry seed-pods on dead limbs 3 or 4 feet long is very unpleasant, and necessitates a thorough cleaning each year to the tip end of the uppermost branch—often a hard task to accomplish. (Ernest Brauntton.)

tomentosa, Steud. (*P. imperialis*, Sieb. & Zucc.). Fig. 2776. Tree, to 40 ft., with stout spreading branches forming a round or ovate head: lvs. rather long-petioled, broadly cordate-ovate, entire or sometimes 3-lobed, acuminate, pubescent above, tomentose beneath, 5-8 in. long or on vigorous shoots even larger: panicles to 10 in. long; fls. fragrant, pale violet, $1\frac{1}{2}$ –2 in. long; pedicels and calyx densely rusty tomentose; calyx-lobes short, rounded: caps. woody, broadly ovoid, pointed, 1 in. or somewhat longer. April, May. Cent. China, cult. in Japan. S.Z. 1:10. B.M. 4666. P.M. 10:7. Gn. 34, p. 79; 54, p. 476; 60, p. 130. G.C. III. 48:277; 51:430, 431. S.I.F. 1:85. H.U. 4, p. 102. R.H. 1907, p. 378. G. 35:769. Mn. 7, p. 171.—It is sometimes escaped from cult. in the southern states. Var. *pallida*, Schneid. (*P. imperialis* var. *pallida*, Dode). Fls. pale or whitish violet: lvs. dull green above. Var. *lanata*, Schneid. (*P. imperialis* var. *lanata*, Dode). Lvs. more densely yellowish tomentose beneath: calyx more tomentose with longer acutish lobes. Cent. China.

P. DuRoiuxii, Dode. Tree, to 60 ft.: lvs. oblong-ovate, with open sinus at the base, tomentose below, to 1 ft. long: fls. about 3 in. long, pale lavender-purple, not spotted; calyx with acute tomentose lobes and glabrous or glabrescent tube; corolla rather gradually narrowed toward the base. Cent. and S. W. China.—*P. Fürstii*, Franch. Tree, to 60 ft.: branchlets usually pilose: lvs. pubescent or glandular above, slightly pubescent beneath, entire or with few coarse teeth: fls. lavender or whitish, $2\frac{1}{2}$ in. long; calyx tomentose outside with triangular acutish lobes. W. China.—*P. Fortunei*, Hemsl. Tree, to 20 ft.: lvs. sub-coriaceous, densely tomentose below, ovate or ovate-oblong, to 10 in. long: fls. to 4 in. long, white, spotted purple inside; calyx 1 in. long, glabrous outside except the acutish lobes; corolla rather gradually narrowed toward the base. S. E. China.—*P. Sibthorpii*, Pampanini & Bonat. Small tree: lvs. densely brown-woolly, narrow, deeply cordate, 3–5 in. long: fls. in leafy panicles, sky-blue; calyx densely tomentose, with oblong obtusish lobes. Cent. China.—*P. thyrsoidea*, Rehd. Tree, to 20 ft.: branchlets and petioles pilose: lvs. ovate, usually truncate at the base, sparingly pubescent, often irregularly and remotely toothed, 4–6 in. long: fls. with the lvs., lavender, $1\frac{1}{2}$ in. long, in spike-like racemes forming terminal panicles about 1 ft. long; calyx tomentose, about $\frac{1}{4}$ in. long. Cent. and S. E. China. ALFRED REHDER.

PAVETTA (Malabar name of *P. indica*). *Rubiaceæ*. Tropical shrubs and small trees closely allied to the brilliant ixoras but less showy, not often seen but deserving of attention; flowers white or greenish.

Leaves opposite or ternate, simple, sometimes part-colored, stipules present and joined at base: fls. in mostly terminal bracted corymbs; calyx top-shaped or bell-shaped, the limb mostly with 4 or 5 persistent or deciduous lobes; corolla usually salver-shaped, with a

cylindrical or funnel-shaped commonly slender tube, the throat mostly bearded or pubescent, the limb prevailing 5-parted (rarely 4-parted) into oval or oblong contorted lobes; stamens 4 or sometimes 5, affixed at the mouth of the corolla; style conspicuously exserted, the stigma entire or 2-toothed: fr. a pea-shaped somewhat fleshy 2-pyrenous berry.—One hundred or more species in the tropical and subtropical parts of the Old World, to the Philippines, with recent numerous extensions in Trop. Afr.—Only a few of the species are in cult., and these are known as warmhouse or warm temperate plants.

The pavettas are fine tropical stove evergreens and should be more grown. *P. borbonica* can be propagated from half-ripened wood, leaving an eye and a leaf attached. These cuttings may be put into 2-inch pots, using a mixture of fibry peat and sand in equal parts. These pots may be plunged in a propagating-bed that has a bottom heat of 80° to 85°. Cover with glass so as to keep a humid atmosphere. It will take some little time before they make roots. Keep shaded and moist until this takes place. When roots are seen in the pots, gradually give more air until they are exposed to the full atmosphere of the house. They may also be propagated by being cut down well to make them throw many young soft cuttings that can be rooted with a brisk bottom heat. *P. caffra* will root freely from cuttings of young growth, placed where they have plenty of bottom heat. The pots may be plunged in the propagating-bed up to the rims. Keep shaded, moist and close for about a month. The best season for the increase of this class of plants is January to March.—The general culture for *P. borbonica* is to keep increasing the shifts until they are in 7- or 8-inch pots, using a compost of fibrous loam three parts, fibrous peat two parts, and well-decayed manure one part. Give each pot good drainage. In the spring and summer provide a night temperature of 70°, with 10° to 15° more by day with sun. Supply water when they show dryness of the ball. Keep well syringed. They will need some shade in the summer to keep the foliage perfect. In midwinter the temperature for night may be lowered to about 60°. *P. caffra*, which is a free bloomer, will need different culture. It should be kept growing by shifting as the plants may require, until they are in 6- or 7-inch pots or larger. For summer culture, treat the same as for *P. borbonica* only they will not need so much heat, 60° to 65° being sufficient, with 10° more during the day. They will stand pinching to make them bushy. The temperature in the winter should be from 50° to 55°. The following spring give more pot room and grow on the same as before. Give liquid manure at intervals in the growing season and by autumn they will show bloom. By giving root room, with liquid feeding and by heading in annually, they will bloom for years. Scale and mealy-bug thrive on pavettas, and the plants must be carefully watched. (J. J. M. Farrell.)

A. Foliage variegated.

borbónica, Hort. A foliage plant with unknown fls., referred arbitrarily to this genus: lvs. about 9 in. long, oblong-acuminate, rounded at the base, with a salmon-red midrib, mottled with light green on a dark green ground. Bourbon Isl. Lowe 5.

AA. Foliage not variegated.

B. Calyx-teeth setaceous and much longer than the tube.

caffra, Linn. f. (*Ixora caffra*, Poir. *P. corymbosa*, Houtt.). Shrub with whitish branches, to 6 ft., the branches terete and glabrous: lvs. almost sessile, obovate, glabrous (or in var. *pubescens*, Sond., branches and lvs. pubescent), the margins slightly recurved, to 2 in. long; stipules broad and cuspidate: fls. white, the tube $\frac{1}{2}$ in. long, in densely fld. corymbs; calyx-teeth $\frac{1}{2}$ in. long: fr. black and shining. S. Afr. B.M. 3580. Gn. 60, p. 414. J.F. 3:294.

natalénsis, Sond. Shrub, glabrous, with young branches compressed: lvs. petioled, lance-acuminate, attenuate at base, shining, 3-4 in. long; stipules cuspidate-acuminate: fls. white, in a loose corymb. Natal.

BB. Calyx-teeth short-triangular, shorter than the tube, or sometimes practically wanting.

indica, Linn. A variable small tree or bush, common in India, extending to China and Austral.: glabrous, pubescent or tomentose: lvs. from elliptic to obovate or oblanceolate or even orbicular, at the apex from obtuse to caudate: fls. slender-stalked, white, fragrant, the corolla-tube $\frac{1}{2}$ - $\frac{3}{4}$ in. long: infl. corymb-like, terminal and sessile. B.R. 198, which is var. *polyantha*, Hook. f., with densely crowded pubescent fls. The species has many synonyms. L. H. B.

PÀVIA: *Æsculus*.

PAVÒNIA (J. Pavon, joint author of Ruiz and Pavon's "Flora Peruviana et Chilensis"; died 1844). *Malvaceæ*. Herbs or shrubs, one or two of which are sometimes grown under glass as pot subjects, for the showy bloom.

Tropical plants, tomentose, hispid or glabrescent: lvs. often angled or lobed: fls. of various colors, peduncled or crowded at the tips of the branches: bractlets 5 to many, distinct or more or less connate and resembling a calyx, usually not colored: calyx 5-cut or 5-toothed; petals spreading or convolute-connivent; staminal column truncate below the apex or 5-dentate; ovary 5-loculed, 1-ovuled: ripe carpels surrounding the axis and separating from it, rounded or truncate at top, sometimes winged, indehiscent or imperfectly dehiscent, prickly or awned.—Species about 100, Cent. Amer. to Argentina; also in Trop. Afr. and Asia, to Austral. and the Pacific. The genus is more or less confused with *Goethea*, but that genus, as usually defined, differs in its larger and more showy fl.-bracts and in the smooth carpels. The plants in cult. derive much of their interest from the showy bracts, although *Pavonia* is usually characterized as having bracts less conspicuous than those of *Goethea*.

multiflora, St. Hil. (*P. Wioti*, Morr. *Goethea multiflora*, Nichols.). Robust, with a stout usually simple st.: lvs. alternate, 6-10 in. long, narrowly oblong- or obovate-lanceolate, long-acuminate, serrate or denticulate: fls. in a short terminal corymb; bractlets beneath the fl. numerous, narrow-linear, whorled, red-hairy, curving, in length about equaling the rolled-together purple corolla (which is 1- $\frac{1}{2}$ in. long); calyx-segms. much shorter than the bractlets; column of stamens $2\frac{1}{2}$ in. long and prominently exserted. Brazil. B.M. 6398. F.M. 1877:276.—What is known as *P. intermedia* by gardeners is apparently not *P. intermedia*, St. Hil.; it is said to be derived from *P. multiflora*. There are forms of *P. intermedia*, Hort., known as var. *rosea*, var. *floribunda*, and var. *ermesina*. This group of plants is readily grown from cuttings taken in spring or early summer, and good blooming plants in 5-in. pots may be had by winter. They grow naturally to about one st., and should not be pinched back. They make attractive pot subjects with the terminal clusters of fls. marked by the long-protruding staminal column with hanging bluish anthers, the narrow rolled corolla and the slender conspicuous bracts.

spinifex, Willd. Shrub, to 20 ft., from S. Amer., the st. slender, branches few and virgate: lvs. ovate, cordate, crenate sometimes angled, pubescent on both surfaces: fls. large, yellow, not fragrant, the corolla open; petals obovate; calyx-lobes lanceolate: bracteoles 5 or more, linear, hairy on margin: caps. with 3 spines. B.R. 339.

præmorsa, Cav. Shrub with rodlike branches, from S. Afr.: lvs. broad-ovate or fan-shaped, truncate, obtusely dentate, canescent beneath, with petiole and

setaceous stipules: fls. bright yellow and dark-centered, single on axillary pedicels exceeding the lvs., with 12-14 linear involucre bracts: fr. of downy carpels.—This and *P. spinifex* are reported in Calif.

P. Makoyana, Morr. (*Goethea Makoyana*, Hook.). Lvs. elliptic, short-stalked, with large stipules: fls. in terminal clusters, subtended by large cordate-ovate crimson bractlets. Brazil. B.M. 6427. G.Z. 22:169.—*P. semperflorens*, Garcke (*Goethea semperflorens*, Nees & Mart.). Tall: lvs. elliptic, serrate: fls. usually terminal, purple, with brown bractlets. Brazil.

L. H. B.

PAWPAW: *Carica Papaya* and *Asimina*.

2777. Garden pea, American Wonder. The illustration shows an entire plant, cut off at the surface of the ground. ($\times \frac{1}{2}$)

PEA. As known to horticulturists, the pea is the seeds and plant of *Pisum sativum* and its many forms, one of the Leguminosæ, grown for its edible seeds and sometimes for the edible pods. (Figs. 2777-2783.)

The garden pea is native to Europe, but has been cultivated from before the Christian era for the rich seeds. The field or stock pea differs little from the garden pea except in its violet rather than white flowers and its small gray seeds. There are many varieties and several well-marked races of garden peas. Whilst peas are grown mostly for their seeds, there is a race in which the thick soft green pods, with the inclosed seeds, are eaten. The common or shelling peas may be separated into two classes on the character of the seed itself,—those with smooth seeds and those with wrinkled seeds. The latter are the richer, but they are more likely to decay in wet cold ground, and therefore are not so well adapted to very early planting. Peas may also be classified as climbing, half-dwarf or showing a tendency to climb and doing best when support is provided, and dwarf or those not requiring support. Again, the varieties may be classified as to season,—early, second-early, and late. Vilmorin's classification (*Les Plantes Potagères*) is as follows:

- A. The pea round (smooth).
- B. Plant climbing.
 - c. Seed white.
 - cc. Seed green.
- BB. Plant half-dwarf.
 - c. Seed white.
 - cc. Seed green.
- BBB. Plant dwarf.
 - c. Seed white.
 - cc. Seed green.
- AA. The pea wrinkled (divisions as above).

Left to themselves, the varieties of peas soon lose their characteristics through variation. They are much influenced by soil and other local conditions. Therefore, many of the varieties are only minor strains of some leading type, and are not distinct enough to be recognized by printed descriptions.

Garden or green peas.

Peas are one of the earliest garden vegetables to reach edible maturity. The date at which a mess of green peas could be gathered used to be regarded as an indication of a man's horticultural ability. In modern times, green peas grown far away to the South come to northern markets while the ground is still frozen and are eagerly purchased only to result in disappointment and a longing for the old-time quality. Such disappointment is inevitable, for even with refrigerator cars, express trains, and modern skilful handling, green peas grown hundreds of miles away cannot come to our tables for many hours, often not for days, after they have been gathered, and with an inevitable loss of the freshness, which is essential for satisfactory quality.

Peas do well in cool moist weather and will germinate and make a slow but healthy and vigorous growth in lower temperatures than most garden vegetables. The young plants will even endure some frost with little injury, but the blossoms and young pods will be injured or killed by a frost which did not seem materially to check the growth of the plant. For this reason it is generally most satisfactory to delay planting until there is little probability of a frost after the plants come into bloom.

The cultural requirements are simple, but a thorough preparation of the soil before planting is desirable, and the use of green and fresh manure should be avoided. The best depth of planting varies with the season and character of the soil, and early plantings on clay land should be covered only 1 to 2 inches deep, while later plantings on sandy land do best in drills 6 or 8 inches deep to be gradually filled as the seedlings grow. Generally anything more than surface tillage will do a growing pea crop more harm than good; but any crust formed after rains, particularly while the plants are young, should be promptly broken up.

Of the better garden sorts, from fifty to one hundred good seeds are in an ounce, and a half-pint should plant 50 to 80 feet of row and furnish a sufficiency of pods for a small family for the week or ten days in which they would be in prime condition. For a continued supply one must depend upon repeated plantings.

Most of the best garden varieties can be well grown without trellising, but the sorts growing over 2 feet high will do better if supported. Nothing better for this purpose is known than brush from the woods, but this is not always available and a good substitute is the wire pea trellis offered by most dealers in horticultural supplies, or a home-made one made by strings stretched 2 to 4 inches apart on alternate sides

2778. Garden pea, Champion of England ($\times \frac{1}{4}$)

LXXXV. Good nods of the garden pea, variety Peter Pan.

of supporting stakes. The ingenuity of the home-gardener will devise good forms of trellising.

It is evident that green peas occupy too much ground to be a practical crop for a city lot or small town garden, and generally the town dweller can be most satisfactorily supplied from a nearby market-garden; and the great superiority of freshly gathered local-grown peas over those which have to be shipped in make this one of the best of crops for a gardener with permanent customers. The best cultural methods for field plantings do not differ materially from those given for the garden. No planting is so likely to give a satisfactory yield both as to quantity and quality as on an old clover sod on a well-drained clay loam, which should be well plowed in the fall or early winter and the surface worked into a good tilth as early as practicable in the spring.

Planting can be best done with a seed-drill so arranged that the rows are 12 to 36 inches apart, according to the variety, with occasional rows left blank for convenience in gathering.

2779. Garden pea, Nott Excelsior. ($\times \frac{1}{2}$)

Picking should be done after sundown or in early morning before nine o'clock and care be taken not to bulk the pods, as they are liable to heat and spoil.

Peas for canning.

There is no modern industry in which there has been greater improvement within the past ten or more years, both as to methods and the quality of the product, than in the canning of vegetables. This is especially noticeable in canned peas. First there has been a great betterment as to the varietal quality of the stock used. For canning, particularly when modern methods of harvesting and processing are used, it is important not only that the green peas be sweet and palatable, but that the largest possible proportion of the pods shall be in prime edible condition at the same time, and canners are influenced by these qualities in selecting varieties for their plantings, and in the cultural methods followed. The development of each planting is closely watched by an expert, who directs that it be cut and delivered at the factory on the day when he judges it will be in the best condition, the time for individual crops being sometimes modified by the capacity of the farmer to deliver and the factory to handle it. Not infrequently certain crops are left to ripen and be harvested as grain because of such conditions. In hot and

sunny weather, the vines are cut either after five in the afternoon or before nine in the morning, hauled to the factory and from the wagon go direct to a specially constructed threshing-machine or "viner," which separates the peas and delivers them on a moving inclined belt, which throws out any bits of vines or pods. They are then washed and graded, and go to the processor. So promptly is this work done that it is known of peas being in the cans and being cooked before the wagon on which they were brought from the field could start for home. Usually peas put up by a well-managed cannery come to the table in more palatable condition than so-called fresh peas which were gathered ten to twenty-four hours before and shipped from 10 to several hundred miles to market.

Canners who are particular as to the labeling of their output often separate it into different grades, determined by the variety and size of peas and labeled somewhat as follows:

Varieties	1st	2nd	3rd	4th
Small, smooth seed, not over.....	16/64	18/64	20/64	Run of crop
Small, wrinkled seed, not over.....	18/64	20/64	22/64	Run of crop
Large, smooth seed, not over.....	20/64	22/64	24/64	Run of crop
Large wrinkled seed, not over.....	20/64	24/64	26/64	Run of crop

Varieties and seed.

Few vegetables have developed greater varietal differences affecting their horticultural or culinary value than garden peas. As to vines, there are sorts from 6 inches to 6 feet in height and those which very rarely form more than a single stem, while others are so branched that they often are wider than tall; some mature their crop very early and all at once, others not until the vines are fully grown or continuing through a long season; pods which are so broad and long that the inclosed peas never fill them, others in which the growing peas very often split the pod open; peas which are green, yellow or white, smooth and hard; others which are wrinkled, distorted and comparatively soft, even when fully mature. Very conspicuous variations of little practical importance are sometimes correlated with invisible qualities which are of great importance.

When grown for seed, peas of the garden varieties yield a comparatively small fold of increase, seldom over 10 or 12 and often only 2 or 3, so that it is more difficult than with most vegetables always to secure full supplies of certain sorts, and seedsmen's stocks are constantly changing, not only as to character but name. The following are now very popular varieties: Extra-early smooth-seeded—Alaska or Prolific Extra Early; early wrinkled seeded—Thomas Laxton, Gradus, Surprise; dwarf Excelsior, either the Notts or the Suttons; midseason—Advancer, Admiral, Senator; late—Champion of England, Strategem. However, one should confer with the seedsmen

2780. Pea, Nott Excelsior. ($\times \frac{1}{2}$)

2781. Pea, Pride of the Market. ($\times \frac{1}{2}$)

as to the most available stock best suited for the particular needs.

Sugar or edible-podded peas.

These are a class little known in this country, but are largely grown in Europe. They are characterized by large more or less fleshy and often distorted pods, which are cooked when in the same stage of maturity and in the same way as string beans. Varieties have been developed in which the pods are as white, tender, and wax-like as those of the best varieties of wax-podded beans.

Field peas.

There are a number of kinds of field peas in which the vines are very vigorous, hardy, and productive and the peas generally small, hard, and becoming tough, dry, and unpalatable as they ripen. In one variety of this class known as French Canner, the very young and small peas are sweet and tender, and in this stage are put up by French canners under the name of "petit pois." The larger-seeded Marrowfat peas were formerly commonly used by canners, and large quantities are still packed. If this is done while the peas are sufficiently young and tender they make a fairly good product.

2782. Pea, Stratagem.
($\times \frac{1}{2}$)

2783. Pea, Melting Sugar.
($\times \frac{1}{2}$)

Split peas.

Large quantities of field peas, mostly of the smaller-seeded kinds, are used for split peas, the preparation of which consists in cleaning and grading, kiln-drying, splitting, and screening out the hulls and chips from the full half peas. This is all done by special machines, mostly of American invention. The annual consumption of split peas in the United States is about 50,000 barrels, of which, before the European war, 75 per cent came from abroad.

W. W. TRACY.

PEA. Congo P., *Cajanus indicus*. Everlasting P., *Lathyrus latifolius*. Glory P., *Ctianthus Dampieri*. Hoary P., Pigeon P., *Cajanus indicus*. Scurfy P., *Psoralea*. Sweet P., *Lathyrus odoratus*.

PEACH. The tree and fruit of *Prunus Persica* (or *Persica vulgaris*), widely cultivated in the United States and parts of Canada for home use and market.

In the northern prairie states and on the plains, and in the colder parts of the mountain regions of the West, the peach is little grown or is even altogether absent; yet the range of adaptability is constantly extending as the local conditions and requirements become better known. There is less dependence on

"fruit-belts" than formerly, in which some special favor of climate or location was supposed to exist. Some parts of New England are well adapted to commercial peach-culture. Parts of Canada bordering the Great Lakes, and regions in Nova Scotia, are prominent peach districts. Varieties of special adaptability to climate and useful also for particular purposes have arisen in recent years; and the requirements of the peach are now better understood than formerly. The range of its cultivation will probably be considerably broadened in years to come.

The discussion of the peach is here comprised in four articles:

	Page
The culture of the peach (M. A. Blake).....	2492
Peach-culture in the South (J. H. Hale).....	2500
Peach-growing in California (George C. Roeding). .	2503
Protecting peach trees in cold climates (W. Pad-dock).....	2504

The culture of the peach.

The marked feature in the development of the peach industry in the United States since about 1900 has been the extension of the areas of commercial peach-production because of the introduction of hardier varieties such as Carman, the discovery of materials and methods that make certain the control of peach-scab and brown-rot, and the organization of fast-freight and refrigerator-car service that permits of successful long-distance shipment of this perishable fruit.

The introduction of the San José scale was the cause of the destruction of hundreds of thousands of peach trees throughout the country from about 1900 to 1907, the period of greatest damage varying to some extent in each district. The growers who persisted in the business were those who had the capital, energy, and persistence to take up the new problem of spraying, and these men may appropriately be termed the pioneers of the modern peach business.

The necessity of spraying to control the scale also focused the attention of the growers upon all other factors of peach-production except marketing, which for the time presented few difficulties because of the great reduction in the number of bearing trees and the ability of the local markets to absorb much of the crop produced.

Peach-scab and brown-rot caused serious damage to the crop annually in central and southern peach districts until the self-boiled lime-sulfur summer spray was proved to be a successful remedy.

The development of large commercial areas at long distances from market has resulted in better grading and packing. The Georgia six-basket carrier has become the popular shipping package from southern New Jersey to Georgia, Alabama, and Texas. (Fig. 2707.)

Innumerable changes and improvements in the growing and handling of the crop have occurred within the last ten years.

The United States Census reports show many interesting facts in connection with the extent and development of the peach industry. A few trees are found in every state in the Union. According to the Census of 1910 only three states, Wyoming, North Dakota, and Montana, have less than 5,000 trees. Five other states, Minnesota, South Dakota, Wisconsin, Maine, and Vermont, have less than 10,000 trees. The most significant fact, however, is that twenty-six states reported a total of more than 1,000,000 bearing trees each, which definitely shows the extended area over which this crop is produced to some commercial degree. The Census for 1910 shows Georgia to lead in the total number of bearing trees with 10,609,119; Texas is second with 9,737,827; and California is third with 7,829,011 trees. On the basis of total number of trees, however, Texas leads with 12,696,640; California is second with 12,238,573, and Georgia is third with 12,140,486.

The Census reports also indicate the general trend of the industry in no uncertain way. In 1890, five states led prominently in the total number of bearing trees, as follows: Maryland, 6,113,287; Kansas, 4,876,311; Delaware, 4,521,623; Texas, 4,486,901; and New Jersey, 4,413,568. The greatest peach district in the

2784. Peen-to peach.—*Prunus platycarpa*. ($\times \frac{1}{2}$)

country at that time was comprised by the states of Maryland, Delaware, and New Jersey, with a total of more than 15,000,000 trees.

The three leading states in 1900 were, Michigan with 8,104,415 trees, Georgia with 7,668,639 trees, and California with 7,472,393 trees. The states of Maryland, Delaware, and New Jersey, which geographically comprise one district, reported a total of a little more than 9,000,000 trees, the San José scale and other factors having reduced the total about 6,000,000 trees. Yet as a peach district, this still held its place as having the greatest total number of trees.

The Census of 1910, however, shows that this number was greatly reduced during the period from 1899 to 1909, having less than 4,000,000 bearing trees. This great reduction and loss was due largely to the introduction of the scale. Michigan reports a loss during this period of more than 5,000,000 trees, and Ohio more than 3,000,000. The following states made gains during this period: New Hampshire, Vermont, Illinois, Idaho, Missouri, Nebraska, South Carolina, Georgia, Tennessee, Alabama, Arkansas, Louisiana, Texas, Colorado, New Mexico, Utah, Washington, and California. Summarized to a few words, the Census indicates that while the Middle Atlantic and Great Lakes districts were suffering severe destruction of trees, the southern and western districts were developing. These facts lead one to wonder as to how much of a part the San José scale played in the development of these latter districts, and whether such development could have maintained itself in some cases without the good markets and high prices occasioned by the widespread destruction of trees in the East.

The Census of 1910 is of particular value in showing the recent trend of the industry, because the number of trees in bearing and those not in bearing were tabulated separately.

The western states, Idaho, Oregon, Utah, and Washington are increasing their plantings. The young trees not in bearing in Massachusetts, Michigan, and New Jersey were greatly in excess of those producing fruit in 1909. West Virginia has also been planting peaches extensively in recent years.

The extensive planting of peaches in the eastern and Middle Atlantic states, following the earlier destruction by yellows, was only just beginning in 1909, when the last Census was taken. Since that time, millions of trees have been planted and have come into bearing. As a result, the marketing factor became the most important peach problem in 1915. Southern districts can no longer expect the prices of former years in the great eastern markets, the Middle West is growing quantities of peaches and so also are the states along the Great Lakes. The problem at the

beginning of 1916 is where and how can the crops from these trees be marketed profitably.

In any broad discussion of the peach regions of North America, the Ontario district of Canada should not be overlooked. Situated south of the western end of Lake Ontario, climatic conditions are so modified that such yellow-fleshed varieties of peaches as St. John, Fitzgerald, Elberta, and Niagara can be grown successfully in large quantities.

The northern limits of peach-production extend from the southeastern shore of Lake Ontario along the southern shore of Lake Erie and the eastern shore of Lake Michigan as far north as the Grand Traverse on the 44th parallel. This area is often termed the "Great Lakes Belt." Beginning in southwestern and central Massachusetts, another commercial peach area extends across Connecticut, Long Island, the Hudson River Valley, New Jersey, eastern Pennsylvania, Delaware, and Maryland. The Coastal Plain areas in New Jersey, Delaware, and along the eastern shore of Maryland are favorable to peach-production, and the fruit is grown to within a few miles of the seaboard. Farther south, the Coastal Plains area is unfavorable to successful commercial production and the industry is transferred to the Piedmont area across Virginia, North Carolina, and southward to the Gulf districts in Alabama and Texas. Florida has too warm a climate to suit the common standard varieties of peach and has developed a special type from the South China race.

The central or Mississippi Valley district extends from Texas across Oklahoma and Arkansas, Missouri and Kansas to Iowa, Illinois and Indiana, practically connecting with the Great Lakes area. The Pacific Coast Belt includes California, and areas in Nevada, Utah, Colorado, Oregon, and Washington. There are many areas in these so-called "peach-belts" that are not favorable to peach-production, but they indicate the general grouping of the industry.

Varieties and types.

All of the common forms of the peach belong to the species *Prunus Persica*, but are sometimes grouped under the name *Amygdalus Persica*. The flat or Peen-to peach is *P. platycarpa*. The United States Department of Agriculture, through its Bureau of Foreign Plant and Seed Introduction, has secured a form of peach from China known as *A. Davidiana* which is used there as a stock for certain cherries. It is said to be very hardy and may prove of value in breeding work, or as a stock for the peach. Its fruit is not attractive enough for use as it is now developed. Several other forms

2785. Honey peach. ($\times \frac{1}{2}$)

2786. Cabler peach. ($\times \frac{1}{2}$)

or types have been collected in China by Frank N. Meyer, of the Department of Agriculture, and sent to the United States for propagation and study. See the article *Prunus*.

The common types of peaches have been grouped into certain races. Onderdonk (Rept. Commr. Agric.,

2787. Crawford peach. ($\times \frac{1}{2}$)

1887) and also Price have placed North American peaches in five groups: (1) The Peen-to or flat peach race, comprising the variety known as Peen-to (Fig. 2784), and also the Angel, and Waldo; (2) the South China race, with oval long-pointed fruit with deep suture near the base, represented by the Honey (Fig. 2785); (3) the Spanish or Indian race, with very late yellow firm often streaked fruit, represented by various southern varieties, as the Cabler (Fig. 2786), Columbia, Galveston, Lulu, Texas, and Victoria; (4) the North China race, with large mostly cling or semi-cling fruit and very large flat leaves, represented by the Greensboro, Waddell, and Carman; (5) the Persian race, including the common varieties of the mid-country and the North, as Crawford (Fig. 2787), Mountain Rose, and the like. The so-called North China and Persian types of peaches are now very much mixed in commercial varieties.

We have been content to say that Elberta (Fig. 2788) is of the North China type, when it is plainly mixed with the Persian, and when studied carefully its characters resemble the Persian type even more than they do the North China. Two types of peach blossoms are commonly recognized (as shown in Fig. 2790), yet there are three distinct types, the large bloom, typical of Greensboro and Waddell and the North China type, the medium bloom of such varieties as Elberta and Belle, and the small bloom of Early and Late Crawford, and others. The botanical significance of these types is not well understood.

A double-flowered peach (Fig. 2789) is sometimes cultivated as an ornamental, as well as a purple-leaved form. A form of the cultivated peach growing wild near Peking, large-flowered, is shown in Fig. 2791.

Propagation.

The peach is universally propagated by means of the pits or seeds. A few are sometimes secured by budding upon plum or even cherry stocks, but this dwarfs the tree and makes it susceptible to various stock troubles.

So-called natural seedling pits or seeds gathered in Tennessee and North Carolina are said to be the best for propagation work. Such seeds are considered to be more viable and to produce hardier stock than pits from cultivated varieties. Considerable quantities of so-called "seedling" seeds have undoubtedly been secured from canning factories and represent commercial varieties, although one can readily detect the difference between them. It has not been definitely shown that wild seedling pits will produce a stock that is any more hardy than that which might be secured from the pits of some of our hardier cultivated varie-

ties. Seeds or pits for propagation are treated in two ways. Where severe freezing weather occurs they are commonly planted in the autumn in nursery rows from 4 to 6 feet apart. The pits are scattered a few inches apart in the rows and covered to a depth of about 2 inches. In less severe climates, the pits are stratified very shallow in autumn, are dug up in the spring and the kernels separated from the soil and shells, and planted in nursery rows. By this method, any pit or seed which is not cracked open by the action of the frost may be broken by the use of a hammer. Pits not affected by the frost usually fail to grow the first season, but may do so the second year.

The pits should be planted in good soil and be given careful cultivation so that the seedlings will be at least 24 to 30 inches high by the latter part of August of the first season, and in condition for budding. The buds are inserted the latter part of August or early in September, and simply become united with the seedling stock without making any growth. Early the following spring the seedlings are cut back just above the inserted buds, and all shoots developing from buds of the stock itself are kept rubbed off. In this way the desired bud develops into a vigorous well-branched shoot or tree which should be from 3 to 6 feet high at the close of the season's growth, and is ready for sale that fall or the following spring. So-called "June buds" are secured by budding vigorous seedlings in June and selling the resulting trees in the fall or the spring following. Such trees are smaller and are seldom equal to one-year-old trees except possibly for planting in the South. In Fig. 2792, at the left, is a well-branched one-year-old nursery tree; at the right a slender tree of the same age and height, and in the center a June bud.

The question as to whether trees should be propagated north of the region in which they are grown is a common one. Evidence has shown that it makes little difference as to the latitude in which the trees are raised if they are well grown and are free from injurious

2788. Elberta peach. ($\times$ nearly $\frac{1}{2}$)

insects and diseases. It is generally best, however, to purchase trees as near at hand as good ones may be secured.

The ideal climate for the peach is one in which the winter extremes do not go much lower than zero at any time, and no warm periods of many days' duration occur in winter. The absence of late spring frosts and presence of bright sun during the ripening period are also important essentials. Extremes of either warmth or cold in winter are almost equally detrimental.

Soil.

The peach will succeed upon a wide range of soil-types, but prefers a sandy loam. It will also develop exceptionally well upon gravelly or stony loams, if deep and well drained. Heavy poorly drained soils should be avoided. It also thrives on sands.

Site and elevation.

The type of peach-growing business one expects to engage in has much to do with the kind of location and site that should be chosen.

A successful local market business may be established even upon disconnected areas and at some disadvantage. But extensive peach plantings for supplying the wholesale markets should be planted upon uniformly favorable areas near good shipping-points and where plenty of labor is available. Locations should be sought where peaches can be grown and placed on the market cheaply because of large annual yields and low cost of production and marketing.

The elevation above sea-level at which peaches are planted in any region is a most important matter. It is not sufficient that the orchard be on land that is higher than its immediate surroundings. In some localities an elevation of 150 to 200 feet is sufficient to secure good yields, while in others one must seek altitudes of 800 to 900 feet, or even more, for successful crops. The site of the orchard should also be readily accessible, so that fertilizers, spray materials, and packages can be delivered cheaply and so that the crop may be picked, packed, and shipped economically. Uneven land broken up by gullies or wet areas is to be avoided, as well as hilly areas that are difficult to reach by team and expensive to manage.

The particular exposure is not important in a relatively flat country. In hilly or mountainous sections, it may become so. Severely exposed situations should be avoided, as well as warm pocketed areas. Some protection from severe prevailing winds is most desirable and does not increase the danger of too early blooming if good air-drainage prevails.

Establishing the orchard.

A well-defined plan should be drawn up before planting is begun. The peach is a relatively short-lived tree, and packing-houses and permanent buildings should be located in connection with roadways and plantings so as to result in the most economical procedure of the work.

2789. Bloom of double-flowered peach. ($\times \frac{1}{2}$)

2790. Bloom of large-flowered and small-flowered peaches. ($\times \frac{1}{2}$)

The selection of varieties must be made previous to the planting of the orchard. Specific recommendations for each district cannot be given in a brief article, but some general statements as to the variety question follow. Yellow-fleshed peaches are preferred by most

See Garden and Forest, 5: 438.

markets. Such varieties as Mountain Rose, Reeves, Stump, Oldmixon, and the Crawfords are falling behind in popularity except in a few localities. Better varieties are needed commercially. Carman and Belle (of Georgia) are rapidly gaining in commercial importance. New varieties, such as the J. H. Hale, are demanding recognition. Elberta is still the most popular single variety. It is the most widely successful commercial variety of any of our tree-fruits. In making a choice of commercial varieties for any section, a few hardy sorts that are known to do well in the locality are the safest to plant. One should also have enough trees of each variety for economical growing and marketing.

Vigorous one-year-old trees that will caliper $\frac{5}{8}$ to $\frac{3}{4}$ inch and are from 3 to 5 feet in height, as illustrated at the left in Fig. 2792, are an ideal size to plant. They should be free from yellows or little-peach or rosette, root-gall, scale, peach-borers, or other injurious peach enemies.

Fall planting is successful with well-ripened trees in localities in which the winter weather is not severe and where soils are sandy and well drained. In northern districts, fall planting is less likely to be successful. In spring planting, the land should be prepared and the trees set as early as soil conditions permit.

The trees should be set about 20 feet apart each way under average conditions. In some localities 18 feet is sufficient distance, while in others 25 feet is not too much.

Vegetable crops, such as peas, beans, tomatoes, and potatoes, may be grown between the rows of young peach trees for the first and second seasons, after which the practice is of doubtful economy.

Tillage.

The apple is sometimes grown successfully under the sod-mulch system, but attempts to manage the peach in the same way have commonly resulted in failure. The soil of the orchard should be plowed or disced into

a fine mellow condition in the spring as soon as it becomes dry enough to "work" well. This state of tillage should then be maintained until about mid-season by frequent harrowing. The time when culture should cease varies with the locality and the variety.

2792. Different forms of peach trees for planting.

It is seldom possible to cultivate later than ten days or two weeks previous to the ripening of the fruit, as the branches become bent down with the crop. Early varieties should commonly receive one or more cultivations after the crop has been picked. In the South, tillage is often stopped in bearing orchards in late June, while in the North it is continued until late July. In dry seasons, late varieties require additional culture to reach good size. A large proportion of vegetable matter in the soil is an important factor in the production of large fruit, especially in dry seasons. Cover-crops should be grown wherever possible.

Fertilizing.

Rate and character of growth is a great limiting factor in peach-production. A certain amount of growth is necessary to maintain vigor and a proper number of flower-buds. The extent and time of greatest growth determines size, color and quality of fruit to a marked degree. The application of plant-food or fertilizers is a feature of orchard practice that directly concerns rate of growth.

Trees in full bearing should make an annual growth of at least 12 to 18 inches at the tips of leading branches in most peach regions to maintain a maximum production. Fruit-growers should apply fertilizers to secure a growth according to their soil type and its conditions. If such a growth is obtainable without fertilizer, its application may prove detrimental, while if the soil is thin and poor, heavy fertilizing will be required for good results.

Under the average conditions, the equivalent of 100 pounds nitrate of soda, 150 pounds muriate of potash, and 400 pounds acid phosphate will not be found to be excessive, and additional nitrate will be needed in many cases. In districts where the winters are severe, however, nitrogenous fertilizers must be applied sparingly.

Pruning.

Two distinct types of pruning are practised with the peach. One is to allow the tree to form its own particu-

lar habit of development except to thin out the branches somewhat as illustrated in Fig. 2794 as contrasted with Fig. 2793. Figs. 2795 and 2796 show other examples of this treatment. The other is to practise annual cutting back of the branches as well as thinning out, to produce a strong compact and yet well-spread tree, as illustrated in Fig. 2797. The first method may result in the somewhat earlier production of fruit, as much pruning tends to delay fruiting. Trees whose main branches are not cut back annually are more likely to suffer from breakage not only in seasons of heavy crops, but also during ice-storms in winter. On each tree, also, the vigorous fruit-bearing parts tend to extend farther away from the main trunk each year. Fig. 2793 illustrates the habit of growth assumed by an unpruned tree.

The peach produces its fruit-buds upon the one-year-old wood-growth. On vigorous twigs the buds commonly occur in groups of three, as illustrated in Figs. 2798, 2799, the two outer buds being flower-buds and the center bud a leaf-bud. Sometimes all three buds are flower-buds and sometimes only one. Single flower-buds may frequently occur also.

Many fads in pruning prevail, which have no economic bearing upon the amount and quality of the crop. The height to which the trees should be cut back when planted varies with different growers, but from 18 to 24 inches is a good average. Some prefer the extreme of 6 inches, but such low trees often make borer-removal difficult.

At the end of the first season's growth, the real pruning of the tree begins. At that time the main branches of the tree should be chosen. The best three or four well-placed branches should be chosen to form the framework for the future top of the tree as illustrated in Figs. 2800, 2801. These should be distributed upon the trunk and not issue from the same point, although on different sides, as in Fig. 2802. In some cases a tree may have developed only a single irregular shoot and this will then require severe cutting back to encourage branching at the desired height. Fig. 2803 shows a good two-year-old tree, low-headed.

When several side branches occupy much the same space or cross one another, a choice of one should be made and the remainder pruned off. The amount of cutting-back to be practised at the close of the first season upon the main branches selected for the permanent framework of the tree depends on the form of the tree. If it is compact, vigorous, and of the desired form, the cutting back of each tip to the first good side branch is all that is necessary. Should one main branch be irregular in growth, more severe pruning is desirable. Severe cutting-back, save in the case of poorly formed trees, only delays fruiting and increases the expense.

During the second summer, the necessity for severe winter pruning may be prevented by the rubbing off of any shoots that tend to develop as suckers low down upon the trunk, or in the center of the tree where they are not wanted,

2793. Unpruned thick-topped peach tree.

and the pinching back of the tips of any branches that tend to develop in an irregular manner. The removal of shoots should be done before they are more than an inch or two in length. The pinching back of irregular shoots should be accomplished in June or early July before they are more than 18 or 20 inches in length. The removal of much growth and foliage in the summer may cause a severe check to the tree.

The annual dormant-season pruning beginning with the second year should be somewhat as follows: The main branches will develop numerous side branches and the strongest and best placed of these should be retained. A well-formed tree is not only agreeable to look upon, but furthermore the maximum production of good fruit is secured only when the greatest possible amount of vigorous fruit-bearing surface is properly exposed to light. The annual cutting back of the leading branches to the first good side branch will result in well-spread vigorous trees. The cutting of a branch to an "outside bud," however, does not change the direction of growth of that branch to anywhere near the same degree. The cutting back of the branches causes a thickening of the top, and some thinning out of shoots and branches is necessary, otherwise the fruit will lack color.

A central leader is avoided in the pruning of peach trees, and any shoots which tend to shut out the light from the center of the tree should be kept pruned back and not allowed to become more than fruiting twigs. The general form of the tree should be about complete at the close of the third or fourth summer after planting, and the annual pruning will largely consist of the removal of any broken branches and the cutting back of the annual growth on each branch about one-third or one-half, according to the variety and the amount or length of growth. Pruning is often the most economical method of thinning, and this point should not be overlooked.

After peach trees have fruited for several years, they commonly require a severe cutting back to reduce the size of the top and to secure more vigorous wood. Such a cutting back should be practised whenever the fruit-buds are destroyed in winter. All branches may be cut back into wood-growth formed the two or three previous seasons. It is never advisable to saw the main branches back to mere stubs a foot or more in length except upon young trees that are to be top-worked.

Thinning the fruit.

Thinning is now a regular feature of good orchard-management. Small fruit sells for low prices at all times and in seasons of heavy crop-production can hardly be disposed of at any price. When trees are allowed to mature as much fruit as will set in a favorable season, much breakage of branches is the usual result. The small green fruits should be thinned as soon as the so-called "drop" or the natural thinning occurs. Sometimes this fails to take place and then the fruit should be thinned as soon as it is about the size of a shelled hickory-nut. Thinning the

fruits to not less than 6 inches apart will not reduce the yield of the tree, and 8 inches apart is not too much to secure extra-large fruit, especially upon such sorts as Waddell, Crosby, Mountain Rose, and Stump, which tend to be small to medium in size under average conditions.

Harvesting the fruit.

This part of the peach business really begins as soon as a crop is definitely assured for the season. The

2795. Peach trees allowed to take their natural form.

necessary number of packages should be purchased, the packing-house put in order, and arrangements made for the needed number of teams, trucks, pickers, packers, and other labor.

When the fruit is ready to pick, the work should be organized with one man in constant charge in the orchard. He should direct the pickers and see that each one picks all the fruit that is mature enough at any one time and yet does not take off that which is too green. An efficient picking-crew is necessary in order to secure good results at the packing-house.

White-fleshed peaches change from a light green to a cream-white ground- or under-color as they mature. So-called yellow-fleshed varieties change from a yellowish green to various shades of yellow or orange as they ripen. Pickers should be instructed to determine the maturity of a fruit by its color, and be corrected if they attempt to test it by pressure with the fingers. Good pickers will harvest from sixty to one hundred sixteen-quart baskets a day from well-pruned trees.

The fruit is not uncommonly picked directly into the package in which it is sold, but this practice is rapidly passing in favor of a distinct picking-basket. The most common type in use is a round flat-bottomed wooden stave basket of sixteen quarts capacity.

A low-wheeled wagon is best adapted for hauling the fruit from the orchard to the packing-house.

Packing the fruit for market.

Some sort of a packing-house is necessary when any considerable amount of fruit is handled. A shelter against rain is imperative to prevent the warping of wooden packages. Rapid work in packing can best be organized in a building with a wooden or cement floor and where stencils and tools can be kept in order. A long and relatively narrow packing-house with large doors upon either side is likely to prove the most economical for the handling of the fruit.

Packages, tables, and box- or crate-presses should be arranged in a way to promote rapid and efficient work. No distinct grades of peaches, unfortunately, have become recognized in any broad way. Persons employed as packers should be chosen for their honesty and interest in the business as well as for their rapidity in filling the packages.

2794. The interior weak branches are removed. (Compare Fig. 2793.)

The common commercial packages now in use are the sixteen-quart Jersey or Delaware basket and its modifications, the Georgia six-basket carrier, the Michigan bushel and half-bushel, the Climax basket (Fig. 2804) and the western or California box.

2796. The vase-form, or so-called natural-headed tree, in old age.

Packages often arrive on the market in bad condition because they have not been sufficiently well-filled at the orchard. The fruit must be packed tightly enough so that it cannot move in the package during transit.

Simple mechanical graders have been used for some time in some of the peach regions, but have never been entirely satisfactory. The new types of graders are still in the experimental stage. See *Packages*, page 2426, for description of types of fruit-graders.

Markets.

All the large cities in the United States and Canada, in addition to the local towns, consume large quantities of peaches. A grower who is situated near a large local market can allow his fruit to become well-ripened and haul it by wagon or truck without requiring other transportation facilities. Much of the crop must go to market by rail, however, and if in transit more than a few hours, some refrigeration is necessary. Refrigerator cars are employed for this. The large so-called "Fruit-Growers Express" or "Dispatch Cars" will hold five and one-half tons of ice and are capable of carrying 448 Georgia carriers in four tiers, or 558 crates in five tiers.

All crates, boxes, or baskets should be so arranged when placed in refrigerator cars as to allow of a free circulation of air.

Precooling of peaches previous to shipment is practised to some extent, but is not yet common. One who engages in peach-production upon a large scale cannot depend upon local markets to take his entire crop at a profit and must be prepared to ship to the wholesale markets. The ideal shipment is the carload. To ship at least a carload of fruit constantly, one needs to have from about 1,000 to 1,200 trees of each variety in full bearing.

Insects.

The most serious insect enemies of the peach are the borer, San José scale, and curculio. A few years

2797. Headed-in peach tree.

ago the scale was considered the most troublesome of the three, but the borer is now the most difficult to control. The mature insect is wasp-like in appearance, the male shining steel-blue in color with an orange-

yellow band about the abdomen, while the female is of a deeper and duller color. The eggs are laid on the trunk near the ground from June to as late as September, or possibly October. The "grubs" hatch and work their way under the bark and there feed upon the inner bark for about twelve months, when a case is formed of the "sawdust" and other materials, in which the pupa stage is passed. One or two borer larvae may completely girdle a nursery tree, while several may accomplish similar damage on a young tree in the orchard. In any case the infested tree is greatly weakened. The presence of borers is easily detected by the mass of gum and "chewings" at the base of the tree.

A great variety of materials has been tested as coatings to prevent the entrance of borers, but none has proved to be entirely successful. The expansion of the bark because of growth causes numerous cracks in the coating of most materials that are applied and the borers gain entrance. A soft grade of asphaltum applied to the trunk for a few inches above and below ground is a promising material now under test. Lime-sulfur, white-wash, and other materials may have some value as repellants, but are not very efficient.

The common practice is to remove the soil to a depth of 6 to 8 inches about the trunks of the trees in early spring and to kill the borers by means of a knife and a short piece of wire. Some growers examine their trees in autumn, but there is danger of winter injury unless the soil is put back before severe winter weather occurs.

The San José scale is now easily controlled by a thorough dormant-season spraying of lime-sulfur diluted to a specific gravity of 1.03 to 1.04.

The plum-curculio is a small snout beetle about $\frac{1}{4}$ inch in length with four irregular humps upon the wing-covers. It is dark mottled gray in color with black markings. The principal damage caused by this insect is during seasons of light crops or upon trees just coming into bearing when the loss of a proportion of the green fruits reduces the crop. In seasons of heavy crops, the loss of a proportion of the green fruit may not prove to be of economic importance. The beetle appears in the orchard about blooming time and feeds on the foliage until the calyces are shed from the fruits, when egg-laying begins. If the egg hatches, the larva makes its way to the center of the peach and feeds upon the developing germ, causing the fruit to fall from the tree later. The mature beetle may also do considerable feeding upon the outside of the peach while it is still small, causing irregular blemishes that may markedly effect the commercial value of the fruit. The curculio is most troublesome when the orchard is surrounded by grasslands and hedgerows of weeds and native trees. When much of the area is under cultivation and good orchard practice prevails, the damage is greatly reduced. A spraying of arsenate of lead just after the petals fall, and again just as the calyces are shedding from the fruits, will destroy many of the curculio. It is best to combine the lead with the self-boiled lime-sulfur to secure a better distribution of the lead and prevent any burning of foliage by an inferior product.

The bark-beetle is a small black insect not more than $\frac{1}{8}$ inch in length that attacks the bark upon weakened trees, causing gum to exude in spots upon the trunk and branches. Fortunately, the insect usually causes little or no damage to vigorous healthy trees and its presence indicates that some other factor is really to blame, although it is sometimes reported on healthy trees. The black peach aphid is occasionally troublesome upon light soils, but good culture and a vigorous

2798. Fruit-buds of the peach with leaf-bud between.

growth commonly prevents any serious check to the trees.

Various beetles and grasshoppers may cause some damage at times by feeding upon the peach, such injuries being most common in orchards in which grass or weeds are allowed to grow freely.

Diseases.

The peach is subject to the attacks of a considerable number of diseases. The most difficult to combat are yellows, little-peach, and rosette. The causes of these diseases are still unknown. Some suggest the presence of a fungus, others an organism too small to be detected by the ordinary microscope, and there is also the possibility of enzymes.

The advanced stages of yellows are indicated by a premature of the fruit from a few days to at least two weeks in advance of the normal season. Such fruit is commonly red-spotted and blotched in its coloring and may be insipid or bitter in flavor. Affected trees may also develop sickly wiry twig-growths on the trunks and branches.

Little-peach is indicated by a characteristic drooping of the foliage and by the fact that the fruit is smaller and matures later than the fruit on healthy trees.

Rosette occurs only in southern districts and is readily distinguished by the tufts of leaf-development. This disease is fatal within twelve months in many instances.

It is not known whether these diseases are entirely distinct or not, but they have been so regarded. Yellows and little-peach attack all varieties in about the same proportion. Infection does not appear to take place through the soil, flowers, or seed. These diseases can readily be transmitted to healthy trees or stocks, however, by budding. Buds taken from the apparently healthy parts of diseased trees have invariably reproduced the diseases.

The recognition of early stages of yellows and little-peach have shown that these diseases are too frequently distributed in nursery stock. It is now known that a tree may be infected with either of these diseases for three or four years without showing any prominent symptoms. When good growing conditions are provided, the true state of affairs may be masked for a time, but a check to growth will result in the prompt appearance of the advanced stages of disease.

Many cases of so-called "cures" of yellows have been announced, but all have been without sound basis. Too often trees affected with borers, winter injury and other troubles are considered to be affected with yellows. Diseased trees should be destroyed as soon as detected. When such trees are left in an orchard, the disease spreads to surrounding trees until all are affected. If all diseased trees were destroyed annually in any district and no diseased nursery trees were introduced, the annual loss could readily be kept as low as 1 per cent, without much doubt. Yellows attacks Japanese plums as well as peaches, and this should not be overlooked in control work.

Peach leaf-curl, brown-rot, peach-scab and mildew are fungous diseases of the peach which cause much damage annually. The leaf-curl attacks the foliage in early spring just as the leaf-buds open, and the leaves become curled, thickened, and distorted. The tips of shoots may also become affected and the disease is occasionally seen upon the fruit in a fan-shaped discolored area. The affected leaves finally turn brown, and fall from the trees in early summer. In severe attacks, the trees are almost completely defoliated, greatly reducing their vigor and causing them to lose most of the fruit which may have set. This disease is readily controlled by a spraying with lime-sulfur, as directed for the scale, before the leaf-buds begin to make growth. After the leaf-buds begin to expand, however, the spraying may not prove effective. Recent experiments have been tried with apparent success in

New York of fall spraying for leaf-curl, as late as the first part of December.

Brown-rot was formerly one of the dreads of the peach-grower. Thousands of baskets of fruit frequently rotted on the trees just at harvest time. Not until the value and safety of self-boiled lime-sulfur summer spray was demonstrated by Scott were the peach-growers supplied with an effective remedy for the disease. This affliction may not only cause a rapid decay of the fruit at ripening time, but it sometimes attacks the blossoms and causes their death. The affected blooms are distinguished from frost injuries from the fact that they cling to the twigs, and gum commonly oozes out from the canker formed upon the twig at the base of the bloom. The small green fruits may also decay at all stages, and the twigs may be killed outright from numerous cankers upon the bark. Such varieties as Triumph and Connecticut frequently begin to rot before they ripen, and the entire crop may be lost even when well sprayed. Such sorts should never be planted. Varieties as susceptible as Champion are not very satisfactory shipping varieties. A thorough system of summer spraying, as outlined under "spraying" (page 2500), should control brown-rot.

Peach-scab is a fungous disease which appears upon the fruits in the form of small black dots. In severe cases these dots may be so numerous as to form a sooty blotch. The skin of the fruit may then crack, offering an excellent opportunity for brown-rot to begin its destruction. Peach-scab is most serious from central New Jersey south to Georgia. Upon hilly areas, north of central New Jersey, it is rather uncommon

2799. The three leaves at a joint, where fruit-buds are forming. Fruit-buds sometimes form in the axil of single leaves, and sometimes on short spurs.

and it seldom requires any attention. The disease occurs only upon the upper surface and ends of the peach as it grows on the branch. It makes its appearance in the form of very minute black spots or dots from about the middle to the last of June upon early varieties in New Jersey, Delaware and Maryland. Farther south it occurs correspondingly earlier. It may be readily controlled by thorough summer spraying with the self-boiled lime-sulfur.

Peach-mildew most frequently occurs along the northern limits of peach-production near the Great Lakes, and in the Northwest. This is probably because of the wider extremes of temperature during the day.

Mildew appears in the form of a white powdery substance upon the leaves and fruit. It may do considerable damage to nursery stock in some cases. Spraying

with self-boiled lime-sulfur will commonly hold it in check.

Spraying.

The peach is subject to the attacks of numerous disease and insect enemies, and thorough spraying is required for success in most cases. The peach foliage is very sensitive to caustic sprays, however, and

2800. Young peach trees pruned, one of them headed back.

great damage may be done from ignorance. Copper sprays, such as bordeaux, are dangerous to use on peach foliage in humid climates. San José scale and leaf-curl can be controlled by a winter spraying of lime-sulfur. Peach-scab and brown-rot can be held in check by several sprayings of the self-boiled lime-sulfur summer spray.

When San José scale, leaf-curl, peach-scab, brown-rot and curculio appear to any considerable extent, the following spraying schedule is suggested:

1. For scale and leaf-curl, apply concentrated lime-sulfur diluted to a specific gravity of 1.03 to 1.04 before the leaf-buds start to make growth in early spring.
2. Just after the petals fall, apply self-boiled lime-sulfur of an 8-8-50 formula and arsenate of lead at the rate of three pounds of paste, or one and one-half pounds of powdered lead to each fifty gallons of spray.
3. Repeat this when the calyces are shedding from the fruits or when the latter are about the size of green peas.
4. Apply self-boiled lime-sulfur without the addition of arsenate of lead three weeks after the third spraying.
5. Apply self-boiled lime-sulfur again three weeks later to all varieties ripening later than Carman.
6. In wet seasons and especially for varieties as late as Fox, Salway, or Bilyeu, an additional spraying may prove profitable.

No spraying should be done within less than three weeks of the ripe stage, or the fruit may have a white-washed appearance.

Where the plum-curculio causes little or no damage, the second spraying may be omitted, and where peach-scab and brown-rot are uncommon, the fourth, fifth, and sixth sprayings may be omitted.

Winter injuries.

There are several forms of winter injury, including bud-killing, twig-killing, collar injury and bark-splitting. Bud-killing takes place when the temperature is too severe in winter. The pistils and stamens are killed in their rudimentary state, giving the center of the bud a brown or black appearance when a cross-section is made. Poorly formed buds often die even

when the winter temperatures are not particularly severe. Alternate warm and cold periods may also result in bud-killing. Varieties such as Reeves, Early Crawford, and Mountain Rose suffer more from bud-killing than Greensboro, Carman, or Crosby. Vigorous trees that ripen their wood-growth early are best able to withstand low temperatures successfully. Trees that make a relatively late growth are, however, more successful in resisting the effects of a variable winter.

Twig-killing is a more severe form of injury than bud-killing, and following such injury the trees should be well cut back before growth begins.

Collar injury is caused by the action of the weather upon the bark of the trunk just at or below the surface of the ground. In mild cases, the inner bark becomes yellow in color and very spongy. The tree is checked in growth and the fruit forced to an unusually large size. The lenticels or dots are large and the flavor of the fruit is often astringent, due to a large proportion of tannin. In more severe cases of injury, the trees suddenly die in midsummer with the shriveled fruit clinging to the twigs. Bark-beetles often attack trees checked by winter injury and the death of the trees is often entirely attributed to their attacks. The Elberta appears to be more susceptible to this form of winter injury than such varieties as Greensboro or Carman. The soil should be firmly mounded up for about a foot against the trunks of peach trees just before freezing weather each fall to prevent such winter injury.

The bark on the trunks of old peach trees may occasionally crack open as a result of winter weather. The most that can be done is to cut away the bark that has separated from the sap-wood and to paint the latter to prevent decay.

Peach trees not infrequently suffer injury to the sap-wood of the branches and twigs, and the trees may fail to grow vigorously the following spring. Such trees should be given liberal fertilizing and be kept well cultivated to promote a good growth. M. A. BLAKE.

Peach-culture in the South.

Peaches have been abundant in the southern states since the very earliest settlement, the so-called Spanish varieties being first distributed by the early settlers in Florida, and to this day, all through the South Atlantic States, the old "Spanish Blood" or "Tinsley" peach, is spoken of as one of the choice fruits of the earth. From time to time all the improved varieties were scattered through the South by the more progressive horticulturists and nurserymen and these and their seedlings were abundant on nearly every plantation. The South being strictly an agricultural country, there was little chance for commercial peach-culture until along between 1870 and 1875, when the introduction of a number of new extra-early varieties of the Alexander type, seedlings of Hale and Rivers, gave such bright showy peaches the latter part of May and early June that attempts were made to market them at a profit in our northern cities.

A lack of quick through railway-express service caused them to be three and four days on the way, and usually to be delivered in poor condition. Occasional lots, arriving in fair to good condition and selling at \$12 to \$20 a bushel, convinced a few of the shippers that the extra-early peaches of the South were appreciated at the North, and persistent efforts were continued to get them to market in sound condition. Every conceivable style of shipping package was used,—paper-wrapped fruit placed between layers of cotton, excelsior, paper, and the like, and sent by express or steamer,—and all brought about the same returns, "Arrived in bad order." Only occasional lots paid a profit. Finally, heavy refrigerator boxes that would hold about six bushels of fruit in packages, and a sufficient quantity of ice, with strong castor wheels under them so they could

be trundled in and out of freight cars, were utilized to bring peaches north by Savannah and Charleston steamers; and by re-icing on the steamers, much of the early fruit came through in good order and sold at such satisfactory prices as to encourage the sending of the large midsummer peaches to market in the same way, and the planting of moderate-sized orchards and the further experimenting with seedlings and varieties best suited to long shipments.

The perfection of the refrigerator car for fruit transportation, improved machinery for the cheap manufacture of ice, the consolidation of various small railway lines into great through routes of transportation, and a full appreciation by their managers of the importance of a successful peach industry, and last but not least, the originating of the Elberta peach by Mr. Rumph, were the final factors in rapidly developing the great commercial peach industry in Georgia, and its smaller counterparts in South Carolina, Alabama, Mississippi, and the more recent rush of overplanting in Texas, Arkansas, Oklahoma, and southern Missouri.

The year 1889 saw the first large peach crop successfully harvested and marketed. Profits were large, and being reported in the press many times greater than they really were, stimulated much planting by those entirely unfamiliar with fruit-culture, and with no special love for it except the money that might be made out of it. Cheap lands and the abundance of good low-priced labor were encouragements to extensive plantings. In nearly every state of the South, land in vast tracts suitable for peach-culture could be had at \$3 to \$10 an acre, and labor from sun to sun at 40 to 60 cents a day; while in 1915 these lands are selling at \$25 to \$100 an acre, with a possible average of \$40, and labor costs \$1 a day or more, while the added expense of three or more sprayings each year has helped to double the cost of peach-production in the South.

Along the Atlantic and Gulf coasts, varying from 100 to 200 miles inland, most of the land being low and flat, early blooming, followed by spring frost, makes the peach industry too uncertain to be profitable. The hill lands in western sections of Atlantic Coast states, and northern sections of the Gulf States, is really the peach country of the South, where extended lists of varieties are grown, covering a season of fully two months; while the southwestern states, planting almost entirely of one variety, have a season of less than two weeks in many orchards. Fort Valley and Marshallville, the great peach centers of Georgia, though on tablelands about 200 miles from both ocean and Gulf, and at an elevation of a little over 500 feet, are not in what might strictly be called the hill country, being just below the southern edge of it. In this section of Georgia, most of the peach orchards have been planted on old cotton-land, much of which has been in cultivation a century or more, and while the surface-soil is worn and poor, down deep in the red clay soil underlying the 6 or 8 inches of sandy gray loam of the surface, there must be a vast amount of fertility from the way peach trees grow when once started and a reasonable amount of culture is given.

In the early days most of the orchardists, who were cotton-planters as well, planted second- and third-class yearling trees, or else small June-budded trees any time from October to March, opening furrows for the trees and cross-checking the rows 18 to 22 feet apart, later plowing this land and planting it in cotton, continuing it for three and often four years. Two to four hundred pounds of low-grade fertilizer is applied in drills for the cotton and usually very thorough culture given; trees are allowed to grow at will, their culture being incidental to the cotton crop. In such orchards very little if any pruning was ever attempted. After the trees become so large as to drive out the cotton, one plowing is given in winter, then anything from fairly good culture to none at all the remainder

of each season. Such a system resulted in many "scrub orchards," that were not very profitable after six or seven years.

In the recent and more highly developed peach orcharding of this section of the South, better preparation is given the land at the start, dynamiting of the holes for planting being largely practised. There is a more careful selection of trees, far more liberal fertilizing, planting at greater distances, seldom less than 20 by 20 feet, better culture, less and less of intercropping, except of cowpeas and other cover-crops, and somewhat more of systematic pruning, though as yet this art is not fully enough practised to show best results. Many of the land-booming orchards, planted between 1890 and 1900, proved financial failures and are either no longer in existence or else have been absorbed into other and better propositions. There are less and less of the cotton farmer orchardists and more peach specialists, as time and experience have shown the business to be unprofitable, except under best business conditions. The writer's plantations, which ten years ago aggregated some 265,000 trees, have now been reduced to less than 100,000 trees, as only by planting at greater distances and giving a less number of trees better care and attention, can any profit be assured.

All land is plowed deep, and sometimes subsoiled before planting. Young orchards are given frequent and thorough tillage up to midseason, when two or three rows of cowpeas are drilled in at least 4 feet away from the rows of trees; these and the trees are cultivated frequently, until the peas have taken almost full possession of the ground, and it is time for both the land and trees to have a rest from cultivation. In the fall when peas are ripe, enough are gathered for next year's seed, after which hogs or mules may be turned in to pasture for a time. The stubble furnishes a fine winter cover, and is turned down at first plowing in February or March, when summer culture begins, and at proper time the orchard is again seeded to cowpeas, across the former direction of the rows. Three years of this usually builds up a perfect orchard without the aid of any other fertilizers, except possibly a very little about the trees at time of planting to give them a start.

Low-headed trees are the rule, the trunks seldom branching over 18 inches up, and often 8 inches to

2801. Before and after pruning.

a foot from the ground. As a rule, the close cutting-back at time of planting, and a general shortening-in of the leading branches for the first two or three years, is about all the pruning given, even in the best orchards. A good plan is to shorten-in every year much of the past season's growth, and from the central head after cut back two or three seasons' growth; but under no circumstances are any of the good side shoots cut out

that force themselves on all the main stems when the top is properly headed back. These little side branches have given several full crops of fruit, when without them there has been failure.

Soil and climate favor the very brightest of color on all peaches in the South; qualities of the soil and the long, hot summer sun give a richness and sweetness of flavor superior to any other section of America, though the same varieties are not so juicy or luscious as when grown farther North.

The orchards in connection with cotton plantations run all the way from 10 to 100 acres in extent, while the "straight-out peach farm" seldom has as few as 50 acres in fruit, more of them having from 100 to 200 acres, while orchards all the way from 300 to nearly 1,000 acres in extent are no uncommon sight. The Georgia peach industry turns out 5,000 to 7,000 carloads of peaches in seven or eight weeks of a busy picking season, even though the 18,000,000 trees estimated to have been in that state ten years ago have now been reduced to less than 8,000,000.

Growth usually ceases early in August, and the trees shed their leaves the last of September, a month or six weeks before any frosts occur. Should the fall be warm and wet, some fruit-buds will be forced into bloom, while the greater number will remain dormant until late January or early February, when spring growth commences. The season of full bloom is usually about the first week in March, though it varies all the way from February 15 to March 25, and no matter whether early or late, the entire blooming season of most varieties covers a period of nearly three weeks. While spring frosts are the greatest menace to southern peach-culture, this long blooming period often gives a chance for a setting of fruit between the various frosts, or after the last one, from some belated buds. Even with these varying chances of escaping between frosts, about one year in three frost destroys the peach crop in some one or more of the great centers of peach-production in the South.

Two other serious troubles hamper the southern peach cultivator—curculio and monilia or brown-rot. Curculios are very abundant; beginning early in April, they keep up their destructive work until the end of the fruiting season. In recent years in the summer spraying for monilia, the addition of arsenate of lead has controlled the ravages of curculio so well that now they are far less destructive than before. The early spring months at the South are inclined to be pleasant

and very dry, and the summer rains, which are frequent and abundant when they do come, often do not set in until the latter part of July or early August, near the end of the peach-shipment season. Often, however, they begin in June, and continue for two or three weeks, and in the case of the season of 1900 it rained for six weeks through the main part of the peach harvest. Hot sun between showers and the general mugginess of a warm climate rapidly breed the monilia fungus, and brown-rot is the most serious trouble the southern peach-grower has

2802. A bad form of top.

to contend with, though with proper spraying it may be held almost entirely in check, and except for the extra expense is not now to be feared as in the earlier days of southern peach-culture. In the ten years from 1895 to 1905, probably more than 50 per cent of peaches grown in Georgia rotted on the trees, or else

reached market in specky condition as the results of monilia fungus.

The first great crop of Georgia peaches that made a strong impress on all northern markets was in 1889, when the Elberta variety by its large size, great beauty, and fine keeping qualities showed up so strongly for the first time as to outclass all other varieties. Great profits were made and, being reported as even greater, there was a mad rush to plant Elberta, and Elberta only. This was kept up until 1896-7 before it came to be realized that there could be too much of even a good thing. The rushing of a great volume of fruit, no matter how choice, into the markets in two or three weeks, before they had been "toned up" to at least a liberal supply of good fruit, was a business mistake. To remedy this there has been a hunt after a good early variety to precede the Elberta, as well as later ones to follow it. So that, while prior to 1896 more than 75 per cent of the plantings were of Elberta, since that time not more than 15 to 20 per cent of Elberta have been planted. There is a better balance of varieties, and a longer and more profitable season of marketing has been assured. Many early and mid-early varieties growing ten or fifteen years ago have mostly been abandoned, Greensboro, Carman, Hiley and Belle (of Georgia) being varieties most largely grown to precede Elberta. Growers are now beginning to abandon the Greensboro and plant excessively of other extra-early varieties, notably Unedda, Arp (Arp Beauty or Queen of Dixie), and Early Rose. These varieties having sold at extremely high prices in recent years, there now appears as great a tendency to plant extra-early ripening peaches as there was for the Elberta in the earlier days.

When loading in cars, the crates are placed side by side about 2½ inches apart across the car, taking seven crates. Then two strips of inch-square stuff, just long enough to reach across the car, are put on top of the crates at each end and are lightly nailed down. Tier upon tier is built up in this way, either five or six crates high, until the car is full. Spacing of the crates and the slatting provides space for cold air around each and every crate. In dry seasons, when fruit is free from rot-germs, cars as now constructed can with safety be loaded five crates high, but in wet seasons, with rot prevalent, they arrive in market in much better condition when loaded only four high. Besides the original icing, which requires four to six tons to a car, a re-icing after loading takes one to three tons, depending upon how long the car is loading. A car will hold 448 to 525 crates, according to the size of the car and whether loaded four or five crates high. Handled along best modern lines, with careful inspection from start to finish, it costs for the six-basket Georgia carrier, from 30 to 35 cents to take peaches ripe from the tree and place them in the car.

Some peaches of the Crawford type are grown all through the South, but they do not succeed so well as most others of the Persian strain, and none of the Persians does so well in the far South as the North China strains, to which Carman, Hiley, Early Rose, Belle, and Elberta belong. The South China peaches, to which the Peen-to, Honey, and Angel belong, succeed best in Florida and close along the Gulf Coast. While their bitter-sweet flavor is appreciated by some, they are not generally profitable for market.

In preparation for marketing the fruit crop, many of the large orchards have railroad side-tracks running to their packing-houses in the orchard; refrigerator cars are brought South, and every available bit of side-track for 300 or 400 miles about is filled with these cars. At leading centers, refrigerator-car people have constructed great ice-storage-houses, with every convenience for quickly icing and re-icing cars. Agents of these refrigerator-car companies, by frequently driving about among the orchards and keeping in touch with the managers, plan to have enough cars iced and

cooled off so as to be ready for each day's demand, and by placing an order with the railroad agent the night before, the orchardist may have one or a dozen refrigerator cars delivered on his side-track in the morning. For smaller shippers, who cannot load in carlots, the railroads keep at all times in season refrigerator cars on siding at each station in the peach district, into which any number of shippers may load; more often there will be a number of such cars loading at the same time, so that a shipper may have a choice as to which market he will consign his fruit. Except in the height of the season, these cars are often two and sometimes three days in loading, and the continued opening of the car to put in small lots of fruit prevents perfect refrigeration; consequently fruit from small shippers more often goes to market in bad order than from the larger orchards, where a car can be quickly loaded and at once closed up, not to be opened until ready for sale in some northern market. In the Hale orchards, a car is often loaded in an hour, and very little of the fruit is ever so long as two hours passing from the tree through the assorting- and packing-houses to the car.

In some of the smaller orchards, fruit is packed in crates or baskets under the trees, and then hauled in open wagons, often without springs, to the railroad station. In others, some of the old farm buildings are used as packing-houses; more often special fruit-houses are used, their size depending upon the requirements of the orchards, while in style and convenience more depends upon the intelligence of the orchardists and desire to handle the fruit rapidly in best possible manner. The picking-basket most generally used is a shallow, round basket, with a drop handle, and holding about a half-bushel. With good refrigerator cars and prompt railroad service, fruit is now allowed to come to full maturity on the tree, and is picked just before it begins to soften.

Since the organization of the Georgia Fruit Exchange, some eight or ten years ago, about 75 per cent of the peach-growers of Georgia, Alabama, and South Carolina have, through this coöperation, been enabled to secure a wider distribution and a more uniform market-price for their products, and their business is on a more secure foundation than in any other section of the South.

J. H. HALE.

Peach-growing in California.

The peach is a fruit of wide commercial importance in California. The great peach-growing sections are principally in the San Joaquin and Sacramento valleys, but orchards are found and are profitable not only in the mountains up to an altitude of 3,000 feet, but also in the coast sections. The most important districts are the first named. For size, flavor, color, and shipping qualities, the peaches grown in this state have a national reputation.

The tree thrives not only on the sandy, loamy soils which are adapted to irrigation and are well drained, but also on the heavier red and black soils, which are more or less mixed with gravel and are found both in the foothill and coast regions of California. On account of the arid climate, there being no rainfall from May until October, it goes without saying that to produce high-class peaches for either shipping, canning, or drying, irrigation is very essential. The theory that was formerly advanced that irrigated fruit would not keep, has not been borne out in practice, and to attempt to grow peaches without irrigation, particularly in the great valleys, would now be considered the height of folly.

No systematic plan has been followed in fertilizing orchards, although growers are realizing that to grow good fruit and to maintain an orchard up to the very highest standard, the application of fertilizers is essential. Considerable interest is now taken in cover-crops,

and a number of experiments have been made with Canada field peas, fenugreek, and vetch. To grow a cover-crop successfully, it is necessary to have water in the fall, and as water from the canals is not obtainable, it must be secured by pumping. Barnyard manure, when it is to be had, is given the preference by growers. This is becoming very scarce, however, and eventually commercial fertilizers will come into general use.

2803. A good two-year-old peach tree.

Peach trees are transplanted in California when they are one year old from the bud, except in years when stock is scarce and trees sell at high prices, when many growers purchase June buds, which transplant readily, providing care is taken to allow them to mature fully in the nursery before digging.

Nothing will bring a peach tree to a premature end more quickly than not to prune. Trees when transplanted to the orchard should be pruned both root and top. The root-pruning should be the shortening-in of all the roots at least one-third and the removal of all bruised and lacerated roots.

After the trees are set, they should have the top cut off to within 20 inches of the ground, even if the tree be 6 feet or more in height. In most cases, the failure of trees to grow may be attributed to the orchardist's failure to observe this simple rule. It is very necessary to settle the soil around the tree, either by irrigating (running the water in furrows), or by tanking (using not less than fifteen gallons of water to a tree).

The winter following the planting in the orchard, the branches forming the head should be confined to not more than five at the very outside, and four is better. These should be cut back at least two-thirds and all laterals removed.

This pruning will not only cause the trees to grow stocky, but it will probably also serve the purpose of making the framework branches very sturdy. The tree will respond by making an immense growth and in the second winter the shortening-in of this growth will again have to be very severe, and thinning will have to be practised. The point to be considered in this case again is to give the tree not only the goblet form, but to perfect it, for this pruning increases its vigor

and makes it capable of producing heavy crops which are well protected from any injury by the sun, due to its wealth of foliage. From the third year, two or three laterals are allowed to grow on each of the frameworks, and their growth is again shortened-in severely. In the fourth year, the pruning need not be so severe, and a reasonable crop of fruit may be expected. Pruning in after years should be followed out regularly each season if good crops are to be secured and the longevity of the tree maintained.

It is a mistake to plant peach trees too close together. In former years it was customary to plant 20 by 20 feet, but now trees are planted 24 by 24 feet, as better results have been secured at this distance.

Thinning must be practised when the crop is heavy, for, if not followed carefully, the fruit will lack size, and no matter for what purpose it is used it will go into an inferior grade and at prices which would be very unsatisfactory to the grower. The peaches should never be closer than 4 inches apart. If the ground underneath the tree has the appearance of being covered with a green carpet from the effect of the thinning, it is evidence that the work has been well done.

When shipped fresh, peaches are wrapped in soft paper and packed in twenty-pound boxes. The number

2804. Peach-packing. The Climax basket.

of peaches shipped out of California is about 2,200 carloads annually. For local consumption in the larger cities, the peaches are shipped in open lug boxes, holding about forty pounds.

The free-stone peaches are the only ones dried, as a rule. These are first halved, the pits are removed, and the fruit is placed in trays. The drying takes place in the sun altogether. Before drying, the peaches are exposed to the fumes of sulfur for not less than four hours. This not only kills any insect life but gives the peaches a much more appetizing appearance. The very heavy tonnage of dried peaches, averaging 30,000 tons annually, would be utterly impossible to handle unless the same could be dried by exposure to the sun's rays. It requires from six to seven pounds of fresh peaches to make one pound of the dried product. Many persons object to the fuzzy skins on the dried fruit and in recent years peeled peaches have been in the markets in a limited way. The method of peeling has been to expose the halved peaches to the sulfur fumes for several hours. This loosens the skins and they peel off readily. This handling of the fruit is expensive, however, and with the difficulty of securing labor, it has not been practicable except on a small scale. This method has been very much improved, however, and the peaches after being halved are now dipped in a hot lye bath for fifty seconds, using about one pound to ten gallons of water. The peaches are then given a bath in cold water, not only to remove

every vestige of lye, but to cause the skins to slough off. Peaches treated in this way sell at twice the price of the unpeeled peaches and the entire character of the fruit is changed. Outside of the lye bath, which is the only additional treatment the fruit receives, the process is the same as is followed when the peaches are not peeled.

The canning of peaches is another important branch of the industry, the output from California being in the neighborhood of 84,000 tons annually. This work is conducted exclusively by commercial concerns having every modern appliance to handle the fruit expeditiously and turn out uniform grades. Outside of the halving of the peaches, which work is done by women, the work is accomplished entirely with machinery. Sanitary cans are used as containers and a limited quantity of the fruit is placed in glass jars. The commercializing of the industry has created a demand for well-defined standards. To illustrate this, the only peaches which are regarded as the leaders by the canning trade are the clings; and in the list of varieties, the Tuskena, Orange, and Phillips, all of which are yellow, are in the heaviest demand. Peaches that have no red at the pit are preferred for canning, as the syrup never becomes discolored. The important place which the canning industry occupies in the peach business will be sure to bring about improvements in varieties to meet the demand for peaches with smaller pits, finer-grained and more highly flavored flesh. Already several new varieties, mostly chance seedlings, have been introduced and are attracting considerable attention. For shipping, Alexander, Briggs (Red May), Early Hale, Dewey, Imperial, Sneed, Elberta, and Salway are recognized as standards; for drying, Elberta, Foster, Late Crawford, Lovell, Muir, Susquehanna, and Wheatland; for canning, Tuscan, Runyon, and Seller (Orange) Clings, McDevitt and Phillip and Levy (or Henrietta).

Fortunately, the California peach orchards have never been threatened with insect pests or diseases that cannot be controlled. The crown root-borer is troublesome, in some sections, but it has always been under control. The San José scale is no longer regarded as a very serious pest, for it is held in check by predaceous insects and by spraying with lime-sulfur washes. Leaf-curl in some years gives considerable trouble, but if the trees are given a thorough spraying with bordeaux, it is easily controlled.

The average life of a peach orchard is twenty years, but there are many profitable orchards much older than this, when they have received good care.

A failure of a peach crop has never been known in California, and although in some years the crop has been curtailed by late spring frosts, growers have never practised smudging to any extent.

GEORGE C. ROEDING.

Protecting peach trees in cold climates.

Numerous ways of protecting peach trees from the effects of trying winter weather have been devised. Such plans include the placing of a protective covering about the trunk and branches of the tree. Cornstalks, straw, hay, evergreen boughs, and similar materials may be used for this purpose. Some persons have tried the plan of laying the tree on the ground in an effort to make the work of covering easier as well as more effective.

Peach trees may be laid on one side with comparative ease and without much injury, providing the process is begun when the trees are small. The root-system is manipulated at this time in such a way that most of it extends in two opposite directions. This is accomplished by cutting the roots, beginning when the trees are small, preferably the first winter after planting and thus accustoming them to the operation from the beginning. If this plan is followed from the start, a

little work with the spade will suffice to lay a tree down. Once on its side, the branches should be gathered together with twine and the covering put in place and weighted down.

An interesting method of laying a tree down without disturbing its roots was devised a number of years ago. This is accomplished by bending the newly planted tree over to the ground, where it is fastened. The side branches are cut off at first as fast as they appear, thus inducing a long straight growth. After the prostrate stem has attained a length of 10 to 12 feet, an upright top is allowed to develop. At the approach of winter, the top of a tree trained in this manner can be pushed over easily, as the long prostrate trunk serves as a lever or pivot. The long exposed trunk will need to be protected at all times from the effects of the sun. This is easiest done by using an inverted trough made of light boards.

The process of laying trees down under irrigated conditions is somewhat simplified, as the ground can be made very soft by the use of water. Here, again, the work should be begun the first winter after planting. The ground about the young tree is first saturated with water from the irrigation ditch. The trees are then pushed over in the direction that offers the least resistance. After the branches have been drawn together with cord, they are covered first with burlap, then with a light coating of earth. As the trees become more mature, a basin about 4 feet in diameter is made in the earth about the trunks before the water is turned in.

The nicest of judgment must be used in removing the covering in the spring, as a little too much warmth or a slight exposure to cold may mean the loss of the year's work. At the first sign of swelling buds in the spring, the earth covering must be lightened during the middle of the day and replaced for the night. As growing weather comes on, still more of the covering is removed and a certain amount put back each night until the tree is raised for the summer. The danger of damage by cold continues until the fruits have attained considerable size, consequently the work of uncovering in the middle of the day and of covering for the night extends through a comparatively long period.

After the danger of damage by frost is passed, the ground is again irrigated and the trees are raised. Trees so handled are unable to support themselves in an upright position, consequently they are supported at an angle by props. It is estimated that the entire labor of laying a tree down, covering and of raising again in the spring, can be done at a cost of 50 cents a tree.

W. PADDOCK.

PEANUT (*Arachis hypogæa*). Popularly the peanut, as the name indicates, is called a nut, but it more properly falls into the class of grain or forage crops. The fruit or "nut" is really a pod, comparable with a bean-pod or pea-pod. The plant is related to beans and peas. The seeds (comparable with bean seeds) furnish excellent food for man as well as for his beasts and fowls, and the cured tops make an excellent hay or forage. The peanut is usually not classed with horticultural crops; for a fuller account, see Vol. II, "Cyclopedia of American Agriculture."

Commercially, the peanut is not grown north of the latitude of Washington, D. C., but on the sandy and loamy soils to the south and west of the above-named city, on lands that have recently been limed, it may be used as a rotation or as a special money crop. North of this territory the plant can be used with profit as a forage for hogs, although only a portion of the pods set will come to maturity. As a garden plant, the peanut can be grown as far north as central New York, but only a few pods will actually mature seeds, except in long warm growing seasons.

There are two general types of peanuts: those known as bunch nuts, and as vine or trailing nuts. The bunch

nuts are most desirable because the tops can be more easily harvested for forage, the rows may be closer together and the distance between the plants in the row may be less than with the vining types. The cultivation as well as the harvesting (digging) is easier. The bunch type of nuts, such as the Spanish and Valencia, may be planted in rows 30 to 36 inches apart, with the seeds scattered 6 to 10 inches apart along the row. The large-seeded thick-shelled nuts require to be shelled before planting in order to insure satisfactory germination, but the smaller thin-shelled sorts may be planted whole and a good stand secured. The planting season, as well as the field care of peanuts, is practically the same as for corn. They are tender to frost and grow best during warm weather. The vines will be killed by the first frosts, but when desired for forage should be harvested in advance of that date. As the pods or nuts are borne beneath the surface of the soil, the crop is harvested by lifting or plowing out the whole plant, separating it from the earth and curing the plant and pods together by stacking them in tall narrow stacks built up around a slender stake about 6 feet high, at the bottom of which cleats 3 feet long have been nailed in such a way as to keep the plants off the ground. The stacks are so built as to cause the vines to protect the nuts. The roots with the nuts attached are placed next to the stake, with the tops out. This method permits the nuts to be cured slowly and without discoloration or staining that would result were the nuts exposed to the weather. The plant is a most interesting one, both horticulturally and botanically, and is at the same time an important economic crop as well as a garden novelty.

L. C. CORBETT.

PEAR. A popular fruit and tree of the genus *Pyrus*, long cultivated and much modified.

The cultivated pear, as known in North America, is derived from two distinct sources, the European *Pyrus communis* and the Oriental *Pyrus serotina*. Pears of the European stock have been grown in North America from the earliest settlement of the country. They thrive particularly well in the New England states and New York, and west to the Great Lakes, and again on the Pacific slope. In the great interior basin, pear-culture always has been precarious, due primarily to the great liability of the trees to blight.

In the southern states, the climate is too hot for the best development of the tree and the best quality of the fruit. In the north prairie states, the winter climate is so severe that the pear tree will not grow. Forms of pears are shown in Figs. 2806 and 2807, as representing the common species.

Some time before the middle of the preceding century the sand or Chinese pear (*Pyrus serotina*, formerly and, as it now appears, erroneously, identified as *P. sinensis*), Fig. 2808, was introduced into the eastern states, although it attracted little attention. It soon hybridized with the common pear, and a race of mongrel varieties was the result. Of these hybrids, only two have gained great commercial prominence. These are LeConte and Kieffer (Figs. 2809, 2810, 2811). The LeConte, which appeared about the middle of last century and which is the first of the American hybrids, so far as we know, was found to be well adapted to the southern states and its general introduction there after the close of the Civil War was the beginning of commercial pear-culture in the South. It was first supposed to be blight-proof, but, in later years, orchards have been nearly decimated by the

2805. Cluster of pear flowers (*Pyrus communis*). ($\times \frac{1}{2}$)

blight, with the result that the LeConte is gradually lessening in importance and its place is being taken by the Kieffer, although the latter is by no means blight-free. The Kieffer pear originated with Peter Kieffer, of Roxborough, Philadelphia, an Alsatian gardener, who died in 1890. He grew the Chinese sand pear or Sha

2806. Bartlett pear. The pyriform or "pear-shaped" form of fruit. ($\times \frac{1}{2}$)

Lea and sold the seedlings as ornamental trees, for this species is of very distinct and handsome growth and the fruit is ornamental and fragrant. Alongside the sand pears were Bartletts. Amongst one of the batches of seedlings from the sand pear he noticed a plant with different foliage, and this he saved. Its fruit was found to be superior to the sand pear, and it was introduced as the Kieffer. It fruited in 1873. The Kieffer pear is now very popular in many parts of the country because of its great vigor, healthiness, productiveness, and the keeping qualities of the fruit. In point of quality, the fruit is distinctly inferior, but it meets the demands of the market and is an excellent fruit for canning.

Pyrus serotina itself bears a very hard pear which is inedible in the raw state, but it is excellent when used as quinces are. It is fragrant and ornamental. The tree is a most vigorous and clean grower. The plant is well worth growing as an ornamental. It is used for stock for ordinary pears, particularly in the southern states. For an historical and horticultural account of the oriental pears and their hybrids, see Bulletin No. 332, Cornell Experiment Station, by Cox (under direction of the late John Craig).

In the cold prairie countries and other parts of the cold north, Russian pears have gained some headway in recent years. These are hardy types of *Pyrus communis*. The fruit is usually of low quality, but the trees are considerably harder than the ordinary pear.

Pear-culture is the one American fruit industry which seems to show little expansion. Pears are not a popular dessert fruit in this country, and the product is largely used in canning. This is a great pity, and a loss to the people. The cultivation of the Kieffer on a large scale has probably bred a generation of people who are little aware that the pear is a fruit that may be good to eat out of hand; and the commercial and cultural difficulties are greater than with other fruits.

The pear thrives on a variety of soils, but it succeeds best on those that are rather hard clay. On sandy and loamy lands it tends to be short-lived. This is perhaps due, in part, to the fact that trees grow rapidly on such lands, and are, therefore, more liable to the attacks of blight. It is now generally accepted that trees which are making a strong and soft growth are more susceptible to blight than those which grow rather slow and firm,

although all trees are liable to attack. Some varieties are more nearly immune than others. Caution must be exercised, therefore, in the tilling of the pear orchard. Whilst pears profit by the best tillage, as apples and potatoes do, it is easy to carry the tilling and fertilizing so far as to produce too vigorous growth and thereby invite the blight, and this disease is the one great menace to pear-culture. Therefore the most careful pear-growers use sparingly of stable manure and of nitrogenous cover-crops. They prefer to supply fertility by means of concentrated fertilizers which are not very rich in nitrogen. If, however, the trees are not making a strong and steady growth, it is as necessary to apply nitrogenous fertilizers to the pear tree as to any other.

In the interior country, pears are likely to suffer from sun-scald, and therefore the tops are started very low, usually not more than 2 or 3 feet from the ground. Standard pears (those not grown as dwarfs) are pruned much as are apple trees, except not so severely. Heavy pruning may open the top and invite sun-scald, and it also tends to make too strong and sappy growth. After the top of the pear tree is well formed and established, it is customary to do little pruning, only keeping the top fairly free and open.

The pear bears mostly on spurs which continue to branch and to bear for a number of years, and in pruning it is important that these spurs be not removed unless it is desired to thin the fruit. The flowers are borne in umbel-like cymes (Fig. 2805), but in most kinds only one fruit sets in a cluster. Pear trees are usually planted much closer than apple trees. The customary distance is 18 to 20 feet. Fig. 2812 shows an average east-American pear orchard. Fig. 2813 is a picking scene.

Many of the varieties of pears are infertile with themselves: they need the pollen of other varieties to cause them to set fruit freely. Probably any variety will fertilize any other variety in case the two bloom simultaneously. Such varieties as Kieffer and Bartlett are usually classed as self-sterile kinds, but the degree of sterility varies in different places and with different conditions. The safest plan in the setting of a pear orchard is to plant not more than two rows of one variety together, and to alternate with one or two rows of another variety.

Good varieties of pears are numerous. The one most important variety is the Bartlett (Fig. 2806), which was early introduced into the United States from Europe,

2807. The globular or apple-shaped form of fruit.—Idaho pear.

where it is known as the Bonchretien. At present, the Kieffer probably holds second place. In the eastern states, the Seckel (Fig. 2814) is a prominent variety, and is the standard of quality. Other prominent varieties are Anjou (Fig. 2815), Clairgeau, Hardy, Howell, Sheldon, and Diel. The list might be almost indefinitely extended. In the Gulf region, the oriental hybrids

alone are successful, and the leaders are Kieffer, LeConte, Garber, and Smith. The most notable pear of early American origin is undoubtedly the Seckel, which originated near Philadelphia in the eighteenth century. As late as 1880, the tree presented the appearance shown in Fig. 2816, which appeared (in larger size) in the *Gardener's Monthly*. In 1908, all that remained was a dead and decayed stump (Fig. 2817).

The season of the maturity of pears runs from mid-summer, when it is introduced by Summer Doyenne and (Manning) Elizabeth, to late winter, when it is closed with such late winter varieties as Nelis (Winter Nelis), Malines, and others. The winter pears are relatively little known in the eastern states. As a rule, they come into bearing late or are not very prolific; but there is no reason why they should not be better known. Winter pears are kept as are winter apples, although somewhat greater care is necessary. They should be stored in a uniformly cool temperature. If allowed to hang too long on the tree, they become over-ripe, and then if placed in an ordinarily warm cellar, they do not keep more than one or two months.

Unlike most other fruits, all pears are greatly improved in quality if they are ripened indoors. They should be picked as soon as they have reached their full size and have begun to color, but before they have become soft, and be placed in a dry and rather cool room. If the wind is allowed to blow over them, they are likely to shrivel. If kept too warm, they ripen too quickly and soon rot. The best quality is secured when they are picked about two weeks in advance of their normal ripening.

Pears are marketed much as are apples, although the barrel is little used for the dessert varieties. For export, as well as for a good home trade, the following sentences by George T. Powell are useful: "The fruit should be gathered when it has reached its most perfect development, but not allowed to come to its full maturity or approximate ripening. This is the right condition of fruit when it is to be shipped without refrigeration. With refrigeration, a little fuller maturity may be allowed. Each specimen should be wrapped in paper. A layer of excelsior should be placed on the bottom of the box, which is marked to be opened; over this place a sheet of paper. Pack the pears in single layers, covering each with paper and excelsior until the box is filled, nailing cover securely under considerable pressure. Boxes should hold thirty-six large pears, and sixty of medium size. [Fig. 2818.] This is a refinement of even the best packing for the common domestic trade. [Fig. 2819.]"

Dwarf pears.

When worked on the quince root, the pear is easily grown as a dwarf. The free stocks—those grown normally on pear roots—are known in this country as standards. The dwarf pear comes into bearing earlier, and, since the trees are small, the fruit can be thinned and the trees sprayed, and the fruit therefore should be of the highest quality. Dwarf pear trees require more care than the ordinary standards, however, and they should not be planted unless the cultivator understands this fact and is willing to give the attention that they need. Although the trees are by nature dwarf, since they are worked on a smaller-growing species, they nevertheless tend to become half standard if left to themselves. Therefore they must be very severely headed-in every year. A dwarf pear tree should never reach a greater height than 12 feet. To keep it down to this stature, from one-half to two-thirds of the annual growth is removed late each winter. The trees are often planted as close together as 10 feet each way, but this is too close. With the ordinary broad-top pruning, which nearly all American growers give, 1 rod apart each way is not too great. A good dwarf pear tree is one in which the union with the quince stock is very

close to the ground. When the tree is planted, this union should be 4 to 6 inches below the surface after the ground has settled. This deep planting prevents the breaking of the union and places the quince beyond the reach of borers. If planted deeper than this, the pear cion may throw out roots of its own; in fact, it sometimes does this if planted only 6 inches deep. This rooting of the stock is no particular disadvantage, although the tree thereafter tends to grow stronger and greater pruning is necessary. An expert grower can pick out the trees which are rooted from the pear stock by their more vigorous growth: if he desires to check this redundant growth he may cut off the pear roots. It is the common opinion that dwarf pear trees are

2808. The sand pear.—*Pyrus serotina*. ($\times \frac{1}{3}$)

short-lived. This may be true as regards the greater number of specimens which one sees about yards and on untilled areas, but a dwarf pear orchard on good well-drained ground, which is well-tilled and given regular pruning, will last a lifetime. Many varieties of pears do well when grafted on the quince root, but the one that is oftenest grown as a dwarf is the Angouleme (Duchesse d'Angouleme). (Fig. 2820.) This is a large pear of irregular shape which sells well because of its size, but it is of indifferent quality and may not be good enough for a special or personal market. Other varieties popular for dwarfs are Louise Bonne, Anjou, Clairgeau, Elizabeth, and, to a less extent, Bartlett and Seckel. Even Kieffer is sometimes dwarfed with satisfactory results. The growing of dwarf pears is a special practice; in general it is not commercially profitable.

Writing on dwarf pears from a long experience in New York, L. T. Yeomans says: "The soil best adapted to dwarf pears is a rich loam, with a subsoil that requires thorough underdraining—a tile drain within 5 feet of every tree in the orchard would be thorough draining. The soil should be good strong corn or potato ground, and kept in such condition of fertility from year to year, for which purpose good well-composted barnyard manure has no equal, but may be supplemented by other fertilizers—as ground bone and potash. Small crops, as beans and potatoes, may be grown between the trees the first few years after planting, but never should they be allowed in the least to interfere with thorough tillage, or to rob the trees of proper and desira-

ble nourishment. The growth of the tree is of far greater value than any farm crops which can be grown between the trees. The soil should be thoroughly cultivated at least every ten to fifteen days during the growing season till about August 15 to September 1. It should cease in time that the wood may fully ripen. Suitable cultivation can hardly be given with any crop on the ground, except, possibly, when sufficient space is left without a crop next to the trees.

"The trees should be planted in rows 15 feet each way, or in rows 20 feet apart each way, with one tree in the center of each square. As the trees become older, the entire ground should be given up to frequent cultivation; and under no conditions should a dwarf pear orchard be seeded to grass, unless to clover for the purpose of plowing it under for fertilization.

"Dwarf pears require thorough annual pruning, which may be done at any convenient time after the falling of the foliage and before the buds become in the least swollen in the spring; but, where the cold is severe, it is better not to prune till about the first to middle of March. This pruning should begin with the first year, and be continued annually during the life of the tree, cutting back all of the growth to within four to eight buds, and thinning out all surplus branches which will not be wanted for limbs to the tree, so that at maturity the tree shall be open-headed, with opportunity for plenty of air and sunshine all through the tree, without which superior quality of fruit cannot be grown. The lower limbs should be within 20 to 24 inches of the ground. Trees when twenty to fifty years old should not be more than 12 to 14 feet high, and the diameter of the branches about 12 to 16 feet. [See Fig. 2821.] It is a very erroneous impression that a dwarf pear orchard under proper conditions is short-lived. There are in the United States orchards in vigorous condition, and now producing annual crops, that are from thirty to fifty years old.

"Some of the advantages of dwarf over standard pears are: more trees can be planted to the acre, they commence bearing much younger, the fruit is not so liable to be blown off by early winds before maturity, it is much more quickly and easily gathered than from high

2809. LeConte pear. ($\times \frac{1}{4}$)

trees, the fruit is larger and of better quality than that on standards. All varieties do not succeed equally well as dwarfs, because they do not all form an equally perfect union with the quince. Angouleme is the leading and most profitable variety now grown as dwarf, although many others succeed well."

Pears in the prairie region.

On the northern plains, the culture of pears follows the general lines of pear-growing in the Atlantic states, but there are some radical points of difference. According to C. L. Watrous, "The difficulties of pear-growing in the upper Mississippi Valley are many and grievous. Above the 40th parallel and west of the Great Lakes, nearly all efforts have been failures. The best suc-

cesses have been on high rather steep ridges and bluffs near watercourses, with light-colored clay soils and northerly exposures. Pear trees are not planted to the bottom or to the top, but in belts midway around the slopes. Plums may be used lower down and cherries above. The ground should be already set in clover or blue-grass. Small circles are spaded out for the trees. These are cultivated with the hoe and widened with the growth of the tree. Small trees branched very low are best. The trees may be cut back the second year to within a few inches of the ground. Only a very moderate annual growth is desirable. Use no manure until the tree has borne several crops of fruit, and then only with extreme care. Rich black soils, plenty of manure, and clean culture are deadly to pear trees in this region. The critical period is that of the first fruit crop. The deadly enemy is blight, which is sure to appear then. The successful pear-grower must not neglect his orchard a single day during the season of blight, but watch for the enemy and cut out and burn every blighted twig as soon as seen. Sultry damp weather in June is most critical. Such varieties as Warner, Longworth, Vermont (Beauty), Koonce, and Kieffer are said to succeed farther north and resist blight better than any others. Under slightly more favorable conditions, Clairgeau, Howell, Seckel, Tyson, Washington, and Flemish (Beauty) may be used. The hardiest and blight-resistant varieties may be grown, and when in bearing a branch or two grafted with a more delicate sort with success."

Insects and diseases.

The insect enemies of the pear are numerous, but, with two or three exceptions, are not very serious. The tree is attacked by borers, although to a less extent than peaches and apples. These are kept in check by digging them out once or twice a year as on other fruit stocks. The fruit is attacked to some extent by the codlin-moth, but the arsenical sprays keep this insect in check. Of late years the psylla, attacking the growing parts, has been very damaging in parts of the East, although it is irregular in its outbreaks. It can be controlled by thorough work with a spray in winter and also when the blossom-buds are expanding, at the former time by the use of "Black Leaf 40" tobacco preparation or kerosene emulsion and similar compounds, and at the latter period by lime-sulfur. If the rough bark is removed in winter and burned, very many of the pests will be destroyed. In some parts of the East the fruit is attacked by the pear midge, a minute fly whose maggots work in the very young fruit. Thorough cultivation will check this serious pest, but its complete control often involves the destruction of all the young fruit on the infested trees; the application of kainit to the soil in the second half of June (1,000 to 2,000 pounds to the acre on sandy soils in New Jersey) is said to kill the insect after it leaves the fruit to undergo its transformations. Repeated shallow tillage in early summer is a good protection.

The foliage and fruit of the pear are attacked by parasitic fungi, which cause the leaves to drop and the fruit to become scabby. These diseases are readily held in check by spraying with bordeaux mixture or lime-sulfur. More than fifty years ago the White Doyenne pear was the most popular variety for growing on the quince root, but because of the pear scab it passed away. It was supposed that the disease was due to uncongenial climate. Since the advent of the sprays, however, it has been found that the White Doyenne can be grown as well as ever. Flemish (Flemish Beauty) is also an example in point. Years ago it was one of the most popular standard varieties, but of late years it has been little grown because of the cracking of the fruit.

Pear-blight or fire-blight is the most serious disease of pear trees. It is an American disease. It is caused by a microbe which enters through the growing points

(flowers and tips of shoots) and thrives in soft or "succulent" parts. Gradually the micro-organism works down the stems, killing the tissues and causing the leaves to die. In the leaf-blight, which is a distinct disease, the leaves are more or less spotted and they fall; in the pear-blight, the leaves turn black and hang on the tree. The fire-blight also attacks apple trees,

2810. The Kieffer pear (pointed form), now one of the most important varieties. ($\times \frac{1}{4}$)

particularly in the Plains region. It is probably aboriginal on hawthorns and related plants. There is no perfect preventive of the disease. Some varieties seem to be relatively immune, as, for example, the Angouleme. It is now generally believed that trees are more subject to the disease when they are making excessive growth; therefore it is advised that tillage and the application of stimulating manures be moderate. As soon as the disease appears, cut out the affected parts, severing them some inches below the lowest point of visible attack. Do not allow blighted branches to remain on the tree over winter. Disinfect the wounds or stubs and the implements with bichloride of mercury or other antiseptic. Destroy hedgerows and thickets in which are other trees on which the blight is carried, as hawthorns, quinces, and diseased apple and pear trees. It is probable that there is a connection with insects in the spread of pear-blight.

Literature.

There are no recent American books on the pear. Two books have been written on this fruit: Thos. W. Fields' "Pear Culture," New York, 1858; P. T. Quinn's "Pear Culture for Profit," New York, 1869, new edition, 1883. There are bulletins from the United States Department of Agriculture and some of the state experiment stations. Many years ago the writer secured from the venerable T. T. Lyon (Vol. III, page 1585), an article, for publication, on the pear. This was published in the "Cyclopedia of American Horticulture." The Editor is glad again to place this article alongside the others in order to contrast the viewpoints of two generations. Mr. Lyon's article, which is excellent and cautious and characterized by beauty of style, is of the type that we no longer see. The person who is familiar with present-day points of view will discover that it lays the emphasis on formal presentation, propagation, pruning, varieties, whereas little or no attention is given to systems of tillage, pollination, spraying, and commercial methods. The methods in pear-culture, and the varieties, have probably changed less in the last fifteen to twenty-five years than those of any other standard fruit; as a whole, pear-culture is not extending to any marked degree; and the article that follows is still timely.

L. H. B.

The pear and its cultivation.

So far as cultivators generally are concerned, this fruit is less important than its near relative, the apple, for the reason that, while the two begin to ripen at nearly the same season, there are few, if any, desirable varieties of pears in season later than December (if we except a few austere ones, suitable only for culinary purposes), while apples are abundant for four or five months longer. Moreover, during its entire season, the pear is supplemented by the mass of luscious, though perishable, summer and autumn fruits. The liability of very many usually excellent varieties to be rendered indifferent in quality by unfavorable seasons, neglect or unsuitable soil, is also a serious detriment to the general popularity of this fruit. The liability to the loss of the trees by blight, beyond question detracts greatly from the value of the pear, especially for commercial purposes; while it also exerts a discouraging influence upon amateur planting. To the careful and discriminating amateur, as well as to the man of wealth, with a fondness for fruit-culture whether in person or by proxy, this fruit often assumes a prominence over any, if not all, others.

Extent of cultivation.

Doubtless, for reasons heretofore stated, pear trees are but sparingly planted by most persons. The fruit sent to market comes largely from the plantations of specialists who, with soils adapted to the purpose and the necessary knowledge of varieties, have undertaken the business as a commercial enterprise. In the climates of the seaboard, and, to a considerable extent, in the region of the Great Lakes, the pear is exceptionally successful; while away from the influence of large bodies of water, and especially in the prairie regions of the Mississippi Valley, from unsuitableness of climate or soil, or both combined, the trees are liable to be either killed or seriously injured in winter, and hence are short-lived and unprofitable.

Aspect.

Perhaps in no other important particular does the climate of eastern and central North America differ more widely from that of the pear-growing regions of Europe than in its liability to sudden and extreme variations of temperature. Owing to this climatic peculiarity, aspect becomes an important consideration in the selection of a location for a plantation of pear trees. As a means of avoiding the full influence of exposure to the rays of the sun, during the severer paroxysms of summer heat, while the trees are in actual growth, and also to mitigate the liability to alternate freezing and thawing in winter, a northerly or north-easterly slope is to be preferred; which, however, should be so gradual as not seriously to interfere with the convenience of cultivation. As we approach the northern limit of practicable pear-culture, however, a modification of this rule of selection may be found desirable, since, with the shorter growing season, a warmer exposure may prove necessary as a means of hastening maturity.

Soils.

While the pear tree will yield more or less satisfac-

2811. Section of the Kieffer pear, to show its ordinary form in the North.

tory results in a variety of soils, it is found to succeed most perfectly in a strong loam, of moderate depth, overlying a porous subsoil. Soils which are liable to be wet during any considerable portion of the growing season are unfit for this purpose, unless deeply and thoroughly underdrained; while even then they are quite liable not to prove fully satisfactory. A few

2812. A pear plantation.

varieties are found to be moderately successful on sandy soils, but for general planting such soils should be avoided.

Manures.

The liability of the pear tree, in this climate, to the attacks of blight is thought to be increased by excessive growth. It is, therefore, desirable that the annual growth be completed, and ripened at as early a date as practicable; and the more so since the liability to blight apparently exists only while growth is in actual progress. Stable and other nitrogenous manures should, for this reason, be applied in moderate quantities, in autumn, after the liability to excite renewed growth shall be past. Potash, lime, and phosphorus, which enter more or less largely into the composition of both tree and fruit, and which rarely exist in excess in the soil, may be profitably applied in either autumn or spring. Salt may also be profitably applied to the comparatively dry soils recommended for the pear, but with care not to apply in excess. One or even two quarts may be safely applied to each tree, before the commencement of growth in the spring, if well distributed upon the surface over a space of at least 6 or 8 feet in diameter, and left to be carried gradually into the soil by dew and rain. It is believed to possess little, if any, manurial value; but to act rather as a conservator of moisture, and probably also as a repellent of insects. Coarse mulch may be placed about the trees, covering the soil as far out as the roots extend, for the purpose of keeping the earth cool, and also to check evaporation from the soil; but this should not be done as a substitute for cultivation; and the soil beneath the mulch should be kept well pulverized.

Propagation.

(a) By seedlings: Seeds, when to be planted for the origination of new varieties, should be selected from well-grown and fully matured fruits, of such varieties as possess in a high degree the qualities sought to be reproduced or improved, since a variety in which a characteristic is strongly developed and persistently manifested is the more likely to transmit such peculiarity to its offspring. Seeds resulting from known or artificial cross-fertilization, and therefore of known and selected parentage on both sides, offer increased probability of valuable results. Seeds intended for the origination of new varieties should be planted very thinly in strong, rich, deeply prepared soil, in a single row, and covered with not more than an inch of earth, so that the young plants shall have ample space for development.

Seeds intended for the growing of stocks for nursery

purposes should be collected from varieties in which the seeds are plump and well developed, as well as from healthy, vigorous trees. American nurserymen obtain pear seeds mostly from Europe. Seeds intended for nursery stocks are usually planted in broad, shallow drills. In our American climate the foliage and unripened wood of seedling pears is very liable to be attacked

during midsummer by leaf-blight or mildew, which prematurely arrests their growth. For this reason European stocks are generally preferred by nurserymen. This attack of mildew may often be partially or wholly avoided by planting in virgin soil remote from other cultivated grounds. Pear seedlings form a very long tap-root during their first year, with few, if any, side-roots. For this reason they are taken up preferably in autumn, and the tap-roots shortened to 6 or 8 inches, when they may be replanted in nursery rows, and earthed up, or otherwise protected from heaving, or

other injury during winter; or, preferably, they may be heeled-in, in a frost-proof cellar, and planted in spring, to be budded during the ensuing summer or left to become more fully established for budding a year later.

Seedlings intended for fruiting are usually transplanted in rows, about 8 feet apart each way, with the expectation that many will be found worthless, and either removed or destroyed. Seedling pears usually require to be fruited several years before their characteristics become fully developed. This generally recognized fact may be taken as a warning that the occasional effort to hasten the puberty of a seedling by fruiting a cion from it upon a bearing tree of different variety cannot be trusted to indicate the ultimate character of the fruit of the yet incipient variety, since it is impossible to foresee to what extent such transfer may interfere with the occult formative processes through which its ultimate qualities would have been developed.

(b) By budding: Seedlings of one or two years' growth, intended for standard trees, are usually planted from 6 to 10 inches apart in the nursery row; for the reason that space, as well as cultivation, must be economized to correspond with prices, although it is impossible to grow trees of good form and properly branched of the size and age demanded by most planters when thus closely planted. Trees thus closely planted should

2813. Ladders used in picking pears.

be removed, or at least thinned, after having made one year's growth from the bud; while trees intended to be grown two or more years in the nursery row, and properly branched, should be given twice or even three times the space mentioned.

The budding of pear stocks may be done during July and August if they continue in a growing condition,

but they are liable to be attacked by mildew of the foliage, for which reason they must be closely watched, and should the malady prove troublesome the budding must be done as soon as properly matured buds can be obtained. Such stocks as, for any cause, were left unbudded at budding time, together with any in which buds shall have failed, may be grafted the following spring; but this, as well as any and all grafting of the pear, must be done very early, before the earliest movement of the sap in spring. In the spring, as soon as the swelling of the buds indicates that the germs are alive, the stocks are cut back to force them into growth. Often to insure the formation of straight, upright, symmetrical trees, careful nurserymen leave 3 or 4 inches of the stock above the insertion of the bud, to which the young shoots may be tied, if it shall fail otherwise to take an upright direction. Shoots may also be thus tied to prevent their being blown out, or otherwise injured by the wind. These stubs should be cut back to the bud when no longer needed for the purposes indicated. Such sprouts as spring from the stock in consequence of the cutting back must be removed from time to time to encourage the growth of the bud. This should be done while they are yet tender and succulent and can, therefore, be taken off without the use of a knife. This process must be repeated as they reappear, unless it is rendered unnecessary by the failure or loss of the bud.

Pruning.

Beyond that described under the head of budding, little pruning is required during the first season, except to pinch in such side shoots as threaten to rob the one intended to become the trunk of the future tree. Early in the spring of the second year, all lateral shoots must be wholly cut away, and since the pear tends strongly to renew its growth from the terminal buds of the previous year, the shoot intended to become the trunk of the future tree must be cut down to the point at which the top is to commence, when the branches to form the head will start from the buds nearest the top. The uppermost shoot must, if needful, be confined in an upright position to constitute the continuation of the trunk.

The habits of growth of varieties differ so widely that no inflexible rule can be laid down to determine the height at which the top of a pear tree should be commenced, unless it be that the heads of the more spreading varieties should be started higher than those of a more upright habit. The preferences of the larger number of purchasers have begotten among nurserymen the practice of forming the heads of all varieties at a height of 3 or 4 feet. This height is open to the objection that, while not seriously faulty in the case of such spreading varieties as Onondaga, Osband (Summer), or Flemish (Beauty), it is essentially unsuited to such very upright growers as Buffum, Sterling, Clapp (Favorite), and even Anjou. In this particular, as in various others, the practice of nurserymen, begotten by the preferences of the average of their customers, fails to adapt itself to the needs of the more intelligent and considerate orchardist, and to those of even smaller planters, who regard the health and productiveness of their trees as of higher importance than the possibly increased convenience of cultivation.

A proper system of primary branches, upon which to grow a permanent head, should be provided from the growth of the second season. Probably the most satisfactory provision for this purpose consists of a central shoot, with from three to five laterals diverging from the trunk at its base. A head should, in no case, be grown upon two shoots, forming a crotch, since this will be very liable to split and thus ruin the tree. A few varieties, of which Rostiezer is a notable example, have the habit of producing but few branches, and also of making successive annual growths, mainly from the terminal buds of the previous year, thus forming a too

open or straggling head. Such tendency is best overcome by cutting back the branches in spring, the effect being to increase their number, though at the expense of vigor.

After the primary branches have been developed, and the growth of the third year is in progress, comparatively little pruning will be found necessary beyond the occasional cutting away of a straggling or crossing branch, although there is a class of varieties, of which Summer Doyenne and Winter Nelis are types, which, especially when growing vigorously, incline to twist and

2814. Seckel, the standard of quality. ($\times \frac{1}{2}$)

straggle so awkwardly that the branches must frequently be tied in position to insure the formation of a satisfactory head.

Prior to the third or fourth year, all pruning must necessarily have for its object the direction and encouragement of wood-growth, for which purpose it is most effective when performed in late winter or early spring, while the trees are yet dormant.

The fact should not be forgotten that pruning, in proportion to its extent or severity, may be a tax upon the vigor and health of the tree, and, therefore, to be practised as sparingly as possible. Such necessity may be to a considerable extent avoided if the orchardist, with a well-defined ideal in mind of a tree such as he desires to produce, will, during the growing season, pass frequently through his plantation and pinch out, while yet small and succulent, all growths not needed for his purpose, at the same time "stopping" such of the reserved ones as may be too far outgrowing their fellows. With the efficient performance of this process while the framework of the top is being developed, very little pruning will remain to be done on the arrival of spring, while nearly the entire growth, which would otherwise have been pruned away in spring, will have been employed in developing the reserved branches.

While the cutting away of an occasional small branch may be done at almost any time, large branches should be removed only in case of actual necessity, and at a period early enough to permit the thorough drying and hardening of the cut surface prior to the movement of the sap in spring, as a means of preventing bleeding and consequent decay.

Summer pruning tends to check rather than encourage wood-growth, and since it acts to a greater or less extent as an obstruction to the circulation, it also tends,

as does the permanent bending of the branches and the hardening of the tissues, to hasten the formation of fruit-buds and the production of fruit.

The pear may be successfully grafted upon the white thorn, the mountain-ash, and the apple, and such grafts have occasionally proved more or less productive for a time, but in such cases the union between stock and cion is generally, if not always, imperfect; and such uncongenial combinations are therefore usually short-lived. The quince is the only dissimilar stock upon which the pear is extensively grown. Quince stocks for this purpose are largely imported from France. The Angers quince is generally preferred for this purpose. These stocks are usually planted in nursery rows at the age of two years, to be budded during the following summer, in the same manner as pear stocks. When intended for dwarf trees, nurserymen usually cut them back after one year's growth from the bud to the nearly uniform height of 18 inches, although with the more

of which Bosc may be named as a prominent case, are obstinately unsuccessful upon the quince, and even when double-worked upon a dwarf of a congenial variety, their success appears to be by no means assured.

Dwarf trees trained as hereinbefore specified are commonly known as half-standards. Other and more elaborate forms are known as pyramids, cordons, and the like, descriptions of which are not deemed necessary here.

Choice of trees.

Aside from the selection of the location for an orchard, the first important particular is the selection of the trees, leaving the choice of varieties for subsequent consideration. Trees of one year's growth from the bud are to be preferred for the following reasons: (1) Fewer roots need be injured or lost in the process of lifting and replanting, for which reason the tree may be expected the more promptly to recover from the shock of removal. (2) The single season's growth may be cut back and the top commenced to suit the preferences of the planter. (3) The top will present little or no obstacle to the force of the wind until the roots shall have gained such hold upon the soil that there will remain little liability to displacement from this cause. (4) The risk of failure from removal is greatly diminished, while the more prompt recovery and increased rate of growth of the trees in the more open orchard rows may be expected to compensate fully for one or two years more of growth in crowded nursery rows. (5) Something will also be saved in the cost of the trees and in the expense of transportation, as well as in the labor of planting.

If older or high-branched trees are not objected to, it will usually be found that they are but imperfectly branched from having been grown in crowded rows.

Preparation of the soil.

When the late John A. Warder was asked how large the holes should be dug for planting orchard trees, he replied, "Of the full size of the orchard;" and it may also be remarked that when the ground for an orchard has been well tilled and fertilized to a depth at least equal to that at which trees are to be planted, there is no longer occasion for holes larger than shall be necessary to receive the roots in their proper position. If the subsoil be not freely pervious to water, the ground must be deeply and thoroughly underdrained, and in no case should the hole in which a tree is to be planted be sunk into a subsoil so impervious as to retain water beneath or about its roots. If such retentive subsoil occurs too near the surface and is not considered suitable to be mixed with the surface soil, it should be thoroughly disintegrated to the requisite depth by means of a subsoil plow or other equivalent device. In all nearly level retentive soils, it will be found advantageous to "back-furrow" a land along the line of each row in the direction of the surface drainage, so that when the trees have been planted the drainage will be away from them.

Laying out, staking, and planting.

The most economical mode of laying out and planting an orchard, so far as space is concerned, is doubtless that commonly, but erroneously, designated as quincunx, and more correctly as hexagonal; but whether planted thus, or in rectangles, the work may be most rapidly and accurately done by planting a stake where each tree is to stand, and using what is known as a planting-board, consisting of a strip of board 6 or 7 feet long, with a hole for a stake near each end, and a notch or slot intermediate and in line between them to receive the stake, and to support the tree while the earth is being carefully filled in, under, among, and above its roots.

The following are good general rules to be observed

2815. Anjou, one of the popular late autumn and early winter pears. ($\times \frac{1}{2}$)

upright-growing varieties it is by many deemed preferable to branch them even 6 or 8 inches lower. Aside from the height at which they should be branched, the pruning and management should be identical with that prescribed for standards, with the important exception that when planted out for fruiting the junction between the quince and the pear should be 3 or 4 inches below the surface to encourage the formation of roots from the pear. Trees thus planted will begin to bear while yet growing solely from the quince stock, and will continue to produce fruit after rooting from the pear, thus affording the early fruiting of the dwarf, as well as the permanency of the standard.

Not more than a specimen or two should be permitted to grow upon a dwarf the first and second years after planting. Such trees, if left to fruit freely, will almost certainly be ruined from overbearing before they are fully established. Many varieties when grown as dwarfs can never be safely allowed to mature more than a small portion of the fruit which they will naturally set.

While several varieties are found to be especially successful when grown upon the quince, most others prove only moderately so, requiring careful and expert management to insure satisfactory results. A few others,

in the digging, handling, preparing, and planting of trees:

1. In digging trees, aim to secure as many of the main fibrous roots as possible.

2. Expose the roots as little as possible to the drying influence of sun and wind.

3. Prepare the roots for planting by cutting away the bruised and broken portions.

4. If the roots have been essentially shortened in lifting, cut away the superfluous branches and also cut back such as are to remain till a proper balance of root and top is secured.

5. In heavy retentive soil, plant the tree very little if any deeper than it stood in the nursery, and, in addition, raise a slight mound about the trunk to avoid the occurrence of standing water at that point.

6. In strong but dry soil, a tree may be planted an inch or two deeper than it stood in the nursery.

7. In light sand, with dry subsoil, a tree should be planted 3 or even 4 inches deeper than it stood in the nursery.

8. Dig the hole in which a tree is to be planted deep enough to receive 2 or 3 inches of fine soil, before putting the tree in place, making it large enough to allow the roots to be spread out in their natural position.

9. See that good, friable surface soil is well filled in beneath, among, and over the roots.

10. Should the soil be dry, with no immediate prospect of rain, it will be well after nearly filling the hole with earth, to apply a pail of water, and, after it shall have settled away, to fill up the hole with earth and tramp it down firmly. Staking will rarely be found necessary, except, possibly, in the case of trees old enough to have been already branched, but such stake must be watched and the tree protected against injury by rubbing against it.

Subsequent cultivation.

(a) Newly planted trees: Ground occupied by young trees must be kept well cultivated during the spring and

after planting, in case of hot dry weather during the growing season, mulch may be applied to check evaporation from the soil and to keep it cool, but it should not be permitted to take the place of cultivation. The soil should be well pulverized before applying it.

(c) Manuring: As stated previously, manures should be applied sparingly but regularly, preferably in late autumn, and should be plowed under, or otherwise mixed with the soil at that time or in the early spring, as a means of promoting early growth and the thorough ripening of the wood in advance of severe cold. Thorough maturing of the

2817. Stump of the Seckel pear tree. 1908.

wood should also be assisted, as already said, by ceasing cultivation the early part of August.

Gathering and ripening the fruit.

All selected pears, whether intended for the market or for use at home, should be carefully hand-picked.

(a) Gathering summer and autumn pears: With very few exceptions all pears acquire a higher quality if gathered before they are fully ripe. The generally accepted rule is to gather the crop when an occasionally full-grown wormy specimen is ripe, or when there is a perceptible change in the color of the maturer specimens, or when the stem parts readily from the branch if the fruit is slightly lifted.

(b) Ripening summer and winter pears: When gathered, the fruit should be placed in a cool room devoted to the purpose, and spread upon shelves, or in lack of a suitable room they may be placed in shallow boxes or drawers, where in due time they will acquire their full color and flavor. Since this fruit parts with moisture quite freely, it, and especially the later ripening varieties, should be protected from a drying atmosphere, particularly from drafts of air, which will cause the fruit to shrivel and become tough and leathery. It is also true of at least very many varieties that even if blown off or gathered when but two-thirds grown, the fruit if put away as already described will usually acquire a satisfactory quality. Fruits thus gathered and ripened are found to have less tendency to decay rapidly at the core.

(c) Gathering and ripening of winter dessert pears: These should remain upon the tree as long as practicable without danger from frost. When gathered, they should be placed in a cool frost-proof room, and it will be well also to wrap each separately in soft paper. Some varieties are found to ripen perfectly without further attention, but the quality of most kinds will be much improved if they are brought into a temperature of 60° or 70° a fortnight before their usual season of maturity.

(d) Winter cooking pears: These should be gathered and put away in close packages in a cool, frost-proof room, in the same manner as russet apples, like which they will shrivel, and become tough and leathery if left exposed to the air. They may remain in this condition until needed for use.

Packing and marketing.

In America, pears are generally packed for market directly from the tree, without awaiting the process of ripening. Barrels are largely used as packages, although this fruit is frequently put up in half-barrels and sometimes in bushel, peck, and even in half-peck baskets.

2816. The Seckel pear tree as it stood in 1880.

early summer. If hoed crops are planted, larger quantities of manure will be required; but, in either case, cultivation should cease as early as the beginning of August in order to hasten the ripening of the young wood. This process should be continued during at least five or six years, after which green crops may be grown and plowed under as a means, in part, of maintaining the fertility of the soil.

(b) Mulching: Especially during the first few years

American growers rarely ripen their fruit before marketing it. This, if done at all, is more generally accomplished by the dealer, doubtless with decided profit, since in the larger cities fully \$50 have been known to be paid for a single barrel of selected fruit, and yet the same fruit ripened and offered in quantities to suit customers has been sold at two or three times the original cost. The marketing of unripened pears is obviously unprofitable so far as the producer is concerned.

In Europe, the choicest fruits are carefully selected and house-ripened. When approaching their best condition the fruits are separately wrapped in soft paper, and are then put up in packages of perhaps one or two dozens, and sent so as to appear upon the market when in the best possible condition. Such fruits command prices quite in excess of what they would have realized had they been offered in an immature condition.

Varieties.

Since the popular and desirable varieties of pears may be found fully described in standard pomological works, such descriptions here are not deemed necessary. Among the very numerous varieties of pears described in such works there are doubtless many possessing high quality and other valuable characteristics, which, for some unexplained reason, have failed to attract the attention of growers.

Since varieties vary in their season of ripening with change of latitude, and often, to some extent, with change of location, even in the same latitude, the designation of such season becomes a matter of more or less difficulty. In the following lists the season given will be approximately that between parallels 42 and 43 of north latitude.

(a) Amateur pears: It is as true of the pear as of most other species of fruits that very many varieties are of small size, unattractive appearance, or of such delicate texture when ripe as to disqualify them for the market, although they may possess, in an eminent degree, the peculiar characteristics which render them desirable, and to persons of cultivated taste, indispensable for the supply of the family. Such are termed amateur pears.

The following is a list of a few of the most popular of these, arranged approximately in the order of maturity:

Name.	Season.*	Remarks.
Madeleine.....	m. e. July.....	Earliest good pear.
Summer Doyenne.....	e. July.....	
Bloodgood.....	e. July. m. Aug.	
Giffard.....	m. Aug.....	Excellent, but very per-
Dearborn.....	m. e. Aug.....	ishable.
Rostiezer.....	m. Aug. m. Sept.	
Elizabeth.....	e. Aug.....	
Brandywine.....	e. Aug. b. Sept.	
Tyson.....	e. Aug. b. Sept.....	A tardy bearer.
Stevens (Genesee).....	b. Sept.....	Rots soon at the core.
Clapp.....	b. m. Sept.....	Rots soon at the core.
Washington.....	m. Sept.....	
(Belle) Lucrative.....	m. e. Sept.....	
Bosc.....	e. Sept. Oct.....	
White Doyenne.....	e. Sept. Nov.....	Liable to crack badly.
Seckel.....	Oct.....	
Sarah.....	Oct.....	
Anjou.....	Oct. Nov.....	
Gray Doyenne.....	m. Oct. Nov.....	
Reeder.....	Nov.....	
Heyst (Emile d'Heyst).....	Nov. Dec.....	
Mount Vernon.....	Nov. Dec.....	
Dana Hovey.....	Nov. Jan.....	
Langelier.....	Nov. Feb.....	
Germain.....	Nov. March.....	
Lawrence.....	Dec.....	
Winter Nelis.....	Dec. Jan.....	
Easter.....	Jan. March.....	

*e, early; m, middle; b, beginning.

(b) Culinary pears: Very few dessert pears are found to be satisfactory for culinary uses, since they too generally lose at least a portion of their flavor and aroma in the process of cooking. There are, however, several varieties of high, austere character which prove adapted to this purpose, among which are the following:

Name.	Season.	Remarks.
Vicar.....	Nov. Jan.....	Occasionally good
(Black) Worcester.....	Nov. Feb.....	Enough for dessert.
Catillac.....	Nov. March.....	
Pound.....	Dec. Feb.....	

(c) Market pears: The markets demand varieties of attractive appearance, of at least medium size and of fine texture. To the grower, productiveness and vigor of tree are also of primary importance. If possessing

2818. Packing pears in boxes.

the foregoing characteristics, a variety may prove at least temporarily popular, even though of comparatively low quality. The following varieties, some of which may also be found in the amateur list, are all more or less popular as market fruits:

Name.	Season.	Remarks.
Tyson.....	e. Aug. b. Sept.....	Excellent, but a tardy bearer.
Sterling.....	e. Aug. m. Sept.....	Productive, and exceedingly beautiful.
Clapp.....	b. m. Sept.....	Rots soon at the core.
Bartlett.....	b. e. Sept.....	Leading market pear.
(Souvenir du) Congress.....	b. e. Sept.....	Sometimes very large.
Buffum.....	m. Sept.....	Variable in quality.
Howell.....	m. Sept. Oct.....	
Flemish (Beauty).....	m. e. Sept.....	Rots soon at the core.
Bosc.....	e. Sept. Oct.....	Excellent for all purposes.
Boussock.....	e. Sept. Oct.....	
Louis Bonne.....	e. Sept. Oct.....	Grown only as a dwarf.
Onondaga.....	e. Sept. Nov.....	
Superfin.....	Oct.....	
Sheldon.....	Oct.....	Is russeted and dull in color.
Rutter.....	Oct. Nov.....	
Anjou.....	Oct. Nov.....	
Kieffer.....	Oct. Nov.....	Not valuable north of 43°.
LeConte.....	Oct. Nov.....	Succeeds best at the extreme South.
Angouleme.....	Oct. Nov.....	Grown only on quince stocks.
Diel.....	Oct. Dec.....	
Claireau.....	Oct. Jan.....	
Columbia.....	Nov. Jan.....	
McLaughlin.....	Nov. Jan.....	
Lawrence.....	Dec.....	
Malines.....	Jan. Feb.....	

Relative desirableness of dwarfs.

There are a few varieties, among which Louise Bonne and Angouleme may be especially mentioned, which on free (pear) stocks are either tardy bearers or require to be fruited several years before developing their ultimate qualities, but which succeed unusually well upon the quince. These, especially the Angouleme, are valued as market varieties when grown as dwarfs.

Angouleme, and perhaps some other varieties as dwarfs, occasionally bloom so profusely as apparently to prove unable to develop the fruit, which in consequence proves abortive. The natural and obvious remedy in such case is disbudding, or its equivalent, cutting back the fruit-bearing shoots before growth is commenced.

The fact that very many varieties are not permanently successful when grown upon the quince is doubtless partially, if not in many cases even wholly,

due to their increased tendency to early and excessive productiveness when grown upon that stock, which, owing to the very common unwillingness of the grower to remove the excess of fruit, is allowed to consume the material needed for wood-growth, and thus to occasion exhaustion before the tree has gained a thorough hold upon the soil.

If, with any variety capable of forming a satisfactory union with the quince, and with the tree planted in the manner heretofore described, the entire crop of bloom or incipient fruit of the first one, two, or even three years (dependent upon the vigor of the tree) were removed, and if subsequent crops were carefully and thoroughly thinned, it is at least highly probable that permanent health and longevity would prove nearly or quite as general with dwarfs as with standards, thus permitting the more extensive growth of the pear in greater variety in small or amateur plantations and in limited grounds than is practicable with the use of standards.

T. T. LYON.

The pear in the South.

The following table from the Thirteenth Census shows the status of the pear industry in thirteen southern states, 1910 (crop data 1909):

State.	Number of trees.	Production in bushels.
Alabama.....	142,300	100,041
Arkansas.....	221,764	37,547
Florida.....	110,709	98,223
Georgia.....	262,982	149,667
Kentucky.....	337,355	251,536
Louisiana.....	57,630	35,554
Mississippi.....	118,536	101,288
North Carolina.....	243,367	84,019
Oklahoma.....	235	22
South Carolina.....	105,251	65,680
Tennessee.....	233,407	83,557
Texas.....	558,478	110,967
Virginia.....	457,177	74,486
Total.....	2,849,191	1,192,587

Throughout the whole South the average production of pears to the tree is less than one-half bushel. Virginia and Kentucky have many pear trees in comparison with the other southern states, but should hardly be considered with the remainder of the South, as their pears are produced mainly on the northern borders of the states. Texas, on account of its area, has more pear trees than any other southern state; and El Paso County, the most western county, produces over 22,000 bushels. Conditions existing in this region are not at all comparable with the other pear sections in the South.

It can hardly be said that pears are well adapted to southern conditions, although in certain sections, particularly in the mountains, it is possible to produce fruits of good quality; but on account of the blight the industry has never attained importance. At one time, the late P. J. Berckmans, of Augusta, Georgia, had 600 different pears under test in his nursery, 500 of them being named varieties. Berckmans says that of the 600, those of any worth in the South would not exceed twelve in number, and that the great commercial varieties were the LeConte, Garber, and Kieffer, although Bulletin No. 126 of the Bureau of Plant Industry shows seventy-seven varieties of pears that have originated in the thirteen southern states.

The history of the southern pear industry begins with the introduction of the LeConte into Thomasville, Georgia, in the early seventies of the last century by L. L. Varnadoe. The original cutting carried into Thomas County came from Liberty County, Georgia. This pear was planted extensively around Thomasville, being taken from there into northern Florida, southern Alabama, Mississippi, Louisiana, and Texas. The propagation was mainly by cuttings, and in the early

days of the industry \$1 apiece was often paid for trees. At one time it was conservatively stated that there were at least 200,000 trees in Thomas County. Great prices were received for the product, the growers in those days netting from \$3 to \$7 a barrel. There are reports from H. H. Sanford, one of the early growers of this fruit, of LeConte trees producing thirty bushels or more. The growing of this pear, like many other horticultural industries in the South, was along extensive rather than intensive lines. The growers thought that they did not need to till or to fertilize their lands and that they could plant these wonderful trees and reap a harvest of dollars, and for a time it seemed as if this were so; then the blight appeared. The "die-back," as it was originally called, began, and between 1890 and 1895 the industry was in a fair way to succumb. No systematic efforts were made to combat this disease, except by introduction of the Kieffer, which was considered at that time resistant, and which was largely planted in the pear sections of the South.

Because of the blight and lack of care, with no systematized methods of marketing, the pear industry of the southern states fell to a low ebb. For the past several years no commercial orchards have been set, and a great number of the trees that were planted in this early period are either dead or cut down; therefore the production of the hybrid pears in the South is not only at a standstill, but is at this time declining.

The management of these orchards, even while the industry was at its height, was very crude. It is reported on good authority that 95 per cent of the pear plantings in the southern pear sections were most seriously neglected. Some orchards were cropped, to the detriment of the land; others so badly neglected that young pine trees contended with the pears for space; consequently the fruits were not of the best quality. The growers who followed approved methods of tillage and fertilizing received a serious set-back when the blight appeared, as these plantings seemed to be more susceptible to this disease. In time a balance was

2819. Box of fancy pears; each fruit wrapped in paper.

reached, and it is now considered good practice to run the orchards in sod and every third year to give a light plowing, the application of fertilizers being determined by the growth of the tree. Spraying was little practised in the older orchards. The growers who are still producing pears now find the use of a spray-pump advisable. Harvesting during the height of the pear industry in south Georgia was aptly described by the Thomasville "Times Enterprise." "The annual slaughter of the LeConte pears has commenced. The trees are full of little gamins, picking a few, flailing some and shaking off the remainder. All—good, bad, and bruised—are dumped into barrels and rushed to market." It is unfortunately true that many of these fruits were gathered in this way. There were growers who hand-picked their product, carefully packing it into ventilated barrels. These, however, were the smaller

number. There is an instance on record of a gentleman having sold three hundred and odd dollars' worth of pears from a small orchard, on which he had expended \$5 since the last harvest. Most of the pears were shipped in barrels, though some were shipped in bulk. The distribution is still poor, and for the past few years

2820. Angouleme pear, the most popular variety for growing on quince roots.

the profits from the remaining trees have not been sufficient to warrant further planting.

At present, the South as a whole cannot be considered as a pear-producing section. There are still quite a number of pear trees around the homes. These are rapidly disappearing, due to the blight and the lack of care. The old orchards along the Atlantic and the Gulf are rapidly dying with blight. The hybrid pears, LeConte, Kieffer, and Garber, do remarkably well in this part of the country; but the pear industry will never thrive as it did once until there is a systematic fight made upon the blight. Besides this disease, the pears are subject to bitter-rot, brown-rot and crown-gall, as well as the codlin-moth and the San José scale; but of course these insects and diseases can be easily controlled by spraying.

In the catalogue of fruits appended to the Proceedings of the Thirty-Ninth Annual Session of the Georgia State Horticultural Society is to be found this remark concerning pears: "Owing to the prevalence of the pear blight, the commercial production of pears is an uncertain and hazardous industry. Until it is demonstrated that pear-blight can be successfully controlled, it is useless to recommend the planting of pears in commercial quantities. So far as is known, the Kieffer pear is the most resistant to the pear-blight of the commercial varieties." This report of the Georgia State Horticultural Society can be taken as a general recommendation for practically all of the South, except for particularly isolated and special places.

T. H. McHATTON.

The pear in California.

Visitors at the old California missions during the early part of the last century noted many thrifty seedling pear trees in the mission gardens. Many of these trees survived the neglect which came upon the mission properties after their secularization, and were in thrifty growth and bearing at the time of the American occupation. The first pears sold in San Francisco and in the mines in 1849-1850 were gathered from the old mission trees, and some of these old trees grafted over gave the first California product of the European and American varieties of more than half a century ago. From this beginning the growth of pears increased until the commercial product of 1914 included the following: 2,725 carloads sent overland to eastern and foreign markets (about the same as for the five years preceding); 2,000,000 pounds dried pears shipped to the same destination (a decreasing product because of the increasing demand for shipping fresh and canning);

805,740 cases of canned pears, mostly Bartletts—a product which is rapidly increasing. There are about 2,000,000 pear trees in California orchards. The decade 1905-1915 was a sensational period in California pear-growing because of the appearance of the pear-blight about 1902. It made such rapid progress that in 1904 practically all the pear trees in one district were seriously attacked and largely destroyed. Control measures were provided by state appropriation in 1905 and continued several years, and it was demonstrated that the disease can be held in check and profitability of trees continued by cutting out all blighted parts from twig to root—disinfecting between cuts all tools used in the work. This demonstration, coupled with an apparent lessening of the virulence of the disease, restored confidence among growers and resulted in largely increased new planting in 1914-1915.

It is a most interesting fact that a single variety furnishes a very great part, perhaps even as much as four-fifths, of the pear products of the state, and that is the Bartlett. Whatever it may lack in high quality is more than compensated for by its commercial serviceability. It is handsome and of good size, endures long carriage, cans well and dries well, and is of sufficiently good quality to please consumers: in fact the California-grown Bartlett is said to be better than the same variety grown in the Atlantic states and in the west of Europe. This is not, however, the chief reason why the Bartlett so largely preponderates in California. The ruling condition is found in the fact that owing to the marked differences in localities not widely distant and yet differing in elevation, in exposure to coast influences and away from them, and other local causes, the Bartlett has a very long ripening season, and valley, coast, and mountain Bartletts follow each other through nearly three months and thus make succession of different varieties during this period unnecessary. There is, however, at present a greater disposition than heretofore to extend the season by growing other varieties, but they are selected for resemblance to the Bartlett type. Clapp Favorite is sold as an "Early Bartlett," and a Winter Bartlett, an Oregon seedling, has been planted to carry the same style of pear as late as possible. Still some progress is being made in extending the California list of popular pears and some of local and of distant origin will probably achieve prominence, especially in the shipments to distant markets.

California pears are grown on pear-seedling roots (especially of the Japanese pear because of less liability to blight in the root), very little recourse being had to rooted cuttings or to dwarfing stocks. A dwarf pear tree is almost a curiosity. The heavier loams and even clays are sometimes planted with pear trees, not because they are best for pears but because other fruits do

2821. Dwarf pear trees forty-five years old, in a New York orchard.

worse than they. To plant fully the area intended for fruit, pears will go on the intrusions of heavy or too moist soils, while the freer soil will be given to other fruits. Still the chief product of pears is from the best loams California affords, and the profits from the tree warrant the use of such land. Pear trees are regularly pruned to a low vase form, but seldom opened in the center, the interior being used for bearing wood, and foliage enough retained partially to shade the fruit. The fruit is thinned to favor size and to relieve the tree from overbearing. Irrigation is employed in some parts of the state. The varieties chiefly grown are the following: Bartlett, Winter Nelis, Easter, Comice, Glout Morceau, Hardy, P. Barry (a California seedling), Seckel, Lawson (Comet), Winter Bartlett, Wilder.

PEAT is a kind of soil formed by the partial decay of plants in the swamps of the temperate zone. It is a standard potting material in greenhouse work for certain classes of plants, as ferns, orchids, heaths, rhododendrons, and other ericaceous plants, woody plants from Australia and the Cape of Good Hope, and many other choice and difficult subjects. American gardeners complain that they are handicapped in growing such plants because American peat is poorer than European, the lack of fiber being chiefly deplored, but it is probable that just as good peat is to be found in this country.

The peat-bogs of England are often 5 or 6 feet deep, and some of the Irish ones are said to be as deep as 40 feet. They have been forming ever since the glacial period, but are now on the decline, owing largely to natural causes. Peat-bogs consist of the remains of many kinds of aquatic and marsh plants, but chiefly sphagnum (which see). This moss grows upward and decays partially below, complete decay being prevented by the antiseptic organic acids formed in the process. Near the top the peat is brown, fibrous, light and porous: lower down it tends to be black, heavy, dense and without visible indication of its vegetable origin. The ash varies from 1 or 2 per cent in newly formed peat to 10, 20, or even 30 per cent in the older peat. Peat is commonly used for fuel by the Irish peasantry, but almost never in America, where other and better fuel is plentiful. In greenhouse work peat is valued more for its porous moisture-holding properties than for its plant-food. If dried, it may be used as an absorbent for liquid manure, "not so much for its inherent value," says Roberts (in his "Fertility of the Land"), "as for conserving the nitrogen in the manure, and for improving the condition of the stables." For this reason the half-decayed peat is extensively used in Europe, under the name of moss litter, as a bedding in stables, and later of course applied to the land.

The transformation of peat-bogs into arable land is rarely a pressing problem in America. It is usually too costly for a new country. The notion, however, is very common that peat lands are extraordinarily rich in plant-food. Nevertheless, according to Roberts, swamp muck and peat are not richer in plant-food than the good soils, with the exception of the nitrogen in the peat, which, however, is far less available than it is in good soils. (American peat contains about .67 per cent nitrogen, .21 per cent phosphoric acid, and .13 per cent potash.) Peat lands differ from good arable soil in being cold, sour, and too wet. To reclaim them, one must drain off the superfluous water and apply lime

freely to destroy the harmful organic acids. Sometimes sand or clay may be added to improve the texture of such soils. It takes time to reclaim peat lands. Thoroughly decayed peat intermingled with wet soils is muck. See the article on *Muckland-Gardening*, Vol. IV, page 2072.

WILHELM MILLER.

PECAN, *Carya Pecan*, Engler and Graeb. (*Carya olivaeformis*, Nutt. *Hicoria Pecan*, Brit.). Plate LXXXV, Vol. IV. Of the nut-trees native to North America, the pecan unquestionably ranks first in economic importance. This is true both because of the quantity and value of the wild crop and because of its cultural promise. The acceptability of the quality of the kernel and the relative thinness of shell and ease of cracking in contrast with the other hickories and the native walnuts, have since an early day continued to win favor among consumers, so that the wild crop of Louisiana and Texas long ago assumed commercial importance and for at least thirty years has, in the

2822. Foliage and flowers of pecan. The hanging parts are the staminate catkins. A pistillate catkin is below P. Details are at a (staminate flowers) and at b (a pistillate flower).

latter state, been systematically harvested and distributed in carload shipments to northern markets.

The relatively wide climatic range of the species and the extent of variation in form, size, and quality of nut have stimulated effort to develop methods of nursery propagation in widely separated localities. This has resulted in a larger and more widely scattered development of commercial nursery propagation of the pecan than of any other nut-tree.

Under favorable conditions of growth, the pecan tree attains very large size, trunk diameters of 4 to 6 feet being not infrequent, with heights ranging from 100 to 175 feet and tops spreading 60 to 70 feet. Some of the largest trees reported were in the Wabash Valley, near the northern limit of natural distribution. A tree having a girth of 18 feet 3 inches breast high from the ground, with an estimated height of 130 feet and a spread of 125 feet, is recorded by Reed in Ascension Parish, Louisiana. One having a girth of 19 feet 6 inches with an estimated height of 150 feet and spread of 100 feet, is recorded in Nachitoches Parish, Louisiana. A still larger tree near Webbers Falls, Oklahoma, has the following dimensions: Girth 23 feet 9 inches at 3 feet from ground; estimated height 180 feet.

The pecan is one of the hickories which comprise an American group of great interest. The trees are monoecious; that is, the male and female (staminate and pistillate) are separate on the same plant. (Fig. 2822; adapted from Bulletin No. 251, Bureau of Plant Industry.) The staminate or pollen-bearing flowers are in slender hanging catkins, and the pistillate or fruit-bearing flowers are in small erect or stiff clusters (Fig. 823, page 676). Several of the staminate or male flowers are shown separately at *a*, Fig. 2822, and one of the pistillate or female flowers at *b*.

Natural and cultural range.

The species is native in river-bottoms and lowlands of the Mississippi River and its tributaries as far north as Davenport, Iowa; Covington, Kentucky; Terre Haute, Indiana; and the vicinity of Kansas City, Missouri. It is also found throughout most of the river-valleys of Texas and the adjacent parts of Mexico. It does not appear to have been found native at any point in close proximity to the Gulf of Mexico. It thus occurred wild in considerable regions of Texas,

2823. Pecan tree, the Centennial, St. James Parish, Louisiana. Grafted about 1847.

Oklahoma, Louisiana, Mississippi, Alabama, Arkansas, Missouri, Kansas, Tennessee, Kentucky, Indiana, and Illinois, and small areas in southeastern Nebraska and southeastern Iowa. The species was scatteringly introduced throughout the southeastern states from Florida northward to Virginia at an early date, so that trees of considerable age are found at many points in them. The earliest efforts at commercial planting appear to have been made in Louisiana, Mississippi, and Texas, but some of the greatest activity in this direction in recent years has been outside of the native habitat, in Georgia, Florida, and South Carolina, and considerable plantings have been made also in North Carolina, Virginia, Maryland, and some on the Pacific Coast in California and Oregon.

Commercial importance.

As an article of commerce, the pecan did not receive much recognition until after the Civil War; but, increasingly large shipments of wild nuts moved northward from Louisiana and Texas from 1870 to 1890 at prices which encouraged farmers and ranchers to harvest them systematically, though not to engage in orchard planting. Early in the nineties, as the result of the marketing in New Orleans of the product of a few

individual trees yielding nuts of large size and thin shells, demand developed for such nuts at much higher prices, frequently bringing 40 to 75 cents and in some cases as high as \$1.50 to \$2.50 a pound. This stimulated interest in the planting of seedling orchards grown from the nuts of these high-priced varieties, with the result that many thousands of such trees, mostly dating to the decade 1890-1899, are now found in the Gulf and South Atlantic states. While these seedling orchards contain many productive trees yielding nuts of desirable quality, few of them have proved profitable, largely because of the wide variation in precocity, productiveness, and disease-resistance of the trees, and in the size, cracking quality, and other features of the nuts, so that a large part of the present production still consists of wild nuts. Reed estimated in 1912 ("The Pecan," Bureau of Plant Industry Bulletin No. 251) that the annual wild crop of pecans in Texas during the preceding six or eight years had varied from 3,645,000 to 17,820,000 pounds, the crop of that state being considered approximately three-fifths of the entire product. The census of 1910 reported the crop of 1909 as 9,890,769 pounds, valued at \$971,596.

While no accurate statistics regarding later production are available, the product of the orchards of named varieties planted prior to 1905 is now gradually coming to market, and may be expected to appear in rapidly increasing quantity in the future, to offset the gradually declining production of wild nuts resulting from the destruction of trees as the fertile river-bottom lands on which they stand have been brought under cultivation in farm crops.

The gradual development of power nut-cracking machinery, mainly accomplished since 1900, has resulted in a greatly increased demand for pecan meats from confectioners, which promises to keep pace with production for many years to come. These devices greatly lessen the labor cost of cracking, and render possible much more varied use of the nut.

Climatic and soil requirements.

Much confusion of thought with regard to the climatic range of the pecan has resulted from failure to recognize the difference in cold endurance of wild trees of the species in different parts of its native range. Rather early in the period of pecan exploitation, which began about 1885-1890, nuts and young trees of the large varieties conspicuous in the exhibits and advertising matter of that time were planted at many points in the northern states. These rather promptly succumbed to the winter temperatures of the North, very few surviving north of the Potomac, Ohio, and Missouri rivers. More recently, trees well worthy of propagation because of the good size and excellent quality of their nuts have been found in the surviving wild groves of the Ohio and Wabash valley bottoms in Indiana, Illinois, and Kentucky, which give promise of enduring the winters considerably farther north, and which are now in process of experimental introduction. On suitable soils it now appears probable that among these varieties of northern origin may be found sorts fairly well adapted to most of the eastern United States.

Though practically restricted in its native distribution to the low-lying moist sandy loams of the river- and creek-bottoms, gradually accumulated experience has demonstrated the suitability under cultivation of a wide range of soils. The essentials are good depth and fertility, adequate drainage, and freedom from drought. Shallow soils underlaid with hardpan or other impervious strata and loose droughty sands are unsuitable, as are mucks and peats. Occasional overflow, as experienced on creek- and river-bottom lands, is beneficial, but the pecan is about as sensitive to a water-logged soil condition as most orchard trees.

While the orchards thus far planted are too young to determine with accuracy the area of profitable com-

mercial planting will, from present indications, be south of Pennsylvania and Iowa with some probability of success under irrigation in the Southwest and in the great valley of California.

Propagation and top-working.

Few of the earlier efforts to perpetuate trees bearing superior nuts by budding and grafting were successful, the methods commonly practised with fruit-trees in the Gulf States not proving effective with the pecan. Because of this, most of the plantings prior to 1900 were of seedling trees grown from selected parents, even where orchards as large as 500 acres were involved.

Occasionally skilful propagators succeeded in securing fair stands with crown-, trunk- and top-grafting, however, and some by annular-, patch- and chip-budding, so that by 1895 there were a number of

2824. Top-budded pecan. Four years after the operation.

budded and grafted trees of several choice varieties growing in Louisiana, Mississippi, and Texas and a few nurseries offering such trees for sale.

The earliest successful grafting was by Antoine, a slave gardener, on Oak Alley Plantation, St. James Parish, Louisiana, who, under the instruction of his owner, the late Telesphore J. Roman, in 1846 or 1847 succeeded in trunk-grafting sixteen trees of the variety later named the Centennial (Fig. 2823). Somewhat later he propagated 110 more trees of the same variety, so that 126 grafted trees of this variety were growing on that plantation at the end of the Civil War. About 1877, the late Emil Bourgeois, of Central, Louisiana, successfully top-grafted the variety now known as the Van Deman upon his Rapidan Plantation in the same parish, while in 1882 the Rome and Frottscher, as well as Centennial, were propagated by Wm. Nelson in the nursery of the late Richard Frottscher at New Orleans from the original trees in St. James and Iberia parishes. In 1886, the variety now known as Stuart

was successfully budded by the late A. G. Delmas on his place at Pascagoula, Mississippi, from the original tree of that sort on the Castanera place near by.

Successful top-working of wild trees was accomplished by E. E. Risien, of San Saba, Texas, about 1889. He

transformed a number of such trees by cutting back heavily in late winter with a cross-cut saw, practically beheading trees of diameters up to 12 to 15 inches at points 20 to 30 feet from the ground. An abundant growth of strong shoots was secured by hacking the bark of the trunk for some distance down from the stubs. A sufficient number of the best of these shoots were budded in July by the annular method quickly to develop a symmetrical top. The San Saba variety was chiefly used, the original tree of this standing on Risien's place (Fig. 2824).

Although most early efforts failed, as propagators have acquired experience in pecan-propagation most of the methods of budding and grafting practised on the apple and pear have been found to succeed, so that at the present time practically all except shield-budding are more or less practised. The methods most commonly used by nurserymen are ordinary cleft- and whip-grafting, and annular-, patch-, and chip-budding.

While there has been much discussion of other stocks for the pecan and considerable individual experimentation with mockernut (*Carya alba*), pignut (*Carya glabra*), and water-hickory (*Carya aquatica*), commercial nursery propagation is practically all upon pecan stocks. Nuts from trees of vigorous growth, yielding well-filled kernels, are preferred for seed and should be from a region at least as far north as that where trees are to be planted to insure stocks of sufficient cold-endurance. Nuts for seed should not be permitted to dry out before planting in fall, or, if spring-planted, should be stratified in moist sand soon after harvest. Soil for the nursery should be rich, deep, friable, and well drained, as the control of growth during the

2825. Cleft-grafting. Successive steps in the operation: a and b, views of the cion; c, cross-section of the cion, thicker on one side; d, the cion in place and the stock securely tied to prevent splitting; e, the union covered with grafting wax; f, outer wrapping securely held with string.

propagating season necessitates maintenance of a high state of cultivation with which clods, stones, or continued wetness seriously interfere. Nursery rows should be 5 to 6 feet apart, with nuts planted 8 to 12 inches apart in the row, 2 to 3 inches deep.

When stocks exceed $\frac{3}{4}$ inch in diameter at the point of grafting, cleft-grafting is preferred. If done above

2827. Whip-grafting. Later steps in the operation: *a*, proper method of tying; *b*, improper method of tying; *c*, one year's growth following a successful union.

On account of the length of season during which these methods may be practised, annular- and patch-budding have been widely adopted by pecan-propagators, and special tools for cutting the "rings" and "patches" have come into general use in the southern states (Figs. 2828 and 2829), though expert operators succeed well with the ordinary budding-knife. These methods may be used at any time during the growing season when the bark of both stock and cion "slip" well and the bark and buds of the new growth on the cion trees are sufficiently mature to endure the necessary manipulation. The essentials are good "slipping" condition of both stock and cion, close fitting of "rings" or "patches," secure tying with raffia or other suitable material, careful attention to removal of ties and grad-

2828. A metal tool specially designed for use in annular-budding.

ual heading back of stock as growth proceeds to avoid "drowning out" the bud, and after growth begins the protection of it against splitting off or breaking down by wind and storms, by tying up to stubs or stakes. (Fig. 2830.)

One of the simplest and most effective methods is that long used by E. W. Kirkpatrick, of McKinney, Texas, commonly known as "chip-budding." This may be practised prior to and during the early growing season. Dormant cions are used. It consists essentially of the removal of a "chip" from the stock and its replacement by a bud-bearing chip of approximately identical size from the cion, which is securely tied in

place without waxing. As this method requires only the ordinary budding-knife and is equally applicable to walnut, persimmon, and other species rather difficult to propagate, it is growing in favor, especially in Louisiana and Texas. (Fig. 2831.)

With all methods of budding and grafting, both in nursery and orchard, careful attention to the tying up of the young buds during the first growing season is required. Their soft and luxuriant growth renders them peculiarly subject to destruction by storms, the only effective protection against which is secure tying to stock, stubs, or stakes.

2829. A tool with wooden handle and steel blades specially designed for use in annular-budding.

The large number of seedling trees in orchards and gardens yielding nuts of indifferent quality is arousing much interest in top-working. This can be done by all methods described, but all top-budding or grafting should be as low in the tree as practicable to prevent the head from becoming "leggy" and "prongy."

Successful methods of budding and grafting the pecan are described by Charles L. Edwards, of Texas. The budding method is shown in Fig. 1686, page 1367, Vol. III. The crown-graft or crown-bud is shown in Fig. 2832 and is described as follows: "Buds from wood that has partially lost its vitality, or has been injured by sap starting before it is cut or after it is cut in early spring, may often be saved by this method when all others fail. But the work must be carefully done and instructions strictly observed, for if the bud is lost, the remaining stock is badly disfigured. The stock is cut off bodily at the desired height. A slit is then made at the top, the bark opened, the bud inserted and part of the flaps of bark pared away. Then the wrapper is put on so as to cover not only the cut made for the insertion of the bud, but the top of stump also. The wrapper should cover not only the stump, but should be long enough at the top to pass over and go down far enough on the opposite side to be caught by the string used for tying on the bud. The waxed cloth covering the top of the stump should be pressed down firmly before tying, and if the top of the stump is $\frac{3}{4}$ inch across or more, there should be two thicknesses of cloth put over it and firmly pressed down. On large stumps, two buds may be placed on opposite sides so as to increase chances of a 'take.' If both buds live, one of the shoots may be

2830. Annular-budding. *a*, Bud stick from which the bud has been removed; *b*, the bud ready for insertion in the matrix of the stock; *c*, the stock ready to receive the bud; *d*, the bud after being placed in position and carefully wrapped; *e*, growth taking place, the wrapping having been removed; *f*, growth from the bud supported by being tied to the stock; *g*, above the union. Note the scars above the union, where the buds were removed in order to direct the flow of sap to the new bud.

removed later. In working over-grown nursery seedlings and stout wildings, this has been found to be an excellent plan. With good workmanship and favorable weather conditions, excellent savings may be had, and the bud shoots make a beautiful upright growth, with the slightest crook at the point of union. And, oddly enough, they grow straight without stakes to support them, even in a windy country. Buds put on in March and April on nursery stocks easily make a salable tree with 4 to 6 feet of bud-growth the same season in Texas. In summer work, the modified shield-bud may be peeled from the cion, but it is well to cut them to beveled edges on the sides (D, Fig. 2832) before removing from the cion. The bark of the stock fits down over them more snugly when so treated and they seem to live better. But the lower ends should always be so trimmed as to remove the fleshy rim of bark at the lower end, in order that the inner bark of the bud and the inner bark of the stock may be brought into contact. The flaps of bark folding down over the bud should always be pared down, so that the waxed wrappers may fit close and exclude those pestiferous little insects that get in under other forms of wrapper and destroy so many buds. Another thing requiring eternal vigilance is to be sure that sap is flowing more freely in the stocks than in the budwood."

Distance, method of planting, and cultivation.

The large size of the tree and the lack of any suitable dwarfing stock render wider planting necessary than for other orchard trees. Many of the earlier orchards were spaced at 40 or 50 feet, with some planted as close as 25 feet, with a view to thinning out to 50 feet after some years of bearing. Accumulated experience indicates that upon all soils suitable for the pecan, a distance of 60 feet will be required before the age of maximum productiveness is reached, and that closer

planting than this is inadvisable unless in sections where growth of trees thirty years old and upward indicates that closer distances will not involve harmful crowding and shading, to which the pecan as a nut-bearer is peculiarly sensitive. Well-ripened trees two years from the bud or graft are preferred by most planters and 24 to 30 inches of tap-root is retained in transplanting. In the Gulf States, planting is usually done during the winter months and completed by February, to insure thorough settling of earth and callusing of roots before growth starts. Special care to prevent drying out during shipment and handling is necessary, protection against sun and wind and thorough soaking of roots before planting being advisable.

Holes should be of ample size, 6 to 8 inches deeper than the roots require, and be filled in at bottom with good top-soil. Fertilizer should not be in contact with roots.

The unsatisfactory behavior of close-planted orchards and the necessity of deriving profit from the land during the six to twelve years before the trees come into bearing have given rise to varied practice in intercropping. Peaches, Satsuma oranges, truck crops, cotton, corn, and the like, are used in various sections.

It is essential on most soils to maintain good cultivation throughout the growing season. This is satis-

factorily accomplished with cotton, corn, truck crops, cowpeas or other tilled crops, provided fertility is maintained by adequate fertilizer application and plowing in of leguminous cover-crops. The laying down of pecan orchards in Bermuda-grass for pasture or mowing even on the deep moist soils of the Mississippi Delta has invariably been followed by stunting of growth and lessened productiveness of trees. The use of winter cover-crops such as hairy vetch and bur clover for plowing under in spring has everything to commend it.

Harvesting and marketing.

The preferred practice in harvesting is to permit the nuts to fall as the hulls open, gathering frequently to prevent soiling by contact with the ground. As the efficiency of this method is largely dependent on the continuance of clear and reasonably dry weather throughout the harvest season, it is usually necessary gently to "fhresh" the later-maturing portion of the crop from the trees with bamboo or other light poles. Premature threshing results both in an immature quality of crop and in injury to the trees through the breaking off of fruit-spurs. After gathering, the nuts should be cured by storing in a cool dry place for two or three weeks, during which time there is some loss of weight by evaporation of moisture, after which they are ready for marketing.

A considerable portion of the wild crop is washed and polished by friction in revolving barrels or drums. Some tinting of the nuts with dye is also practised. While polishing and tinting are not in themselves harmful, they have so frequently been used to conceal inferiority of damaged or stale nuts and such as are immature that discriminating purchasers show preference for the nuts in their natural state. This is especially true with* regard to the product of the named varieties, which is coming to be sold on known varietal merit as to cracking quality, plumpness of kernel, flavor, and the like. While the product of cultivated orchards still constitutes but a small proportion of the market supply, it is destined to early and considerable increase.

Marketing by parcel post direct to consumers is coming into practice and coöperative selling by growers' associations is being undertaken to some extent.

Prices of wild nuts have risen considerably in recent years as the result of increased demand from commercial crackers. Prices of the leading orchard varieties, though gradually receding from the fictitious and novelty values of the exploitation period, range from 30 to 50 cents a pound wholesale, with good demand, and retail at 50 to 75 cents in most markets.

Varieties.

The fact that until about 1900 there were few nursery-men able to propagate the pecan by budding and grafting, coupled with the very high prices received for choice nuts from certain individual trees, stimulated the sale of nuts from such trees under varietal names for the planting of seedling orchards throughout the Gulf States. This was true to a large extent with regard

2831. Chip- or "dormant" budding. a, The bud stick; b, the bud ready for insertion; c, the bud inserted in the matrix of the stock; d, the bud securely tied in place.

to Centennial, Rome, Frotscher, Stuart, Russell, Pabst, Jewett, Van Deman, Post, and Hollis, thousands of seedlings of which in dooryards and orchards are now found throughout the South. These seedlings, while frequently bearing a general resemblance to the parent, usually vary widely in important features and, as might be expected, in a large proportion of instances are inferior to the parent variety. Names have in many cases been applied to the nuts of wild trees sold for planting, with the result that much confusion has existed in the varietal nomenclature. The adoption of a code of nomenclature by the National Nut-Growers' Association in 1903, and its systematic application by a standing committee of that organization, has to a large extent clarified the situation in recent years.

The adaptability of varieties to sections, including the important feature of relative resistance to such diseases as scab under varying climatic conditions, is gradually being worked out and is essential to the establishment of commercial pecan-growing on an economically sound basis. At the present time there is much working over of trees of bearing age in progress, with the end in view of replacing the varieties originally planted by those found better adapted to the regional or local conditions.

Out of several hundred named trees, somewhat more than one hundred varieties have been propagated by nurserymen. Of these, many are as yet untested outside of the localities of their origin. Some twenty to thirty sorts have been sufficiently distributed for a long enough time to afford indication of their probable cultural range and value, with the result that a number of the earlier distributed varieties, including Centennial, Jewett, and Rome, and a number of sorts of local repute, have been practically discarded by planters.

The varietal adaptability of the pecan so far as possible to summarize as the result of several years of systematic study in the field was outlined by Reed in 1915 (Farmers' Bulletin No. 700, "Pecan Culture," with special reference to varieties and propagation) as follows:

Varities now considered best for planting in the plains section of southeastern Virginia and eastern North Carolina are the Stuart, Mantura, Van Deman, Moneymaker, Schley, Pabst, and James.

Varities which may be recommended for eastern South Carolina, eastern and central Georgia, central Alabama, and central Mississippi are the Schley, Stuart, Van Deman, Moneymaker, James, and Carman.

Varities for planting in south Georgia and north Florida are the Schley, Curtis, Bradley, Alley, Van Deman, Stuart, Moneymaker, President, Pabst, and Russell.

Varities for central and north Florida: Curtis, Bradley, Kennedy, President, Schley, Van Deman, and Moneymaker.

Varities for the coastal section of Alabama, Mississippi, and Louisiana: Schley, Curtis, Alley, Van Deman, Russell, Stuart, Pabst, Success, and Havens.

Varities for east Texas: Very few sorts have been given a fair trial in this section. The varieties here mentioned are recommended very largely because of their performance farther east. They are the Stuart, Moneymaker, Schley, Curtis, Van Deman, Bradley, Carman, and James.

Varities for west Texas: Sovereign (syn. Texas Prolific), Kincaid, Colorado, San Saba, Halbert, and Burkett.

Varities for northern Louisiana, southern Arkansas, and northern Mississippi: Very few sorts have been given a fair trial in this section. The following varieties are mentioned because of certain evidence of superior hardiness which they have shown and the general merit of the nuts themselves, but they are recommended

for conservative planting only: Moneymaker, Carman, Stuart, Van Deman, Schley, Pabst, and Success.

Varities for the section including central and western Tennessee, central and western Kentucky, southern Indiana, southern and southwestern Illinois, eastern and southern Missouri, southeastern Kansas, Oklahoma, and northern Arkansas: Only varieties of northern or local origin should be considered for planting in this general area, as none of the southern sorts is sufficiently hardy to justify their recommendation. The best of these are the Major, Niblack, Indiana, Busseron, and Posey.

Some of the best known sorts now in the trade, with locality of origin indicated, are the following:

2833. Varieties of the pecan: 1, Moneymaker; 2, Russell; 3, Frotscher; 4, Rome; 5, Alley; 6, Success; 7, Curtis. ($\times \frac{2}{3}$)

Alley (Fig. 2833).—Pascagoula, Mississippi. A thin-shelled nut of medium size, with plump kernel of good flavor. Tree a vigorous grower and heavy bearer, though subject to scab in some locations.

Busseron.—Knox County, Indiana. Recently disseminated and considered promising for Indiana and other northern sections.

Centennial (Fig. 2834).—St. James Parish, Louisiana. The first variety propagated by grafting. Exhibited at Philadelphia in 1876. A large long nut, with rather thick shell and slender kernel. Tree a symmetrical, vigorous grower but very tardy in bearing. Practically discarded in favor of better varieties.

Curtis (Fig. 2833).—Orange Heights, Florida. Though rather small in size, a thin-shelled nut with plump kernel of fine quality. Very productive and popular in Florida.

Delmas (Fig. 2834).—Pascagoula, Mississippi. A large, rather thick-shelled productive variety of very sturdy growth, but rather subject to scab. Kernel plump and of high quality.

Frotscher (syns., Eggshell, Frotscher's Eggshell, Olivier, Majestic) (Fig. 2833).—Olivier, Louisiana. One of the most widely disseminated and distinct of the older varieties. Very large and thin-shelled but with kernel rather dark and unattractive in appearance, frequently not filling well. Rapidly giving way to more reliable sorts.

Hollis (syns., Hollis's Jumbo, Jumbo, Risien, Georgia Belle, Post's Select, in part).—Bend, Texas. A medium to large, roundish

nut, rather widely disseminated for several years as Post's Select. Mainly planted in central Texas.

Indiana.—Knox County, Indiana. Of medium size, with thin shell and kernel of excellent quality. Promising for northern planting.

Jewett.—Pascagoula, Mississippi. Widely disseminated at one time, but generally discarded because of unproductiveness and unthriftiness of tree and unsatisfactory filling of the large long nut.

Kincaid.—San Saba, Texas. A large, oblong nut, with moderately thin shell and plump kernel of fine quality. Scabs badly in South Atlantic States.

Major.—Henderson County, Kentucky. Recently introduced, but considered promising in northern pecan territory. Of only medium size but thin-shelled, with plump kernel of fine quality.

Mobile (syns., Laurendine, Batey's Perfection).—Bayou La Batre, Alabama. A very large and handsome nut, coming into bearing early but not filling well in most sections where tested, and therefore little planted in recent years.

2834. Varieties of the pecan: 1, San Saba; 2, Teche; 3, Stuart; 4, Van Deman; 5, Centennial; 6, Schley; 7, Delmas. ($\times \frac{1}{2}$)

Moneymaker (Fig. 2833).—Mound, Louisiana. A medium-sized, rather thin-shelled nut of excellent cracking and fair dessert quality. A precocious, productive sort. One of the hardiest of the southern varieties.

Niblack.—Knox County, Indiana. Recently introduced. Below medium in size, but its excellent cracking and fine dessert qualities make it promising for the North.

Pabst.—Ocean Springs, Mississippi. A large, rather thick-shelled sort with a very plump and attractive kernel of excellent quality.

Post (syn., Post's Select).—Milburn, Texas. Nuts and seedling trees were widely disseminated for several years under this name, at first from a tree on the Colorado River bottom near Milburn, Texas, later from other trees nearby, and still later from the Hollis tree in the same county. The nut of the original Post tree is of medium size and very attractive appearance and thousands of seedlings from it have been planted throughout the South, but neither the variety nor its seedlings are now propagated.

Rome (syns., Columbia, Columbian, Century, Twentieth Century, Pride of the Coast, Southern Giant) (Fig. 2833).—Convent, Louisiana. One of the largest varieties and for several years the most widely exploited, but now practically discarded by planters. Shell thick and kernel frequently defective.

Russell (Fig. 2833).—Ocean Springs, Mississippi. A medium-sized conical nut with very thin shell. Quality excellent when well filled but often faulty. Tree slender and tender but very productive along the Gulf Coast of Mississippi.

San Saba (syns., Papershell, Risien's Papershell, Royal) (Fig. 2834).—Though small, its thinness of shell, plumpness and sweetness of kernel make it a highly desirable nut where it succeeds. Tree a vigorous, though slender grower; very productive; scabs badly in eastern districts.

Schley (syn., Admiral Schley) (Fig. 2834).—Pascagoula, Mississippi. One of the most widely successful commercial sorts. Nut generally large, with thin shell and plump kernel of excellent quality. Tree pendulous in habit but vigorous and productive.

Sovereign (syn., Texas Prolific).—San Saba, Texas. Seedling of San Saba, larger than the parent, with somewhat thicker shell. Very productive in Texas but susceptible to scab in eastern districts.

Stuart (syn., Castanera) (Fig. 2834).—Widely planted and generally productive. Nut large, filling well but rather difficult to crack and, therefore, less planted as a commercial nut than formerly.

Success (Fig. 2833).—Ocean Springs, Mississippi. A large nut with a relatively thin shell and plump kernel.

Teche (syns., Frotscher No. 2, Duplicate Frotscher, Fake Frotscher, Spurious Frotscher) (Fig. 2834).—Probably a seedling of Frotscher, mixed with that variety in nursery and disseminated as Frotscher. Rather small and not of high quality, but very productive throughout the southeastern states.

Van Deman (syns., Mire, Duminie Mire, Paragon, Bourgeois) (Fig. 2834).—A large to very large nut, cracking well, with plump kernel of high quality. Widely planted in lower Mississippi Valley and Gulf Coast sections. Subject to scab farther east.

Hybrids.—Numerous hybrids of *C. pecan* with *C. laciniosa* and *C. aquatica* are known and some have been named and propagated in a small way. Of these the *McCallister* (syn., Floyd), found near Mt. Vernon, Indiana, is a very large nut, probably the largest known hickory-nut. The original tree has for many years failed to mature more than a small proportion of plump kernels and top-grafted trees of the variety have exhibited the same weakness, so that it cannot be regarded as of commercial value.

Literature.

Books and bulletins have been published on nut- and pecan-culture and varieties. Some of the works are: "Nut Culture in the United States," Division of Pomology, 1896; "The Nut Culturist," A. S. Fuller, 1896; "Nuts for Profit," John R. Parry, 1897; "Pecan Culture for Western Texas," E. E. Risien, 1904; "The Pecan and Its Culture," H. Harold Hume, 1906; "Pecans," J. B. Wight, 1906. Detailed historical accounts and descriptions of forty of the best known varieties, with colored plates, occur in Department of Agriculture Yearbooks for the years 1904-1909 and 1912.

The following bulletins on the pecan have been issued: Florida Experiment Station Bulletins Nos. 54, 57, 85; Texas Experiment Station Bulletin No. 69; North Carolina Department of Agriculture Bulletins Nos. 30, 156, 224; Georgia State College of Agriculture Bulletin No. 82; Georgia Experiment Station Bulletin No. 116; Bureau of Plant Industry Bulletins Nos. 30, 251; Farmers' Bulletin No. 700.

WM. A. TAYLOR.

PECTINARIA (comb-like). *Asclepiadaceae*. The genus as described by Haworth, not of other authors, comprises succulent leafless herbs: sts. tufted, usually procumbent, acutely, obtusely or obscurely 4-8-angled; fls. small, solitary or in fascicles in the grooves or on the sides between the angles; calyx 5-parted; corolla small, budlike, with a short cup-shaped hemispheric or broad and shallow tube and 5 lobes connate at the apex; corona double, outer cuplike and variably cut into 10 to numerous teeth or of 5 minute lobes, inner of 5 lobes incumbent upon the backs of the anthers or erect and about equaling or longer than them and connivent-erect over them; filaments of the stamens connate, forming a tube around the ovary and adnate to the dilated top of the style; follicles narrowly fusiform, glabrous.—Five species, all S. African. The following species have been intro. at Kew: *P. saratilis*, N. E. Br. Sts. acutely 4-angled, with flat or slightly concave sides and distant acute deltoid teeth along the angles; corolla broadly ovoid or subglobose, covered with fine hairs on the inner surface, blackish purple or purple-brown. *P. asperifolia*, N. E. Br. Sts. cylindric, with 6-8 series of closely placed tubercles; corolla papillate outside and within also pentagonally subglobose, with the papillae on the inner surface

covered with short spikelike processes, dull purplish outside, the whole surface inside frosted white, dotted with crimson.

F. TRACY HUBBARD.

PEDDIËA (named after Major Peddie). *Thymelaeaceae*. Glabrous shrubs, hardy in the extreme south of the United States.

Leaves sparse, subcoriaceous or membranaceous: fls. yellowish green, in peduncled umbels at the tips of the branches, pedicelled, perfect; perianth-tube cylindrical, lobes 4 (rarely 5?), short, spreading; stamens 8 (rarely 10?); disk hypogynous, cup-shaped, entire or toothed; ovary glabrous or densely villous at the apex, 2-celled: drupe succulent, with 2 nutlets.—About 10 species, Trop. and S. Afr.

africana, Harv. Shrub: lvs. subopposite, elliptic, nearly sessile, glabrous: fls. in terminal stalked umbels, tubular, $\frac{1}{2}$ – $\frac{3}{4}$ in. long, 4–5-lobed, the lobes revolute: fr. a drupe with 2 stones, ovoid, about 1 in. long. S. Afr.

F. TRACY HUBBARD.

PEDICULÀRIS (from Latin for *louse*; application not evident). *Scrophulariaceae*. LOUSEWORT. Herbs, mostly perennial, sometimes planted in grounds for the showy spikes of flowers and often finely cut foliage.

Mostly erect, only seldom annual or biennial: lvs. alternate or whorled (sometimes opposite), rarely subopposite, 1 to many times pinnately divided, rarely merely dentate: fls. purplish, red, rose-color to white, in spring and summer, borne mostly in a terminal bracted spike; calyx anteriorly cut, variously 2–5-toothed, sometimes also posteriorly; corolla 2-lipped, the upper one (or galea) with or without a long beak, the tube cylindrical; stamens 4, didynamous: caps. ovate or lanceolate, oblique; seeds usually few.—There are about 250 species of *Pedicularis* in many parts of the northern hemisphere (a few S. American), many of them arctic and alpine. Thirty to 40 are native in the

U. S., and the genus has a large extension in Asia. They are little known as garden plants, not being really domesticated. Some of them are adaptable to banks and borders, and others to rock-gardens and alpine work; some are swamp plants. They are likely not to persist long without renewal, as they appear to be partially parasitic and may require a particular host plant. Prop. by seeds and division. The following American species are perennial.

A. *Lvs. undivided: galea long-beaked.*

racemosa, Douglas. Height 12–18 in.: sts. leafy and simple or branched: lvs. lanceolate, undivided, minutely and doubly crenulate: fls. white; galea (upper lip of the corolla) with a long beak ($\frac{1}{2}$ in. long), circinate-incurved, nearly reaching the lower lip. Colo. to Brit. Col.; subalpine.

AA. *Lvs. variously divided: galea with very short beak or none.*

Grayi, A. Nels. (*P. procera*, Gray). Fig. 2835. Robust, $1\frac{1}{2}$ –4 ft. high, leafy: lvs. pinnately divided, the segms. lanceolate and pinnatifid and the lobes again dentate or cut, the radical lvs. 1 ft. or more long: fls. sordid yellowish and greenish striate, in a dense-fld. pubescent spike 10–20 in. long, the galea not beaked; fl.-bracts long. Mountains of Colo. and New Mex.

lanceolata, Michx. SWAMP LOUSEWORT. Glabrous or nearly so, 1–3 ft. high, simple, or branched above: lvs. alternate and opposite, pinnately lobed, upper ones sessile: fls. yellow in a short spike; bracts shorter than the fls.: caps. ovate, scarcely longer than the calyx. Aug.–Oct. Swamps, Conn. to Man., to Ohio and Neb.

canadensis, Linn. WOOD BETONY. The common American lousewort, usually more or less hairy: sts. commonly tufted, $\frac{1}{2}$ – $1\frac{1}{2}$ ft. high: lvs. mostly alternate, oblong-lanceolate, pinnately parted, all but the uppermost petioled, the lobes oblong and obtuse, incised or dentate: fls. yellow or reddish, rarely white, in a short spike that elongates in fr.: caps. lanceolate, 3 times as long as the calyx. April–June. Dry woods and thickets, Nova Scotia to Man.; south, Fla. to Mex. B.B. 3:186. B.M. 2506.

P. cilirostris, Hook. f. Sts. 1 ft. long, very slender and curving: lvs. far apart, 1 in. or less long, pinnatifid, the lobes 3 or 4 pairs and incised: fls. rose-colored, axillary, long-pedicelled, the stalks recurving in fr. Himalaya, 10,000 ft. B.M. 7735.—*P. foliosa*, Linn. Sts. simple, 1–3 ft.: lvs. pinnatifid, the segms. lanceolate and toothed: fls. cream-color, in a dense spike; galea very blunt. Eu. Gn. 62, p. 97.—*P. mollis*, Wall. Annual, 2–3 ft., strict: lvs. all on the st., ovate or oblong, pinnatifid, the segms. linear and crenate or pinnatifid: fls. dark pinkish purple, in strict spikes 6–16 in. long. Himalaya, Thibet, 10,000–14,000 ft. B.M. 4599. J.F. 2:166.—*P. Sceloporum-Carolinum*, Linn. St. few-lvd., 3–4 ft.: lvs. pinnatifid, the lobes ovate and crenulate: fls. golden yellow, 1 in. long, in an interrupted spike, the lower lip tinged red. Eu. G.C. III. 40:385.—*P. siphonantha*, Don. Sts. 1 ft. high or less, erect or ascending: lvs. radical, linear-oblong, pinnatifid: fls. red or pink, axillary and in terminal racemes, the corolla-tube 1–6 times as long as calyx. Afghanistan to Thibet.

L. H. B.†

PEDILÁNTHUS (Greek, *shoe-flower*). *Euphorbiaceae*. SLIPPER PLANT. BIRD CACTUS. REDBIRD CACTUS. SLIPPER SPURGE. JEW BUSH. Low tender cactus-like shrubs, grown in collections of succulents.

Stems thick and fleshy, juice milky: lvs. alternate, often rudimentary, the midrib thickened and often keeled below: infl. of terminal or axillary cymes; the fl. and fr. characters as in *Euphorbia*, but the involucre with a deep fissure and a short spur on the upper side, the spur containing the glands.—About 30 species in Trop. Amer. Prop. and cult. similar to the succulent *euphorbias*. See Millspaugh in Field Museum Nat. Hist., Publication 172, 1913, for a revision of the species.

A. *Lobe of the involucre above the spur entire.*

tithymaloides, Poit. (*Euphorbia tithymaloides*, Linn. *E. canaliculata*, Lodd. *E. carinata*, Donn). St. 4–6 ft. high: lvs. dark green, ovate or oblong, acute; midrib keeled below and dentate: involucre bright red or

2835. *Pedicularis Grayi*. ($\times \frac{1}{2}$)

purple, $\frac{1}{2}$ – $\frac{3}{4}$ in. long, in dense terminal cymes, glabrous inside and out; pedicels of the stamens hairy, of the ovary smooth. Fla. to Venezuela. B.R. 837. L.B.C. 8:727. B.M. 2514.—Two varieties are in cult., *cuculátus* and *variegátus*, Hort., both with white-bordered lvs.

padifólius, Poit. Sts. green, glabrous; lvs. few, oblong-ovate, obtuse; cymes terminal, open; tube of the involucre hairy only within; pedicels of both stamens and ovary hairy. W. Indies.

AA. Lobe above the spur 2-parted; bracts of the infl. green.

aphýllus, Boiss. Branches slender, leafless; cymes terminal; the pubescent peduncle attached at the back of the involucre, which is hairy within; pedicels of the stamens and ovary glabrous. Mex.—Intro. as a wax-yielding plant.

macrocárus, Benth. Shrubby; sts. whitish; lvs. minute; cymes open, few-fl.; peduncle attached to the center of the involucre, pedicels glabrous. W. Mex.

J. B. S. NORTON.

PEDIOCÁCTUS (*plains cactus*). *Cactaceæ*. Globular, resembling in habit and flower the so-called *mammillarias*; fls. small, with a rather indefinite funnel-shaped tube; petals pinkish, broad; sepals smaller than the petals and duller in color; bracts on corolla-tube few; stamens numerous; ovary green, nearly globular, usually without bracts (rarely 1, otherwise naked), apex with a truncate or depressed scar left by the deciduous corolla; fr. dry, greenish, bursting irregularly; seeds dull black, tuberculate, keeled on the back, with a large sub-basal hilum. The fl. originates just above the spine areole on the very young tubercles, and therefore this genus belongs to the *Echinocactus* type rather than to the so-called *mammillarias*. The seeds are also of the *Echinocactus* type.

Simpsonii, Brit. & Rose. Subglobose or depressed, turbinate at base, simple, often clustered, $3\frac{1}{2}$ –5 in. diam.; ribs 8–13, only indicated by the spiral arrangement of the prominent tubercles, which are $\frac{1}{2}$ – $\frac{3}{8}$ in. long, somewhat quadrangular at base and cylindric above; exterior spines 20–30, slender, rigid, straight, whitish, $\frac{1}{8}$ – $\frac{1}{2}$ in. long, with 2–5 additional short setaceous ones above; interior spines 8–10, stouter, yellowish and reddish brown or black above, erect-spreading, $\frac{3}{8}$ – $\frac{3}{4}$ in. long; no truly central spine; fls. $\frac{3}{4}$ – $\frac{1}{2}$ in. long and nearly as broad, yellowish green to pale purple. Mountains of Colo., Wyo., Utah, and Nev.—This species does not grow well in cult., although it is frequently intro. This is the species which forms the "snake cactus" or "brain cactus" often seen in cult.

J. N. ROSE.

PELARGONIUM (*stork*, because the fruit is long and slender like a stork's bill). *Geraniaceæ*. GERANIUM of gardens. PELARGONIUM. STORK'S BILL. Many kinds of pot-plants, popular for indoors and for bedding; and some of them much planted permanently out-of-doors in California and elsewhere; flowers showy.

Plants of various habit: some are fleshy and tuberous and are treated as succulents, but those commonly grown are erect or trailing leafy herbs or woody below (sometimes shrubby) with sts. somewhat soft and succulent or small and firm; lvs. mostly opposite, entire to decompound, stipulate, the foliage often strong-scented; infl. mostly umbel-like, on axillary peduncles; fls. irregular, the petals 5 (rarely fewer by abortion), the 2 upper usually larger and more prominently colored, the lower mostly narrow and rarely very small, the colors pink, red, purple, white, sometimes yellow, often attractively blotched or veined; calyx 5-parted (or the sepals said to be connate at base), the uppermost segm. produced at base into a slender nectar-bearing tube or spur adnate to the pedicel; stamens 10, of which 7 or less are anther-bearing and fertile; fr. of 5 valves, each 1-seeded and separating from the beak-

like apex mostly by coiling and more or less hygro-metrically.—Nearly all the pelargoniums are from S. Afr. All the species mentioned in this article are from that region, unless otherwise stated. Harvey, in Vol. I of Harvey & Sonder's *Flora Capensis* (1859–60), admits

2836. *Pelargonium inquinans* (and a variety of it) as figured by Dillenius in 1732.

163 species; and his descriptions are followed closely in the characterizations of species given below. Knuth, the most recent monographer (in Engler's *Pflanzenreich*, IV. 129, 1912), admits 232 species and very many well-marked hybrids. *Pelargonium* is distinguished from the genus *Geranium* by technical characters. In most cases, the fls. of *Geranium* are regular, but those of *Pelargonium* are irregular, the 2 upper petals differing from the others in size and shape and often in coloring. The most constant difference between the two genera is the presence in *Pelargonium* of a nectar-tube, extending from the base of one of the sepals and adherent to the side of the calyx-tube or pedicel. This tube is not seen by the casual observer, but it may be discovered by making a longitudinal section of the fl. and pedicel.

The person who wishes to study the contemporaneous evolution of plants may find his heart's desire in *Pelargonium*. With great numbers of species and many

of them variable and confusing in a wild state, with plant-breeding in many places and continued through two centuries, and with a large special literature, the genus offers exceptional advantages and perplexities to the student. Most of the species early came into cultivation by the English and Dutch, the South African plants forming at one time almost a separate department of horticultural knowledge. *P. cucullatum*, the dominant parent in the florist's pelargoniums, was known in England as early as 1690. The two originals of the race of zonal or bedding geraniums were introduced into England in 1710 and 1714. Early in that century, a half-dozen species were grown at Eltham, in the famous garden of James Sherard, and these were pictured in 1732 in Dillenius' account of that garden, "Hortus Elthamensis," a sumptuously illustrated work in quarto. Even at that time, *P. inquinans* had varied markedly (see Fig. 2836). In his "Species Plantarum," 1753, Linnaeus described the few species which he knew (about twenty-five) under the

2837. Gardener's ideal, and the original form, as depicted in 1841.

genus *Geranium*. In 1787, L'Heritier founded the genus *Pelargonium*, and transferred many of the Linnaean species. L'Heritier's work "Geraniologia," a quarto, appeared in Paris in 1787 to 1788, with forty-four full-page plates. Recently Kuntze has revived the pre-Linnaean name *Geranospermum* (1736) for this genus, but it is not likely to find acceptance.

Early in the nineteenth century, many species were in cultivation in Europe, and experiments in hybridizing and breeding became common. There appears to have been something like a geranium craze. The experiments seem to have been confined largely to the development of the show or fancy pelargoniums, as greenhouse subjects, for bedding plants had not reached their present popularity. The geranium interest seems to have culminated in Robert Sweet's noble work on "Geraniaceae," published in five volumes in London, 1820 to 1830, containing 500 well-executed colored plates of geraniaceous plants. At that time many distinct garden hybrids were in cultivation, and to these Sweet gave Latin botanical names. His fifth volume is devoted chiefly to garden forms of the show pelargonium type, to which the general class name *Domeesticum* is given in the following sketch. The development of the zonal or bedding geraniums had begun in Sweet's time, and he includes them in his pictures, but the larger part of their evolution is subsequent to his history. Various small works on pelargonium have appeared. De Jonghe's "Traité Méthodique de la Culture du Pélaronium," Brussels, 1844, contains good bibliographical and cultural data.

Few classes of plants should have more interest to the amateur and fancier because the species are numerous and varied, the colors mostly very attractive, the habit of the plant interesting, and the foliage often with pleasing fragrance; yet, excluding the common window and bedding geraniums of the *P. zonale* and *P. inquinans* type and the Lady Washington or Show types, they are very little known to gardeners. A cool greenhouse could be made to yield very interesting subjects in the species here described and others that may be secured from collectors in the regions where they grow.

Most of the cultivated forms of pelargonium may be grouped into four general horticultural classes:

I. The zonal, horseshoe, fish, or bedding types, known to gardeners as "geraniums." They comprise a mongrel class, designated as the *Hortorum* class

This race seems to be derived from *P. zonale* and *P. inquinans*. These two species were made by Linnaeus in 1753, but he founded them on descriptions in earlier works rather than directly on the plants. In America, the zonal geraniums are very popular, for they develop their colors well in the bright climate. They are popular in all countries, however. They probably stand closer to the lives of a great number of persons than any other ornamental plant. If a window or a garden can have but one plant, that plant is likely to be a geranium. The old race of large-flowered and large-clustered geraniums was known as "nosegay geraniums," because they were bouquet-like, but this term is not known in America. Another race has been developed for its zone-marked leaves. There is also a race of double-flowered

zonals, which have appeared chiefly since 1860. The very full double and close-clustered forms lose much of the grace and charm of the single types. Some of them are little better, to a sensitive eye, than balls of colored paper. In the development of the individual flower of the geranium, there have been two ideals—the English ideal for a circular flower with the petals broadened and overlapping, and the continental ideal with a somewhat two-lipped flower and the petals well separated. In the "Gardeners' Chronicle" in 1841, p. 644, the proper form is set forth in an illustration, and this is contrasted with the "original form;" the picture is reproduced, somewhat smaller, in Fig. 2837. "The long, narrow, flimsy petals of the old varieties," the writing says, "moved by every breath of wind, and separated to their very base by broad open spaces, have been succeeded by the beautiful compact flowers of the present day, with broad stout petals so entirely overlaying each other as to leave scarcely an indentation in the outline of the flower; while the coarseness which prevailed in the larger of the old sorts is replaced by a firmer substance, and a far more delicate texture." Fig. 2838 shows contrasting ideals, although the picture does not represent the extremes.

2838. Three forms of garden geranium. The upper two show the two-lipped ideal. Uppermost is Mrs. E. G. Hill; middle one, *Maculatum*; lowest, *Wistrie*.

In more recent years a French type has ap-

LXXXVI. The common garden geranium, a form of *Pelargonium*.

peared under the name of "gros bois," or "large-wood" race. It is characterized as follows by Dauthenay: umbels ordinarily 4 to 5 inches in diameter: flowers very large; petals roundish, or sometimes triangular, the limb always very large and giving the corolla a remarkably round contour: leaves very large, thick and coriaceous, plane or incurved, more or less indented, strongly nerved, their diameter averaging about 5 inches, pedicels large and short; peduncles large, rigid, and projecting beyond the foliage: wood soft, fleshy, very large, often $1\frac{1}{2}$ inches around. To this type Dauthenay refers the Bruant geraniums, dating from 1882. A special handbook is devoted to these plants: Dauthenay, "Les Géraniums," Paris, 1897.

2839. *Pelargonium peltatum* ($\times \frac{1}{2}$). No. 7.

II. The ivy-leaved geraniums, products largely of *Pelargonium peltatum* (Fig. 2839). The species is said to have been introduced into England in 1701. It is a weak and straggling plant, used mostly in vases, hanging-baskets, and other places in which an overhanging subject is desired. The foliage is thick and shiny, slightly peltate and prominently angle-lobed, and the pink or reddish two-lipped flowers are always admired. Much-improved and double forms are now in commerce.

III. The "show" or fancy type is known to gardeners as "pelargonium," and in this country also as Lady Washington geraniums (Fig. 2845). These plants are very popular in Europe, being grown in numerous varieties. They are prominent at the exhibitions. Because of the hot trying summer climate, these plants are of very secondary importance in America, although there are many gardeners who succeed well with them. This race of pelargoniums seems to have descended chiefly from *P. cucullatum*, although *P. angulosum* may be nearly equally concerned in it. *P. grandiflorum* is also thought to have been a formative parent. It is probable that two or three other species are concerned in the evolution. In fact, the late Shirley Hibbard once wrote (G.C., July 3, 1880) that "it must be evident to every cultivator of these flowers that the blood of a score or so of species is mingled in them." This marked garden race, which represents no single wild species, is designated as the Domestic group.

IV. Various scented-leaved geraniums, known mostly as "rose geraniums." These are of several species, with their hybrids and derivatives. The common rose geraniums are nearest *P. graveolens* and *P. Radula*. The nutmeg geranium is *P. odoratissimum* or *P. fragrans*.

Aside from the above groups there are several species which appear sporadically in the trade, as *P. tomentosum*, *P. echinatum*, *P. triste*, *P. quinquevulnerum*, *P. fulgidum*, and *P. quercifolium* or the derivatives of them. Few great collections of pelargonium species and varieties have been made in this country, and this is much to be regretted.

Culture of zonal geraniums. (C. W. Ward.)

While the general florist may consider geranium-culture the easiest of all gardening, the fact remains that it is as necessary to observe the requirements of the geranium as it is to observe the requirements of any other plant, in order to succeed and produce the best effects attainable. While it is true that the geranium will grow and make a good showing with comparatively little care, there is as much difference between a skilfully grown geranium plant and one carelessly grown as there is between a fancy and a common rose or carnation.

To secure the best results it is necessary to propagate from perfectly healthy stock. The dangers of over-propagation are as great with the geranium as with most other plants. To keep most varieties in good health it is necessary to plant the stock intended for propagation in the field and to propagate either from the field-grown wood in August or early September, or to lift the plants in the month of September and plant them on benches in the greenhouse, where they will become established and will maintain a vigorous constitution throughout the winter season. The propagation from field-grown wood is far less successful than from wood grown inside, and when the field-grown cuttings are placed in sand, a large percentage of them is likely to damp-off, especially if there has been a comparatively abundant rainfall in the month of July. The best method that the writer has found for striking the field-grown cuttings is to put them in 2-inch pots, using a light sandy soil free from all manure and chemicals, and to place the pots in the full sunlight either in a coolhouse or a frame. These cuttings must be kept on the dry side until the calluses have been well formed, although they should not be allowed to shrivel at any time. If the cuttings show signs of shriveling, a light syringing is preferable to a heavy watering. After the roots have started, the treatment of the plants is the same as if the cuttings had been rooted in the sand and repotted. The writer considers wood grown inside superior to field-grown wood, as the cuttings are much shorter-jointed; most of them can be taken from the plant with a heel and 95 to 100 per cent of them will root in sand in the ordinary cutting-bench.

A good temperature for the geranium propagating-house is 56° to 60° , with a bottom heat of 65° to 68° . While the cuttings are in the sand and before they are rooted, care must be taken about keeping them too moist for fear of "damping-off," or what geranium-growers know as "black-rot." As soon as the cutting is thoroughly callused and begins to emit roots, it should be potted up at once. The best soil for geraniums, according to the writer's experience, is a firm pliable clay loam; this is best if used absolutely without any manure, especially fresh manure. After potting the cuttings they should be lightly watered and shaded for a day or so if the sun is extremely hot, until the roots take hold and the foliage fills up and the stems begin to look plump. The geranium should not be grown at any time in its young state in a soil that is too rich, and care must also be taken that the plants are not kept too wet.

The geranium is subject to few diseases, and so far as the writer has been able to observe these diseases are brought on by improper treatment, such as having too much fresh rank manure in the soil or keeping the plants too wet. Too much strong plant-food in the earth combined with too much moisture induces a condition of the leaves ordinarily called "spot." It usually appears in the hottest weather or immediately after extreme heat accompanied by copious showers or rains.

Excellent specimen geranium plants may be grown in pots, especially of some of the newer French and English round-flowered varieties. In order to produce the best results, choose young vigorous plants that have

been propagated either in the latter part of August or the forepart of September, and that have shown a disposition to take hold immediately, both in rooting and in starting to grow after being potted. The soil should not be too rich, and it is best to start with the plant in a rather small pot, say 2½ inches, and proceed onward with light shifts,—that is, shifting the plant from a 2½-inch to a 3½-inch pot, and so on, letting the sizes increase an inch at each shift until a 7-, 8-, or 9-inch pot is reached, which will usually be large enough to flower the finest specimens. Whenever shifting the geranium, be sure to pot firmly, as a firm soil produces a short-jointed stocky growth, and far more bloom than a loose or over-rich soil. When the plants reach a 5- or 6-inch pot they may be regularly fed with manure-water. The most critical time for these specimen geraniums will be in the months of July, August, and September; in these periods exposure to intense sunshine should be avoided. Too much water and a close temperature are always detrimental to the geranium. Syringing the foliage frequently to keep down the temperature is also injurious. If these plants are kept under glass, a light shading or stripping upon the glass is beneficial. Probably the best position for such plants in these three extreme months is on the north side of a row of trees, some distance away from the trees, where the plants will have the benefit of the subdued shading of the foliage. If kept under glass and shaded, abundant ventilation should always be provided. As the winter approaches, a night temperature of 60° and day temperature of 70° to 75°, with plenty of ventilation in the daytime, especially in bright weather, seem best to suit the plants. Syringing ruins the flowers, and too much moisture either in the pot or upon the foliage causes the spotting of the leaves known as "dropsy." In planting the geranium in the field or in beds, always avoid an over-rich soil. The earth should be in good condition and fertile, but must not be loaded with either chemical or animal fertilizer. Too much water at any period during the hot weather produces a rank growth, reduces the quantity of bloom and in most instances induces the spotted foliage to appear.

Another disease, which is sometimes serious, especially in extremely hot seasons accompanied with a superabundance of moisture, is "stem-rot." This frequently attacks imported stock. It is most serious in intensely hot seasons; the entire plant turns black and fades and withers away. The stem-rot occurs in varieties that have been very heavily propagated.

The insects that affect the geranium are also comparatively few. The red-spider is sometimes a serious pest in summer and is difficult to get rid of when it is once well established. The only method is to syringe the plants with an extremely fine spray, and also to pick off

the leaves that are seriously affected and burn them. The green-fly is also troublesome at times, but is easily managed with the ordinary fumigation of tobacco. There is a small caterpillar that eats the foliage and sometimes proves a serious pest. If one can induce a few ground sparrows or any of the warblers, or even English sparrows, to make their home about the greenhouse, they will put a speedy end to these caterpillars. Another remedy is to go over the plants carefully and to pick the caterpillars off and destroy them. This is tedious, as it must be done frequently.

In the way of bedding geraniums, as a rule the Bruant section produces the best results, but there are a number of English and French varieties that do especially well in our hot climate. The greatest difficulty in successful geranium-culture in America is the intense heat of the summer months, chiefly July and August. Some varieties withstand the heat better than others.

Show pelargoniums. (T. D. Hatfield.)

What are known as show pelargoniums have enjoyed a long popularity. By the general public, and by old people especially, they are known as Lady Washington geraniums. They are not so commonly grown as the so-called geraniums, chiefly on account of their limited season of bloom and the fact that they cannot endure our hot midsummer suns. Through the greater part of the summer they are liable to be neglected. They also require different treatment from geraniums, and—if skill there be—more skill in cultivation.

At the end of the blooming season, they require rest,—a season of ripening the growth already made. At this time very little water will be needed, and they may be stood out in the full sun. Only the old flower-stems may be removed. In no sense should they be cut back at this time, neither should water enough be given to encourage new growth. All the leaves should stay on until they naturally turn yellow with age, thus securing a thoroughly ripened growth. In September, one may prune them into shape, sometimes rather severely, but in any case cut out all weak and soft shoots. They should then be shaken out and repotted in a light compost, not rich, into the smallest-sized pots that will hold them, for the process of growing them on has to be gone

over every season. After potting, a good soaking will be necessary, and they may be placed in a well-lighted coldframe. There is no need to keep them close; the stimulation of water, and the slight protection of a frame are usually enough to start them into new growth. No forcing will ever be needed at any season, and if the grower wished, he might keep them in a cold-frame until very late in the season, so long as adequate protection against frost is afforded. They are at their best in May, and to have them in good condition, one may grow them slowly in a house averaging about

2540. Leaves of various fancy-leaved geraniums.—Hortorum ($\times \frac{1}{2}$). No. 13.

50° night temperature (slightly less in midwinter), from October onward.

After the turn of the days—in January—re-pot them, using now a richer compost. Give a fairly good shift, depending in part on the size of plants desired, the vigor they show, and the difference in varieties. If wanted to bloom in April or, as some florists might, at Easter, they should have been potted at once—in late August or September—into the size they should bloom in,—a medium size, probably the same as they had lately occupied, and have

2841. *Pelargonium odoratissimum*
(Natural size). No. 15.

been taken indoors to grow on continuously. But for display in May and June, they are potted again in January, and some plants may be given another shift when extra vigor or the possible need of a few extra-large specimens demand it. They will need careful stopping. Some rubbing out of weak shoots, when they break abundantly, will help those that remain, and one may even have to do a little pruning. Stopping, however, must be discontinued as soon as the flowering stems begin to show, which is about the end of February in the writer's practice. These stems can be distinguished easily by a slightly different manner of growth. Up to this time the plants may be allowed to grow naturally; but if the gardener wants trained specimens he must begin to bend them as he wishes them to grow, as their growth speedily hardens and the plant will readily take and keep the form to which it is shaped.

Water should be given sparingly through the dead of winter. February and March are the months when the most growth is made, and at this time one may stimulate them materially by the judicious use of artificial manures, which may be continued, if necessary, until they come into bloom. They are much subject to the attacks of green-fly and red-spider; and as the foliage is fairly tender and liable to injury from tobacco smoke, reliance must be placed on fluid insecticides almost wholly. The blooming season is very much lengthened by giving a slight degree of shade.

The best time to take cuttings is soon after the flowering season. Often toward the last of the season, the plants make a few "growing" shoots, and these may be taken; but off and on during the summer one can get cuttings, and any time until August will do. Cuttings taken in winter-time with a heel make pretty little plants in 4- or 5-inch pots without stopping. Cuttings taken at the usual time and grown in 6- or 7-inch pots come in handy in grouping for the front lines. It is necessary to raise a few plants every season to replace older plants which have grown too large.

New varieties are raised from seed, which is freely produced. In hybridizing it does not appear that hand-

pollination has any effect, as the seedlings seldom show any particular affinity to either parent.

I. Lvs. on the pinnate order, although sometimes entire, usually pinnately lobed or compound. (Nos. 1-5).

A. Plant with short, more or less succulent st. and tuberous or thickened roots: lvs. pinnate or pinnately parted, long-petioled: fls. in many-fld. dense umbels, on very short pedicels; petals 5, nearly equal; stamens 6-7, one filament broad. (Polydactylum.)

1. *triste*, Ait. (*Geranium triste*, Linn. *G. pastinacæfolium* and *P. villosum*, Mill.). St. or caudex very short, succulent: lvs. large, 2-3 pinnately compound, pubescent, the ultimate teeth gland-tipped: calyx-tube long and stalk-like, much exceeding the pedicel, the lobes half as long as the petals: fls. brown-yellow with dark spots.—A well-marked species, sometimes offered in the trade. It runs into several forms. The various names and synonyms suggest the divided lvs. of the umbellifers and other plants. Var. *filipendulifolium*, Sims. Caulescent: lvs. sub-bipinnatifid, the segms. oblong. B.M. 1641. Var. *daucifolium*, Harv. (*Geranium daucifolium*, Linn.), has lf-segms. narrow-linear or linear-oblong. Var. *laxatum*, Harv., has lvs. 4-pinnate, the pinnæ stalked and ultimate segms linear.

2. *quinquevulnerum*, Willd. Somewhat shrubby at base, sparingly branched, hirsute: lvs. 2-pinnatifid with linear toothed segms., the stipules broadly cordate and mucronate: fls. purple, scentless, the petals obovate, velvety, and pale-edged; calyx-tube as long as the pedicels, somewhat hairy, the lobes obtuse.—Thought by Sweet to be a hybrid of *P. triste* and *P. bicolor*, and so regarded by Knuth.

3. *fulgidum*, Ait. (*Geranium fulgidum*, Linn.). St. shrubby, densely pubescent: lvs. pinnately 3-parted, silky on both sides, the lateral segms. 3-lobed, all

2842. *Pelargonium cordatum* (× $\frac{1}{3}$). No. 18.

deeply toothed, the terminal lobe oblong and pinnatifid; stipules acute, broadly cordate: peduncles usually branched, many-fld.; fls. small, bright scarlet, the petals obtuse; calyx-tube conspicuously swollen at the base and again just underneath the fl., thrice as long as the pedicel, the lobes linear-obtuse; petals brilliant scarlet with dark lines.—Perhaps not now seen in its pure form, but it is probably a remote parent in various small-fld. scarlet geraniums. Cult. in England as early as 1723.

2843. *Pelargonium cordatum*. Leaves often are much more cordate at base. ($\times \frac{1}{2}$)

appears not to be in the trade, at least not in a pure form.

5. *artemisæfolium*, DC. (*P. artemisioides*, Hort.). Suffrutescent, erect and slender, glabrous, nearly simple: lvs. long-petioled, 2-pinnately parted, nearly glabrous, the segms. linear-filiform and channeled; stipules free, subulate: peduncles long, 2-3-fld.; fls. white or bluish; calyx-tube swollen at base, 2-3 times as long as the lance-cuspidate segms., not ribbed; petals about twice longer than calyx-segms. or sepals, spatulate or obovate, rounded at apex, more or less veined and spotted at base. G.M. 54:629.

II. Lvs. on the palmate order, although sometimes entire, usually lobed (Nos. 6-31).

A. Plant shrubby, or sometimes succulent and jointed: lvs. palmately nerved or lobed; stipules persistent and either rigid or membranaceous: petals 4 or 5, the two uppermost broadly obovate and long-clawed, very much longer than the lower ones; fertile stamens ?. (*Jenkinsonia*.)

6. *Endlicherianum*, Fenzl. Herbaceous perennial, 1-1½ ft. high, noteworthy in being W. Asian: st. little branched, somewhat fleshy, terete, pubescent: basal lvs. more or less numerous, glaucous, cordate-orbicular, broadly and obscurely 5-lobed, lobes crenate-dentate, with whitish appressed hairs; stipules lanceolate, hairy: fls. many in the umbel, rose-colored; spur of calyx exceeding pedicel; upper 2 petals 2-3 times longer than sepals. Asia Minor, Syria. B.M. 4946. G.C. III. 30:149. Gn. 60, p. 185. G.M. 52:214. H.F. II. 7:71.

AA. Plant weak and usually trailing, the branches slender and not succulent: lvs. thick or fleshy and glossy, lobed, mostly marginally peltate: infl. umbellate; good stamens ?, 2 upper shorter; petals unequal. (*Dibrachya*.) IVY-LEAVED GERANIUMS.

7. *peltatum*, Ait. (*Geranium peltatum*, Linn.). Fig. 2839. Plant with slender-jointed more or less zigzag

angled sts. which are glabrous or very nearly so (except at the top): lvs. glabrous or minutely pubescent, fleshy, the petiole inserted just inside the margin at the base, about 5-nerved and with 5 short wide mostly obtuse main lobes and often with smaller minor lobes or angles and notches, the margins very entire: peduncle very long, originally 4-8-fld., but now bearing many greatly modified fls., the calyx-tube slender and stalk-like, often longer than the pedicel and 2-3 times longer than the pointed nerved and mostly ciliate lobes; petals twice as long as calyx-lobes, red to white or purplish, the 2 upper ones erect and purple-blotched or striped, the 3 lower ones usually smaller and not marked and separated from the upper as if the fl. were 2-lipped B.M. 20.—Parent of the ivy-leaved geraniums, now much improved and varied. Prized for baskets. There are forms with double fls. and colors of various kinds. It is a most desirable plant and very floriferous in most of the garden sorts. In the wild there are the following forms: Var. *glabrum*, Harv. Calyx and foliage glabrous: fls. purplish pink. Var. *scutatum*, Harv. (*P. scutatum*, Sweet). Calyx villous: lvs. glabrous. Var. *clypeatum*, Harv. (*P. clypeatum*, Steud.). Calyx and lvs. soft-pubescent. P. *latéripes*, L'Her. (*P. hederæfolium*, Salisb.), has lvs. cordate, not peltate.

AAA. Plant woody or herbaceous, with slender sts.: lvs. very long-petioled, palmately 5-7-nerved, lobed or cut; stipules free, ovate or lanceolate: petals unequal, the two upper ones broad; fertile stamens ?, unequal. (*Eumórpha*.)

8. *grandiflorum*, Willd. Shrubby, glabrous and glaucous: lvs. long-stalked, strongly 3-7-nerved from the top of the petiole, deeply 5-7-lobed, the lobes broad

Geranium Africa arborescens, foliis cucullatis angulosis.

2844. *Pelargonium angulosum*. From Dillenius' figure in 1732. (One-half the size of the original plate.) No. 20.

and sharp-toothed, the stipules ovate and mucronate: fls. about 3 on each peduncle, the stalk-like calyx-tube 3-4 times as long as the lanceolate segms., the obovate white petals (upper 2 with red lines) 3 times as long as calyx-segms.—A handsome and distinct species, probably not now in cult. in its pure form. Intro. to England in 1794.

9. *multibracteatum*, Hochst. Somewhat shrubby below, 1-2 ft., thinly hairy but becoming glabrous: lvs. palmately about 7-cut or -lobed, the segms. broadly oblong or ovate, serrate or crenate, more or less hairy, 2-5 in. across; stipules about $\frac{1}{2}$ in. long, ovate to elliptic: peduncles long, 6 in. to 1 ft., bearing 6-10-fld. umbels; fls. whitish or white, on pedicels about $1\frac{1}{2}$ in. long; petals obovate-spatulate, entire, twice longer than the narrow sepals. Trop. Afr. G. M. 54:628.

10. *transvaalense*, Knuth (*P. Thornecroftii*, Hort.). Erect, 16 in. to 2 ft. in bloom, the st. terete and soft-hairy, sparingly branched: lvs. few, cordate-angular in outline, 5-7-lobed, the lobes triangular or rhomboid, serrate-dentate, the petiole as long as blade or longer; stipules broadly ovate, acute: umbels many, corymbose at apex of st.; fls. nearly sessile, rose-colored or carmine-rose, or pale pink, $1\frac{1}{2}$ in. across vertically, the 2 larger petals strongly narrowed at base and emarginate at top, the 3 smaller ones paler and retuse or emarginate. Transvaal, 3,000 ft. altitude. G.C. III. 55:103.

AAAA. Plant with thick succulent branches, and strong fishy odor, shrubby in the wild and in warm countries: lvs. obovate, orbicular or reniform, shallowly if at all lobed: infl. umbel-like; good stamens 7, the 2 upper ones short; petals typically all of one color. (*Cicónium*.) FISH or BEDDING GERANIUMS.

11. *zonale*, Willd. (*Geranium zonale*, Linn.). ZONAL or HORSESHOE GERANIUM. Shrubby, becoming woody at the base even in pots, the young branches succulent and somewhat hispid: lvs. round-cordate, glabrous or pubescent, long-stalked, usually with a zone or horseshoe mark of deeper color on the upper surface, the margin crenate-dentate, with several very shallow rounded lobes; stipules broad, cordate-oblong: peduncles long, the many fls. nearly sessile; calyx-tube glabrous or nearly so, 4-5 times longer than the lanceolate segms.; petals separated, narrow-wedge shape or spatulate.—S. Afr., "among shrubs and on hillsides. . . . The fls. vary from scarlet and crimson through

all shades of red to pure white."—Harvey. Probably originally red. *P. zonale* was intro. into England in 1710. Linnaeus described it in 1753 as *Geranium zonale*, founding the species on previous descriptions, not on specimens. It is probable that the species had been considerably modified by domestication when Linnaeus wrote. There seems to be no accepted early portrait of the original form of the plant.

12. *inquinans*, Ait. (*Geranium inquinans*, Linn.). FISH GERANIUM. Fig. 2836. Plant more velvety than *P. zonale*, sometimes more or less viscid, the lvs. not zoned: lvs. long-petioled, orbicular-reniform, crenate, only obscurely many-lobed, velvety and somewhat viscid: calyx-tube densely glandular and viscid, 3-4 times longer than the lanceolate segms.; petals broadly obovate, scarlet, but now varying to lighter colors.—"Among shrubs and on hillsides." This is the *Geranium inquinans* of Linnaeus, who founded the species on previous descriptions. One of the descriptions (Dillenius, in "Hortus Elthamensis," 1732) was accompanied by a picture, and this picture, reduced, is reproduced in Fig. 2836. It will be seen that even in that early day the species had varied into a form with short-notched petals and short pedicels. Intro. into England in 1714. Said by Harvey (1859-60) to be the parent of most of the "scarlet geraniums" of English gardens.

13. *hortorum* class. COMMON FISH or BEDDING GERANIUM. Fig. 2840. The common geranium in great numbers of forms, derived from the variation and probably the blending of *P. zonale* and *P. inquinans* (and possibly others) in more than a century of careful selection. The original species are not now in cult. Practically all garden geraniums have the zonal marks on the lvs., or bands, or a central blotch of variegation. Some of them have intermingled colors of green, white, and red on the same lf. Some are "silver-banded" and some "gold-banded." (See Fig. 2840.)

AAAAA. Plant with a short and thick more or less fleshy st. or caudex, from which arise slender branches, the lvs. long-stalked and reniform or cordate and obscurely lobed: stamens 6 or 7. (*Cortusina*.)

B. With spine-like stipules.

14. *echinatum*, Curt. Fleshy caudex armed with persistent spine-like stipules: lvs. long-petioled, white-tomentose, cordate-ovate and obtuse, about 3-7-shallow-lobed, the lobes rounded and crenulate: peduncle long and branched; fls. white, with a spot near the center (varying to all purple), the petals notched; calyx downy, the tube several times longer than the lobes. B.M. 309. G.C. III. 46:245. J.H. III. 49:71. G.W. 15, p. 203.—Now and then advertised. The fls. are said to change color during the day; and the color may be shades of purple. It is offered in S. Calif.

BB. Without spines.

15. *odoratissimum*, Ait. (*Geranium odoratissimum*, Linn.). NUTMEG GERANIUM. Fig. 2841. Plant lax, the sts. ascending or more or less tortuose: st. or caudex very short, throwing up many slender and weak soft-pubescent branches: lvs. very long-stalked, soft, round-cordate and very obtuse, the blade 1 in. or somewhat more in length and broader, obscurely 3- or more-lobed, the margins dentate-crenate; petioles 3-4 in. long and shorter above; stipules triquetrous or broadly ovate, usually connate: peduncles long and borne opposite the lvs., 5-10-fld.; fls. pedicelled, white or whitish; calyx more or less pubescent, the spur $\frac{1}{2}$ in. or less long, the sepals or lobes lanceolate, acute, with membranaceous margins; petals twice or less longer than calyx-lobes, about $\frac{1}{2}$ in. long, linear-spatulate, rounded at apex.—

2845. *Domesticum pelargonium*. One of the Show or Lady Washington pelargoniums ($\times \frac{1}{2}$). No. 21.

Apparently a common plant., cult. for its pleasant-scented foliage. The plant known to gardeners as *P. fragrans* is either this species or a close derivative from it. Harvey refers *P. fragrans*, Willd., to *P. exstipulatum*; but Knuth separates it as follows:

16. *fragrans*, Willd. (*P. odoratissimum* × *P. exstipulatum*, Sweet. *Geranium fragrans*, Poir. *G. odoratissimum erectum*, Andr.). Plant strict, the branches more or less erect: scarcely suffruticose, the sts. more or less squarrose-branched, leafy: lf.-blade to 1 in. long and nearly as wide, obtuse-cordate, the margin crenate or crisped, pubescent, the upper lvs. sessile and the lower long-petioled; stipules triquetrous, free: fls. nearly sessile, whitish, and more or less red-veined; calyx pubescent, the spur $\frac{1}{4}$ – $\frac{1}{2}$ in. long; sepals or calyx-lobes lanceolate or ovate-lanceolate, acute; petals twice or more longer than calyx-lobes, about $\frac{1}{2}$ in. long, much narrowed at base, the apex rounded.

AAAAAA. Plant woody, not succulent, much branched, the foliage often scented but not "fishy:" lvs. various, but not pinnately parted: infl. paniculate or umbel-like; 2 upper petals longer and broader than the others, marked; good stamens 7 or 6. (*Pelargium*.)

B. Lvs. not distinctly lobed, though often angled, mostly oval or ovate and cordate (exceptions in *P. domesticum*).

17. *betulinum*, Ait. (*Geranium betulinum*, Linn.). Erect and shrubby, downy on the young growths: lvs. subglabrous, stalked, oval or ovate, obtuse or not prominently acute, rounded or truncate at base, the stipules sharp and deciduous: fls. light purple, the broad upper petals with dark streaks; petals 2–3 times longer than lanceolate sepals, nearly equal, 1 in. or more long, cuneate-obovate, rounded and entire at apex. B.M. 148.—A handsome and neat plant.

18. *cordatum*, L'Her. Figs. 2842, 2843. Shrubby and erect, villous or nearly glabrous: lvs. long-stalked, cordate-acute, denticulate and sometimes obscurely lobed; stipules with broad base but subulate, deciduous: peduncles usually branched, the pedicels and calyx soft-hairy; fls. purplish, the petals twice as long as the sepals, the two larger nearly or quite 1 in. long, cuneate-obovate, the apex rounded and entire. B.M. 165 (as *P. cordifolium*). G.M. 54:627.—Distinguished from *P. cucullatum* by its flat cordate acute lvs. It is a handsome plant in bloom. The plant in cult. as *P. cordatum*

2846. *Pelargonium quercifolium*. Leaves often more deeply lobed ($\times \frac{1}{4}$). No. 25.

(Fig. 2843), has lvs. more truncate at the base than the descriptions and old pictures call for, although on some shoots the lvs. may be typically cordate. In the wild, the plant runs into several forms, distinguished largely by pubescence.

19. *cucullatum*, Ait. (*Geranium cucullatum*, Linn.). Tall and shrubby plant, much branched, softly and densely villous: lvs. long-stalked, kidney-shaped and cupped or cucullate, denticulate, very soft-pubescent, the stipules ovate-acute and withering; fls. red or reddish, in many-fld. panicles, the pedicels and calices densely silky-hairy, the petals twice as long as the lance-acuminate

2847. Forms of leaf of *Pelargonium graveolens* ($\times \frac{1}{2}$). No. 26.

sepals, the two larger ones about 1 in. long and $\frac{1}{2}$ in. broad, rounded or retuse at apex, red with darker veins.—"Very common round Capetown and in the western districts, where it is often used as an ornamental hedge-plant."—Harvey. Known in England from 1690, and the parent, with *P. angulosum* and probably others, of the fancy or show pelargoniums of gardeners. Probably not known in cult. in its pure or original form.

20. *angulosum*, Ait. (*Geranium angulosum*, Mill.). Fig. 2844. Differs from *P. cucullatum* in its harsh-hairy covering and rigid angled lvs.: the lvs. are short-stalked, truncate or broadly cuneate at base, with 3–5 shallow angular and acute short rigid lobes: panicles with fewer-fld. umbels; pedicels and calices densely rough-hairy; petals twice as long as the acuminate sepals.—Linnaeus included this plant in his *Geranium cucullatum*, but Aiton separated it as a distinct species. Linnaeus' *cucullatum* was founded on literature. One of his sources of information was Dillenius' "Hortus Elthamensis," with a picture; but this picture, which is reduced in Fig. 2844, is what is now known as *P. angulosum*. This is one of the species which has entered largely into the pelargoniums of florists. Has been cult. since 1724.

21. *domesticum* class. COMMON, SHOW, FANCY, and LADY WASHINGTON GERANIUMS (OR PELARGONIUMS). Fig. 2845. This name distinguishes the garden type of florist's and fancy pelargonium. The race is said to be derived chiefly from *P. cucullatum*, *P. angulosum*, and *P. grandiflorum*, but the writer can see little evidence of the blood of *P. grandiflorum*. It seems to be nearest to *P. cucullatum*, having the cucullate or disk-shaped not lobed lvs. and mostly the soft-hairiness of that species. In many of them, however, the lvs. are distinctly angle-lobed, suggesting *P. angulosum*. *P. domesticum* is meant to comprise the whole range of garden forms of the Show or Lady Washington pelargoniums. The name will enable one to talk about these garden plants with precision. To many of these garden forms specific botanical names have been given, so that

P. domesticum is not the first name that has been applied in this group, but the writer is not aware that any collective or group name has been given. Sweet, in particular, has given Latin names to various forms. These old names, however, apply to particular historical forms, and it would be violence to enlarge their application to cover the entire group, and it would be difficult to choose any one of them as more applicable, under botanical rules, than others. It is probably also inaccurate to call this garden form either *P. cucullatum* or *P. angulosum*.

2848. *Pelargonium Radula*.
($\times \frac{1}{2}$)

on both surfaces; stipules ovate-acuminate, withering: fls. small, white, with red near the center, in a lax panicle, the pedicels many times longer than calyx-tube; 3 lower petals longer than sepals. B.M. 518.—Scent like peppermint, and for that reason it is somewhat grown. The sts. are long and straggly.

BBB. *Lvs. sharply 3-7-lobed and sharply toothed or serrate.*

23. *capitatum*, Ait. (*P. Drummondii*, Turcz. *Geranium capitatum*, Linn.). Sts. weak and trailing, but suffrutescent at base, with long white hairs: lvs. long-stalked, cordate, 3-5-lobed and the lobe rounded and toothed; stipules broad-cordate, pointed; peduncles longer than the lvs., densely many-fld., the fls. sessile, rose-purple, with calyx-tube much shorter than the hairy mucronate calyx-lobes. B.M. 7346.

—Plant rose-scented, but not in general cult. in its pure form; fls. in dense many-fld. heads.

24. *vitifolium*, Ait. (*Geranium vitifolium*, Linn.). Erect, more or less woody, densely hairy and villous: lvs. long-petioled, cordate at base, 3-lobed, the lobes shallow and very obtuse and rounded, dentate; stipules broad-cordate; peduncle longer than lf., simple and densely many-fld.; fls. sessile, small, purple; calyx-tube not half so long as the hairy aristate segms.; petals twice longer than sepals, 2 of them larger and purple at base and the other 3 smaller and unicolored.—Differs from *P. capitatum* in erect habit and lvs. less deeply cut.

BBBB. *Lvs. deeply several to many-lobed, with narrow divisions, rather rough or stiff, strong-scented.* ROSE GERANIUMS.

25. *quercifolium*, Ait. (*Geranium quercifolium*, Linn. f.). OAK-LEAVED GERANIUM. SCARLET-FLOWERING ROSE GERANIUM. Fig. 2846. Shrubby and branchy, somewhat hairy and glandular: lvs. with stalks 2-4 in. long, cordate-ovate in outline, with 2-3 pairs of oblong side lobes (lvs. pinnatifid), which extend nearly to the midrib and are again toothed and notched; stipules small, 2 pairs at each node (or bifid); fls. few to several, rather small, red or purplish, in umbels and with short

pedicels, the bracts laciniate; sepals elliptical and mucronate, half as long as the petals.—A rather common greenhouse plant, the lvs. often with a dark spot, and not agreeably scented.

26. *graveolens*, L'Her. (*Geranium graveolens*, Thunb.). Fig. 2847. Much like the last, but lvs. longer-petioled and palmately 5-7-lobed or parted, the broad lobes flat and pinnatifid into many mostly obtuse lobes; stipules cordate-acute: fls. many, on mostly long peduncles, pink or light purple, small, the calyx hairy and nearly sessile, the calyx-lobes half as long as the petals.—This is one of the commonest forms of rose geranium, a leafy plant with a rather heavy balsamic odor. A lf. is well depicted in Fig. 2847. There are many derivatives from it.

27. *hispidum*, Willd. (*Geranium hispidum*, Linn. f.). Woody at base but herbaceous upward, 2-3 ft., much branched, hairy and glandular: lvs. long-stalked, hispid on both surfaces, 4-5 in. across, 5-7-lobed, the lobes acuminate and unequally sharp-toothed and more or less lobulate; stipules cuspidate: fls. panicle, small, white to carmine; calyx-tube shorter than pedicels, the segms. lance-acuminate; petals about twice longer than sepals.—An old cult. plant.

28. *Rádula*, L'Her. (*P. multifidum*, Salisb. *Geranium Rádula*, Cav. *G. revolutum*, Jacq. f.). Fig. 2848. Differs from *P. graveolens* in the narrower divisions with revolute margins of the lvs.: the lvs. are deeply palmately parted, the lobes narrow linear and pinnatifid, all rough-hispid on the upper surface and soft-pubescent beneath: fls. small, pale purple, with dark streaks, the peduncles short and hispid and about 4-5-fld., fls. pedicellate; calyx-tube short, the lobes or sepals setose and glandular. B.M. 95.—Does not appear to be in the trade in a pure form, but the narrow-lyd. rose geraniums are probably hybrids between this and *P. graveolens*.

29. *denticulatum*, Jacq. (*Geranium denticulatum*, Poir.). Fig. 2849. Much like *P. Rádula*, but the lf. lobes very denticulate and flat: lvs. glabrous and viscid above, somewhat hispid beneath; stipules ovate-lanceolate: fls.

3-4, subsessile, on short hairy peduncles, lilac or rose-purple, the 2 upper petals toothed or 2-lobed and with dark streaks; calyx-tube short, the segms. or lobes oblong, mucronate and villous.—Plant weaker than *P. Rádula*. It has a balsamic odor. Perhaps it has entered into the garden forms of rose geranium. Intro. into England in 1789.

BBBBB. *Lvs. small, round-cordate, 3-lobed half their depth and the margins toothed or jagged.*

30. *crispum*, L'Her. Much branched and very scabrous or rough, shrubby, glandular: lvs. 2-ranked, small and rigid, short-stalked, cuneate, truncate or slightly cordate at base, coarsely toothed, more or less 3-lobed: fls. 2-3 on short peduncles, violet, the lower petals narrow; calyx-tube glandular and roughish, shorter than the pedicels, the lobes or sepals oblong and acuminate.—A neat strict-growing plant with lemon-scented foliage. Probably not in general cult. now in a pure form. Variable in the wild. Var. *latifolium*, Harv., Figs. 2850,

2849. *Pelargonium denticulatum*.
($\times \frac{1}{2}$)

2851, has lvs. twice the size of the type, and is a worthy plant.

31. *Limnæum*, Sweet. LEMON GERANIUM. Lvs. larger than in the last, not 2-ranked, soft: fls. purple and lilac.—A garden hybrid, *P. crispum* probably being one of its parents. There is a form with variegated lvs. Sometimes known to gardeners as *P. odoratum*. It is a neat and worthy plant, and showy when in flower. It has a lemon or balm scent. The variety known as Lady Mary is of this group.

2850. *Pelargonium crispum* var. *latifolium*. ($\times \frac{1}{4}$)

2851. *Pelargonium crispum* var. *latifolium*. A lower leaf. ($\times \frac{1}{2}$)

Any number of Latin-formed names of *Pelargonium* may appear in the trade, for the hybrids and varieties are numerous and not always readily referable to the species as forms or varieties.—*P. Blandfordianum*, Sweet (*P. graveolens* $\times$ *P. echinatum*). A good grower, shrubby, the branches roughish pubescent: lvs. flat, 7-lobed, the lower lobes deeply lobed again, all bluntly toothed, strong-scented: fls. white or pale blush, the upper petals with 2 red spots. G.M. 54:626.—*P. brevipetalum*, N. E. Br. = *P. polyccephalum*.—*P. Cotyledonis*, L'Her. Lvs. evergreen, at base of plant, cordate, 3 in. across, entire or nearly so, whitish beneath, wrinkled above: fls. on scape-like peduncles above the lvs., $\frac{1}{2}$ in. across, white. St. Helena. Requires little heat. G. 35:235.—*P. inaequilobum*, Mast. Allied to *P. multibracteatum*. Pilose: lvs. 3-lobed, the terminal lobe ovate-lanceolate and again lobed in middle, margins toothed: fls. greenish yellow with purple in base. Trop. Afr. Perhaps same as *P. Fischeri*, Engl.—*P. tuberosum*, N. E. Br. A very recent species from S. Afr.: herb with bulbous root-stock: lvs. 4 or 5, all radical, twice ternately divided, $\frac{1}{2}$ – $1\frac{1}{4}$ in. long and broad, the ultimate segms. linear: petals nearly $\frac{1}{2}$ in. long, pale yellow with 2 red lines at base.—*P. polyccephalum*, E. Mey. (*P. brevipetalum*, N. E. Br.). St. thick and fleshy, ovoid, rising very little above the ground, short-branched at top: lvs. in a rosette, bipinnately divided, ovate-oblong in outline, thick and fleshy; pinnae 5 or 6 pairs, pinnatisect: fls. pale yellow, the petals shorter than sepals. Cape Colony.—*P. roseum*, Hort., is a name of no botanical standing, applied to some of the common forms of rose geranium of the *P. Radula* group.

L. H. B.

PELECYPHORA (Greek, *hatchet-bearing*; from an alleged resemblance in the tubercles). *Cactaceæ*. HATCHET CACTUS. Two species closely allied to *Mammillaria*; sometimes seen in cactus collections.

Stems globular, short-cylindric or clavate, small, often cespitose: tubercles strongly compressed from the sides; areoles very long and narrow, bordered on each side by a row of about 20 very short, appressed comb-like spines: fr. naked.

aselliformis, Ehrb. (from a fancied resemblance to *Asellus*, the wood-louse). Juice watery: tubercles ashy green, more or less deeply grooved to the woolly axil; spines not projecting beyond the margin of areole: fls.

purple with paler sepals: fr. near the center, red. Nuevo Leon and San Luis Potosi, Mex. I.H. 5:186. Var. *concolor* has pure purple fls. B.M. 6061.

pectinata, Schum. Juice milky: tubercles bright green with naked axils; spines projecting a little beyond the margin of tubercle: fls. yellow, lateral. Oaxaca, Mex.

KATHARINE BRANDEGEE.

PELIOSÁNTHE (Greek, *livid flowers*, referring to the flowers of certain species). *Liliaceæ*. Plants with short horizontal rhizomes, long-petioled radical lvs. and fls. borne in spikes or simple racemes: perianth-tube above the ovary, short, broad, campanulate; limb spreading-rotate with 6 subequal, broad, obtuse lobes; stamens 6 with very short filaments; ovary inferior, 3-celled; stigma 3-lobed; cells with 2 ovules erect from the base, anatropous; seeds oblong or globose, fleshy. About 12 species from India, the E. Indies, and Malayan Peninsula. The following have occasionally appeared in cult: *P. Teta*, Andr. Lvs. 2-7; petiole variable in length: scape naked or with a few scales above and large membranous sheaths at the base; raceme 6-12 in.; bracts 1-3 to every fascicle of fls., pedicels short; fls. $\frac{1}{4}$ – $\frac{1}{2}$ in. diam., purplish or bluish green: seeds as large as a pea, olive-blue. Himalaya, Malaya. B.M. 1302. The var. *Mantegazziana*, Pampanini, is a form with less rigid lvs. than the type. Malaya. *P. violacea*, Wall., has the habit of *P. Teta* and fls. of the same size and color but solitary in the bracts: seeds $\frac{1}{2}$ in. long, oblong. Himalaya, Burma. Var. *Clarkei*, Baker, differs from the type in having more conspicuous transverse nervules and a darker purple fl. Assam and Malaya. B.M. 8276. Cult. in botanic gardens in the tropical house.

F. TRACY HUBBARD.

PELLÆA (Greek, *pellos*, dusky; from the usually dark-colored leaf-stalks). *Polypodiaceæ*. Small rock-loving ferns thriving best on limestone rocks.

Sori at the ends of free veins forming a mostly continuous marginal band around the segms. and covered by the more or less changed margin of the segms. The species are perhaps 40 or more, widely scattered in many countries. Some of them are glasshouse subjects and others are hardy.

A. Lvs. simply pinnate.

B. Lfts. 4-5 pairs.

Pringlei, Dav. Lvs. with 4-5 pairs of large triangular hastate stalked lfts. 1 in. or more across either way: sori forming a wide marginal band. Mex.

BB. Lfts. 5-8 pairs.

Bridgesii, Hook. (*Platyloma Bridgesii*, J. Smith). Lfts. subsessile, orbicular or subcordate, 4-5 lines long: sori confluent in a broad intramarginal band. Calif.

BBB. Lfts. 20-40.

rotundifolia, Hook. Fig. 2852. Lfts. mostly short-stalked, oblong or roundish, entire, obtuse. New Zeal.

falcata, Fée (*Platyloma falcatum*, J. Smith). Lfts. nearly sessile, lanceolate or lanceolate-oblong, mucronate and often slightly falcate: sori in broad lines. India to Austral. and New Zeal.

2852. *Pellaea rotundifolia*. ($\times \frac{1}{4}$)

AA. Lvs. bipinnate.

B. Pinnæ formed of 3 sessile lfts.

ternifolia, Link. Lvs. 6-12 in. long on strong dark chestnut stalks, narrow, with 6-12 opposite pairs of pinnæ; lfts. closely rolled together, linear. Trop. Amer.

BB. Pinnæ (at least the lower ones) of more than 3 lfts.

mucronata, Eaton (*P. Wrightiana*, Hook.). Lvs. 3-6 in. long, 1-3 in. wide, deltoid; pinnæ with several linear-oblong pinnules on each side $\frac{1}{4}$ in. long, with inrolled edges and a sharp mucronate point. Texas to Calif.

atropurpurea, Link. Lvs. 4-12 in. long, 2-6 in. wide, lanceolate to ovate-lanceolate, with several pinnules which are sessile, auricled or heart-shaped at the base, the broad line of sporangia nearly hiding the narrow marginal indusium. E. Amer., to the Rocky Mts.

2853. *Pellaea viridis*. A good greenhouse fern, likely to be known to gardeners as *P. hastata*.

AAA. Lvs. at least tripinnatifid.

B. The lvs. triangular-deltoid, with narrow ultimate divisions.

densa, Hook. CLIFF BRAKE. Lvs. 2-3 in. long, 1-1 $\frac{1}{2}$ in. wide, on slender brown stalks; segms. linear with inrolled edges sharp-pointed; indusium permanently covering the sori. Pacific N. Amer., and eastward to Wyo.

BB. The lvs. elongate, ovate, or lanceolate.

andromedæfolia, Fée. Lvs. 6-12 in. long, 3-6 in. wide; ultimate divisions 1 $\frac{1}{2}$ -2 lines long, linear-oblong, with inrolled edges. Calif.—Sometimes known as the coffee fern.

viridis, Prantl (*P. hastata*, Link). Fig. 2853. Lvs. 6-24 in. long, 6-12 in. wide; ultimate divisions ovate or lanceolate, 1-2 in. long, nearly sessile; sori in a narrow marginal line. E. and S. Afr. Small lvs. are sometimes only bipinnate. Very commonly used in small ferneries.

P. Stelleri, Beddome (*P. gracilis*, Hook.), a rare membranous species of the eastern states, is more closely allied to the genus *Cryptogramma*, to which Prantl has referred it.

L. M. UNDERWOOD.

PELLIÖNIA (J. Alphonse Pellion, officer in Freycinet's voyage around the world).. *Urticaceæ*. Two choice tender creeping foliage plants of this genus are cultivated, suitable for baskets and for the borders of greenhouses under the benches.

Herbs, often creepers, rarely subshrubs from Trop. and E. Asia and the Pacific Isls.: lvs. alternate, 2-ranked, unequal at the base, entire or serrate: fls. monœcious or dioecious, mostly in dense cymes; perianth-segms. 5, rarely 4, in fr. sometimes unchanged but usually increased and investing the fr. —Species 15-20. The cult. species require warm temperature and moist atmosphere. Prop. by cuttings and division. One of the species was once advertised as a *Peperomia*.

Daveauana, N. E. Br. Prostrate, 1-2 ft. long, the sts. succulent and creeping below, the tips pubescent: lvs. 1-2 $\frac{1}{2}$ in. long, sessile, obliquely oblong or orbicular, crenate and obtuse at tip, dark bronzy olive-green more or less flushed violet or red, with a fern-like figure of light green down the middle of the lf., the figure being narrowly oblong and crenate. This figure is sometimes absent from some of the lvs. The lvs. are more acuminate than in the next. Burma to Cochin-China. R.H. 1880:290 (as *Begonia Daveauana*, a charming picture). I.H. 29:472.

pulchra, N. E. Br. Practically glabrous, with creeping fleshy sts. tinged purplish: lvs. obliquely oblong and very obtuse, dull blackish along the midrib and veins, the inter-spaces being light green, the under surface pale purplish. Cochin-China. I.H. 30:479. A.G. 15:4.

WILHELM MILLER.
L. H. B.†

PELORIA (Greek for *monster*). A term applied to the phenomenon when usually irregular flowers, such as those with some of the petals or sepals spurred or saccate, develop all the parts of each set alike, thus becoming radially symmetrical. The case was observed by Linnæus in *Linaria vulgaris*, Fig. 2854, and the term peloria was given by him. Flowers often become peloric on account of changes in their relations to light, but other causes certainly contribute. A reverse change, by which radial flowers become zygomorphic, occurs in many *Compositæ* when the corollas of disk-florets become strap-shaped, as in the cultivated asters and chrysanthemums. Sometimes, on the contrary, all spurs fail to develop

2854. Toad-flax—*Linaria*. Showing normal flowers above and an abnormal or peloric flower beneath.

2855. Normal columbine flower. with spurs present.

(Figs. 2855, 2856.) Peloric forms have been of little significance in horticulture. See Keeble, Pellew and Jones on inheritance of peloria in foxgloves, "New Phytologist," Vol. IX, page 68 (1910).

PELTÁNDRA (Greek, referring to the peltate anthers). *Araceæ*. ARROW ARUM. Stemless herbs, being excellent subaquatic plants, their large thick sagittate leaves always adding variety and interest to margins of ponds and to bog-gardens.

Leaves glossy, arrow-shaped, arising from strong underground parts: fls. monœcious and naked, the staminate ones on the upper part of the long spadix, the anthers sessile and imbedded and opening by terminal pores, the 1-loculed ovaries attended by 4 or 5 scale-like bodies or staminodia: spathe usually exceeding the spadix: fr. a 1-3-seeded, mostly leathery berry, borne in large globose clusters.

—Two species in E. Amer. which have been much confused. Single specimens or clumps are usually most prized. Peltandras are easy to colonize.

virginica, Kunth (*P. undulata*, Raf.). Lvs. narrow-sagittate, the basal lobes long and nearly or quite acute: spathe 4-8 in. long, green, convolute around the spadix for its whole length; sterile part of the spadix much longer than the pistillate part: fr. green, 1-3-seeded. In shallow pools or bog margins, New England to Fla. and west. A.G. 14:111.—The root is composed of thick cords or fibers.

sagittæfolia, Morong (*P. alba*, Raf.). Lvs. broader the basal lobes short: spathe white, the upper part expanded and calla-like; sterile part of spadix little, if any, longer than pistillate part: fr. red, 1-seeded. Va., south.—Root tuberous.

L. H. B.

PELTÀRIA (Greek, *small shield*, referring to the roundish form of the pod). *Cruciferae*. Tall glabrous herbs with entire cauline lvs., sagittate-cordate at base: fls. white, subcorymbose; fruiting pedicels spreading or recurved, filiform, without bracts; sepals broad; stamens free, not toothed: silique orbiculate or obovate, 1-celled, indehiscent, much compressed, reticulate. About 4 species, natives of S. Eu., Asia Minor, Syria, and Persia. *P. alliacea*, Jacq. About 1 ft. high, with entire petals, smooth flat pods, and sagittate-clasping lvs. This species has the odor of garlic, as its name would suggest. E. Eu. Offered in the trade as a cut-fl. R.H. 1908, p. 131.

PELTIPHÝLLUM: *Saxifraga*.

PELTÓPHORUM (Greek, *shield and bearing*, referring to the peculiar stigma). *Leguminosæ*. A few species of splendid tropical trees, belonging to the same tribe as the gorgeous Poinciana and Cæsalpinia.

Flowers yellow; petals 5, roundish; stamens 10, free, declinate; filaments pilose at base; ovary sessile, 2- to many-ovuled: pod flattish, indehiscent, with narrowly winged margins. Peltophorum is distinguished from

2856. Peloria.—Lack of spurs in the columbine. (Compare Fig. 2855.)

Cæsalpinia and Poinciana by the valvate calyx-segms. of the latter, while the two former have their calyx-segms. strongly imbricated. The peculiar stigma of Peltophorum readily distinguishes it from its close allies, Cæsalpinia and Hæmatoxylon (logwood). These genera represent a type of structure widely different from the northern pea-shaped fls., as they have 5 distinct petals which are all about the same size and shape. There is a fine colored plate of a Peltophorum in Blanco's "Flora of the Philippines," where the golden fls. are nearly $1\frac{1}{2}$ in. across, a dozen of them in each raceme, and 4 racemes uniting to form a great panicle. Peltophorums have the Mimosa type of foliage. Each lf. of *P. inerme* has 8-10 pairs of pinnæ, and each pinna 10-20 pairs of lifts. The generic name is preoccupied by Peltophorus, a genus of grasses, and is consequently replaced by some recent authors by the name Baryxylum.

A. Lifts. $\frac{1}{2}$ - $\frac{3}{4}$ in. long, 10-20-pinnate.

inérmé, Naves (*Cæsalpinia inermis*, Roxbg. *P. ferrugineum*, Benth. *Baryxylum inermé*, Pierre). Tree, attaining 100 ft., taking its specific name from the dense rusty tomentum which covers the young branches, petioles, and infl.: lvs. 8-10-pinnate, oblong, obtuse or retuse, oblique at the base, $\frac{1}{2}$ - $\frac{3}{4}$ in. long, shining above, rusty tomentose beneath: racemes 5-6 in. long, in a large terminal panicle; calyx about $\frac{3}{8}$ in. long; petals obovate, undulate, villous at the base: pod 3-4 in. long, $\frac{3}{4}$ -1 in. wide, 1-3-seeded. Austral., Philippines.—Intro. at Santa Barbara, Calif., by Franceschi, but has not been a success there.

AA. Lifts. $\frac{1}{4}$ - $\frac{1}{2}$ in. long, 20-30-pinnate.

dùbium, Taub. (*Cæsalpinia dubia*, Spreng. *P. Vogelianum*, Walp. *Baryxylum dubium*, Pierre). A large beautiful tree with rusty tomentose branches, petioles, and infl.: lvs. 9-18 in. long, 12-20-pinnate, 2-4 in. broad; lifts. 20-30-pinnate, oblique, oblong, obtuse, symmetrical or base unequal, $\frac{1}{4}$ - $\frac{1}{2}$ in. long, minutely rusty tomentose beneath, becoming glabrate: infl. a broad terminal panicle; fls. in simple or branched racemes; pedicels $\frac{1}{4}$ - $\frac{1}{2}$ in. long; calyx-tube very short, turbinate; petals broadly obovate, $\frac{1}{2}$ - $\frac{3}{4}$ in. long, margin wrinkled; very short-stalked, rusty tomentose: pod 3 in. long, $\frac{3}{4}$ in. broad, acute at both ends, 2-seeded. Brazil.

P. L. RICKER.

PENIOCÈREUS (Latin combination, meaning *phal-loid Cereus*). *Cactaceæ*. Low slender erect plants, growing from very large fleshy turnip-shaped roots: sts. usually 4- or 5-ribbed: fls. large, nocturnal, usually white: fr. ovoid, long-acuminate, bright scarlet, edible.

Gréggii, Brit. & Rose (*Cereus Gréggii*, Engelm.). Slender, branching, 2-3 ft. high, $\frac{3}{4}$ -1 in. diam., from an extraordinarily large tuberous root (often 6-10 in. long and 4-6 in. diam.): ribs 3-6, acute; spines subulate from bulbous base, very short and sharp, 7-11, 1 or 2 being central: fls. white or yellowish, 6-8 in. long: fr. ovate, alternate at base and apex, bright scarlet, fleshy and edible, 1-2 in. long. Borders of Texas, New Mex., Ariz., and southward.

J. N. ROSE.

PENNISETUM (Latin, *penna*, feather; *seta*, bristle). *Graminææ*. Mostly stout grasses with bristly spike-like inflorescence, making conspicuous border and lawn plants.

Spikelets as in Panicum, but surrounded by several bristles that fall with the spikelet.—Species about 40 in tropical regions, one species cult. for fodder, some of the others for ornament.

The plummy grass known to gardeners as *P. longistylum* is much used for bedding. It is, perhaps, the finest dwarf grass which is grown chiefly for its flower parts. It sometimes survives the winter at Washington, D. C., but should always be treated as a tender

subject. Plants raised every year from seed are satisfactory if seed is sown early enough, but divisions of old plants will give larger pieces which flower sooner and require less attention than seedlings. The old plants may be wintered anywhere out of reach of frost. About February 1, in the latitude of Washington (a month later North), cut off the old leaves to within 6 inches of the crowns; divide the clumps into small pieces, trim the roots so that they will ultimately go into 3- or 4-inch pots, and place the pieces thickly together in boxes of sandy soil in a greenhouse with a temperature of about 60°. As soon as new roots have started, pot the young plants. They may be removed to a coldframe long before the soft bedding material demands all the available indoor space. (G. W. Oliver.)

A. Annual: bristles about as long as the spikelet.

americanum, Schum. (*Penicillaria spicata*, Willd. *Pennisetum typhoideum*, Rich.). PEARL MILLET. Culm 3-8 ft., pubescent below the spike; lvs. long and broad: spike cylindrical, 3-10 in. long, $\frac{3}{4}$ in. thick, the globose grain bursting through its lemma and palea. Native country unknown.—Occasionally grown in the southern states, where it ripens seed. May be grown farther north for forage. A luxuriant annual, long cult. in the Old World for forage and more or less for the grain which is used as food.

AA. Perennials: bristles much exceeding the spikelet.

B. Bristles plumose.

villosum, Brown (*P. longistylum* of florists, not of Hochst.). Fig. 2857. Spike broad, 2-4 in. long, and feathery from the bearded bristles; culm 1-2 ft. high, pubescent below the spike. Abyssinia. R.H. 1890, p. 489.

Rüppelii, Steud. (*P. Rüppelianum* of some works). Fig. 2858. Culms taller and spikes 6-10 in., longer and

more graceful than the preceding. Abyssinia. R.H. 1897, pp. 54, 55. I.H. 42, p. 206. G.W. 1:363.—The form most frequently cult. has a pale roseate spike. This is sold under the names *P. atrosanguineum*, *P. hybridum Henkelianum*, or CRIMSON FOUNTAIN GRASS. G.W. 13:255. R.B. 36, p. 58.—A half-hardy form with

2858. *Pennisetum Rüppelii*.

dark purplish foliage and purplish crimson spikes has recently been intro. under the name of *P. cupreum*. It does not reproduce reliably from seed.

BB. Bristles naked.

c. Spikes several on each main culm, borne on short branches; one bristle in each cluster much longer than the others.

latifolium, Spreng. (*Gymnathrix latifolia*, Schult.). Culm 3-4 ft., bearing several nodding spikes 1-2 in. long; lvs. lanceolate, $\frac{1}{2}$ in. broad. Argentina. R.H. 1890, p. 546. G.W. 3, p. 424; 6, p. 113.

cc. Spikes single, terminating each main culm; bristles more or less equal.

japonicum, Trin. (*P. compressum*, R. Br. *Gymnathrix japonica*, Kunth). Culm 2-3 ft., scabrous, especially under the dense cylindrical 2-3-in.-long spike: blades long and narrow. China.

macrothrix, Trin. (*Gymnathrix caudata*, Schrad.). Culms tall, bearing a slender spike as much as a foot long. S. Afr.

macrostachyum, Trin. (*Gymnathrix macrostachys*, Brongn.). Culms 4-5 ft., blades broad, flat; spike 8-12 in., resembling that of *P. Rüppelii*. E. Indies.—A half-hardy form with dark purplish foliage and handsome dark crimson spikes has recently been intro. under the name of *P. macrophyllum atropurpureum*. M.D.G. 1906:9. Does not reproduce reliably from seed.

nervosum, Trin. Tall branching perennial with tawny or purplish compact spikes is offered by a western nursery. S. Amer. A. S. HITCHCOCK.

PENNYROYAL of Europe, *Mentha Pulegium*; of America, *Hedeoma pulegioides*. Bastard P., or blue curls, is *Trichostema dichotomum*. All are members of the mint family.

The garden pennyroyal, *Mentha Pulegium*, is a European perennial, used for seasoning. It is one of the

2857. *Pennisetum villosum*.

HH. Infl. very open and loose, due to the fact that the peduncles are 3-6 in. long and the pedicels 1 in. or more long and the fls. drooping.

25. *rotundifolius*, Gray. Fig. 2863. About 2 ft. tall, branching from the base, glaucous: lower lvs. thick and leathery, orbicular-ovate and obtuse, long-petioled, st.-lvs. sessile and cordate-orbicular: fls. 1-1½ in. long, narrow-tubular, yellow-red, the lobes short and acute; sterile filament glabrous. N. Mex. B.M. 7055. G.C. III. 4:265. G.F. 1:473 (reduced in Fig. 2863).

GG. Lvs. serrate or dentate.

H. Sterile filament bearded at the tip or along one side (Nos. 26-32).

I. Color of fls. purple, blue or rose, sometimes ranging to white.

26. *campanulatus*, Willd. Branching from the base, 2 ft. or less tall: lvs. lanceolate or the upper ones ovate-lanceolate, long-acuminate, broad at the base and sessile, strongly serrate: infl. long and narrow, the peduncles usually 2-fld.; fls. 1 in. long, rose-purple or violet (sometimes white in cult.), the corolla funnelliform, the lobes rounded and spreading and the lower lip broader than the upper, the sterile filament hairy at the top. Mex. and Guatemala. B.M. 3884.—An old garden plant which is variable in color and which has received many names, as *P. angustifolius*, *P. atropurpureus*, *P. roseus*. See B.R. 1122. L.B.C. 15:1429, 1438. G.C. III. 50:93 (a white form). *P. pulchellus*, Lindl., by some referred here, is by others kept distinct, differing in corolla abruptly ventricose or swollen above, violet or lilac with white veins, the lips nearly equal, throat spotted and villous, sterile filament bearded at end. Mex. B.R. 1138.

27. *humilis*, Nutt. Low, usually not over 6 in. tall, pubescent in the infl.: lvs. oblong to lanceolate, somewhat glaucous, the upper ones small-toothed: infl. 3-4 in. long, with 2-5-fld. peduncles; fls. ½ in. long, rather narrow, deep blue or sometimes ranging to white, the lower lip bearded within. Rocky Mts., west. F. 1875:241.

28. *gracilis*, Nutt. Taller, sometimes minutely puberulent, slender: lvs. linear-lanceolate, sometimes nearly entire, the radical ones spatulate or oblong: infl. strict, the peduncles 2- or more-fld.; fls. nearly 1 in. long, mostly narrow-funnelform, lilac-purple ranging to white. Neb. to Colo. and northward, on moist prairies. B.M. 2945. L.B.C. 16:1541.—A pretty species.

II. Color of fls. nearly or quite white, but sometimes shaded with red or purple.

29. *tubiflorus*, Nutt. St. 2-3 ft., erect, not leafy above: lvs. oblong to ovate-lanceolate, barely serrulate, passing into small bracts above: infl.

of densely-fld., somewhat whorled clusters; fls. about ¾ in. long, scarcely 2-lipped, the spreading limb nearly as long as the tube, white or nearly so and sometimes tinged with purple. Mo., Kans., and Ark.

30. *laevigatus*, Soland. (*Chelone Pentstemon*, Linn.). Tall and slender, 2-4 ft., more or less glaucous: lvs. rather firm, purplish, somewhat glossy, ovate to ovate-oblong-lanceolate and clasping, the radical ones oblanceolate or broader, all small-toothed: infl. long and loose; fls. about 1 in. long, white and sometimes tinged with color, rather slender, narrow at the base, the short lobes not wide-spreading, the small lower lip bearded at the base. Pa., west and south. B.M. 1425.—A common plant, best known in the following form.

Var. *Digitalis*, Gray (*P. Digitalis*, Nutt. *Chelone Digitalis*, Sweet). Very tall, 4-5 ft., with larger white abruptly inflated fls. B.M. 2587.—Sometimes becomes a weed in old fields, from Maine south and west, but probably not indigenous in all this range. It is in cult., as a border plant. By some authors kept distinct as a species. *P. Smálili*, Heller, is a handsome allied species from N. C. and Tenn., with bright pink-purple gibbous corolla, pubescent or puberulent sts.: root-lvs. oval or ovate; st.-lvs. lanceolate or ovate-lanceolate, smooth both sides, serrate.

31. *Pálmeri*, Gray. Plant 2-3 ft. tall, the foliage glaucous: lvs. thick, ovate to oblong-lanceolate, the lower petioled and the upper connate, very sharp-dentate or sometimes almost entire: infl. long, mostly glandular; fls. cream-white tinted with pink, the narrow part of the tube about as long as the calyx, the upper part very wide and open, the mouth ¾ in. across and 2-lipped; sterile filament yellow-bearded. Utah, south and west. B.M. 6064. F.S. 20:2094. F. 1874:37.

III. Color of fls. red.

32. *Clèvelandii*, Gray. Two ft. or above, more or less glaucous, becoming woody at the base: lvs. rigid, oblong or ovate, sharp-toothed, the upper ones usually connate by their bases: infl. long and narrow; fls. ¾ in. long, crimson, with narrow throat; sterile filament bearded at top. S. Calif. and Low. Calif. G.M. 36:626. F. 1878, p. 149.

HH. Sterile filament glabrous.

33. *deustus*, Douglas. Sts. 1 ft. or less tall, from a woody base, glabrous throughout: lvs. thickish, varying from nearly linear to lanceolate to ovate, some or all of them serrate, the uppermost sessile: infl. many-fld., loose and open; fls. not over ½ in. long, dull white or yellowish white and sometimes tinged with purple, wide-mouthed, the lobes wide-spreading. Mont. and Wyo. to Calif. B.R. 1318.

34. *spectabilis*, Thurb. Two to 4 ft., erect, somewhat glaucous: lvs. ovate to ovate-lanceolate or sometimes oblong, acute, the upper ones acuminate and connate by their bases, very sharp serrate-dentate: infl. long and many-fld.; fl. 1 in. or more long, rose-purple or lilac, the narrow part of the tube about twice the length of the calyx, the upper part broad and full, the lobes rounded. New Mex. to S. Calif. B.M. 5260.—A beautiful species.

EE. St. and lvs. more or less pubescent or hirsute.

F. Corolla 2 in. long.

35. *Cobæa*, Nutt. Fig. 2864. Straight and erect, stout, about 2 ft., minutely pubescent: lvs. thick, ovate-oblong to oblong to broad-lanceolate, the upper ones clasping: infl. mostly simple and open; fls. very large, reddish purple to white, the base very narrow but the upper part of the fl. broad and open, the limb only obscurely 2-lipped; sterile filament bearded. Prairies, Mo. and Neb., south. B.M. 3465. Gn. 49:406. G. 29:83. F.S.R.2, p. 271. Mn. 4:113.—Very showy, and probably one of the parents of the garden race of hybrid pentstemons (see No. 13).

2863. *Pentstemon rotundifolius*. (× ½)

FF. Corolla 1 in. or less long.

36. *erianthera*, Pursh (*P. cristatus*, Nutt.). Only a few inches high, pubescent, usually viscid above: lvs. linear-lanceolate to narrow-oblong: infl. erect, leafy below; fls. about 1 in. long, purplish, rather abruptly dilated above, the lower lip bearded; sterile filament strongly yellow-bearded. Dakota to Colo., north and west.—Good.

37. *ovatus*, Douglas. St. slender but erect, 2-4 ft., more or less pubescent: lvs. ovate, rather thin, bright green, serrate, the upper ones clasping: infl. erect but lax, the peduncles 2- to several-fld.; fls. about $\frac{2}{3}$ in. long, blue changing to purple, 2-lipped and the lower lip bearded. Idaho, west and north. B.M. 2903.—Good.

38. *hirsutus*, Willd. (*P. pubescens*, Soland. *Chelone hirsuta*, Linn.). Loose-growing, the slender often decumbent sts. reaching 2 ft., usually viscid-pubescent: lvs. oblong to narrow-lanceolate, small-toothed, the radical ones ovate to spatulate: infl. loose and open, the peduncles 2-3 in. long and the pedicels often 1 in. long; fls. about 1 in. long, drooping, dull purple or violet or varying to flesh-color, rather narrow, with 2 short lobes densely bearded on the palate; sterile filament densely bearded. Dry fields and banks from Maine and Ont. to Fla. and Texas. B.M. 1424. G.M. 56:493.—The common pentstemon of the E., and useful in cult. *P. Mackayanus*, Knowles & Westc., is perhaps distinct: corolla often shorter, sparingly bearded in throat, purple: upper st.-lvs. with dilated or rounded bases rather than narrow-lanceolate. Ala. to Ark.

AA. Cells of anthers not dehiscing or opening to the base, the basal part remaining saccate

B. Lvs. dentate or serrate.

C. Plant viscid and soft-pubescent.

39. *glandulosus*, Douglas (*P. staticifolius*, Lindl.). Rather stout, 2-3 ft. tall: lvs. rather thin, ovate-lanceolate, acuminate, the upper ones clasping, the radical ovate or oblong, all toothed or serrate: infl. narrow, leafy below, the peduncles few- to several-fld.; fls. large, somewhat over 1 in. long, lilac, with inflated throat, the lips short and broad; sterile filament glabrous. Idaho to Wash. and Ore. B.M. 3688. B.R. 1262; 1770.—Showy.

CC. Plant not viscid, either glabrous or puberulent.

40. *venustus*, Douglas. St. erect, nearly simple, leafy, 2 ft. or less tall, glabrous: lvs. thickish, oblong-lanceolate to ovate-lanceolate, very sharply serrate: infl. narrow, not leafy, the peduncles 1-3-fld.; fls. usually more than 1 in. long, somewhat 2-lipped, light purple, somewhat hairy within; sterile filament hairy above. Idaho, Ore., and Wash. B.R. 1309.

41. *diffusus*, Douglas (*P. argutus*, Paxt.). Sts. about 2 ft. tall, diffuse: lvs. ovate to oblong-lanceolate to cordate-ovate, unevenly and deeply serrate: infl. leafy, the pedicels very short; fls. $\frac{3}{4}$ in. long, light purple, 2-lipped; sterile filament hairy above. Ore., north. B.M. 3645. B.R. 1132. R.H. 1872:410.

BB. Lvs. deep-cut.

42. *Richardsonii*, Douglas. Rather loosely branching: lvs. ovate-lanceolate to narrow-lanceolate, deeply cut or pinnatifid, the upper ones not opposite: infl. loose; fls. $\frac{3}{4}$ in. long, light purple; sterile filament somewhat hairy at top. Ore. and Wash. B.M. 3391. B.R. 1121. L.B.C. 17:1641.

BBB. Lvs. entire.

C. Sterile filament somewhat bearded.

43. *gracilentus*, Gray. A foot or more tall from a woody base, naked above: lvs. lanceolate to linear or oblong, glabrous: infl. loose, the viscid peduncles 2-5-fld.; fls. $\frac{1}{2}$ in. long, violet-blue; the lobes very short. N. Calif., Nev., and Ore.

CC. Sterile filament glabrous.

44. *latus*, Gray. About 1 ft. tall, from a woody base, closely pubescent: lvs. lanceolate to linear-lanceolate, the radical ones spatulate: fls. 1 in. long, blue. Calif. and Nev.

45. *Roëzlii*, Regel. Smaller than the last, 1 ft. or less, glabrous or minutely puberulent below: lvs. lanceolate, linear, or oblanceolate: fls. pale blue or violet, on divergent branches, the corolla $\frac{1}{2}$ - $\frac{2}{3}$ in. long. Nev., Calif., Ore.—The plant cult. under this name may be, in some cases, *P. azureus* var. *Jaffrayanus*.

46. *azureus*, Benth. Erect or ascending, 3 ft. or less, glaucous, sometimes minutely pubescent: lvs. narrow-ovate to narrow-lanceolate: infl. loose and open; fls. $1\frac{1}{2}$ in. or less long, blue to violet, sometimes reddish at the base, the limb about 1 in. across. Calif. B.M. 7504. J.F. 2:211.

Var. *Jaffrayanus*, Gray (*P. Jaffrayanus*, Hook.). Lower (about 1 ft. tall), young sts. tinged with red: lvs. oblong to oval or the upper ones ovate-lanceolate, glaucous: fls. large and showy, rich blue and reddish at base and in the throat. Calif. B.M. 5045. R.H. 1874:430. H. F.II. 1:5. G.C. III. 58:67.—By some kept specifically distinct.

47. *heterophyllus*, Lindl. Sts. reaching 3-5 ft., from a woody base, the plant mostly green: lvs. varying from oblong-lanceolate above to lanceolate and linear below: infl. loose and open, the peduncles usually 1- or 2-fld.; fls. about 1 in. long, pink or rose-purple, very slender at the base but full or inflated above, the lips well marked. Calif. B.R. 1899. B.M. 3853. R.H. 1875:110; 1896, p. 348; 1901:164.

48. *Bridgesii*, Gray. Sts. 1-2 ft., from a somewhat woody base, glabrous or perhaps puberulent up to the thyse: lvs. lanceolate to linear: peduncles 1-5-fld., short, glandular; corolla about 1 in. long, bright scarlet, narrow, the lips one-third length of tube; anthers sagittate. S. W. Colo. and N. Ariz. to Calif. Gn. 66, p. 348.

As the pentstemons are mostly attractive plants, any number of them may appear in the lists of distributors of native plants. *P. baecharifolius*, Hook. Glabrous or only obscurely puberulent, leafy at base, 2 ft.: lvs. oblong, sharp-toothed, sessile: fls. deep carmine-red, on 1-3-fld. peduncles; corolla 1 in. long, broadly tubular, with short 2-lipped limb; sterile filament naked. Texas. J.F. 3:227.—*P. pygmaeus* is a name listed abroad: "very compact-growing; pale purple and white fls."—*P. virgatus*, Gray. Glabrous or slightly glandular, the st. strict and long: lvs. linear-lanceolate: fls. lilac with purple veins, in $\frac{1}{2}$ virgate thyse; corolla $\frac{1}{4}$ in. long, with a wide throat and distinctly 2-lipped. New Mex., Ariz.

L. H. B.

PEONY: *Paeonia*.

PEPEROMIA (Greek, pepper-like). *Piperaceæ*. An enormous genus of tropical and subtropical herbs, including a few small but choice foliage plants for warmhouse, conservatory, or house decoration.

Annual, or perennial by a creeping caudex or by

2864. *Pentstemon Cobaea*. ($\times \frac{1}{4}$)

HH. Infl. very open and loose, due to the fact that the peduncles are 3-6 in. long and the pedicels 1 in. or more long and the fls. drooping.

25. *rotundifolius*, Gray. Fig. 2863. About 2 ft. tall, branching from the base, glaucous: lower lvs. thick and leathery, orbicular-ovate and obtuse, long-petioled, st.-lvs. sessile and cordate-orbicular: fls. 1-1½ in. long, narrow-tubular, yellow-red, the lobes short and acute; sterile filament glabrous. N. Mex. B.M. 7055. G.C. III. 4:265. G.F. 1:473 (reduced in Fig. 2863).

GG. Lvs. serrate or dentate.

H. Sterile filament bearded at the tip or along one side (Nos. 26-32).

I. Color of fls. purple, blue or rose, sometimes ranging to white.

26. *campanulatus*, Willd. Branching from the base, 2 ft. or less tall: lvs. lanceolate or the upper ones ovate-lanceolate, long-acuminate, broad at the base and sessile, strongly serrate: infl. long and narrow, the peduncles usually 2-fld.; fls. 1 in. long, rose-purple or violet (sometimes white in cult.), the corolla funnel-form, the lobes rounded and spreading and the lower lip broader than the upper, the sterile filament hairy at the top. Mex. and Guatemala. B.M. 3884.—An old garden plant which is variable in color and which has received many names, as *P. angustifolius*, *P. atropurpureus*, *P. roseus*. See B.R. 1122. L.B.C. 15:1429, 1438. G.C. III. 50:93 (a white form). *P. pulchellus*, Lindl., by some referred here, is by others kept distinct, differing in corolla abruptly ventricose or swollen above, violet or lilac with white veins, the lips nearly equal, throat spotted and villous, sterile filament bearded at end. Mex. B.R. 1138.

27. *humilis*, Nutt. Low, usually not over 6 in. tall, pubescent in the infl.: lvs. oblong to lanceolate, somewhat glaucous, the upper ones small-toothed: infl. 3-4 in. long, with 2-5-fld. peduncles; fls. ½ in. long, rather narrow, deep blue or sometimes ranging to white, the lower lip bearded within. Rocky Mts., west. F. 1875:241.

28. *gracilis*, Nutt. Taller, sometimes minutely puberulent, slender: lvs. linear-lanceolate, sometimes nearly entire, the radical ones spatulate or oblong: infl. strict, the peduncles 2- or more-fld.; fls. nearly 1 in. long, mostly narrow-funnel-form, lilac-purple ranging to white. Neb. to Colo. and northward, on moist prairies. B.M. 2945. L.B.C. 16:1541.—A pretty species.

II. Color of fls. nearly or quite white, but sometimes shaded with red or purple.

29. *tubiflorus*, Nutt. St. 2-3 ft., erect, not leafy above: lvs. oblong to ovate-lanceolate, barely serrulate, passing into small bracts above: infl.

of densely-fld., somewhat whorled clusters; fls. about ¾ in. long, scarcely 2-lipped, the spreading limb nearly as long as the tube, white or nearly so and sometimes tinged with purple. Mo., Kans., and Ark.

30. *laevigatus*, Soland. (*Chelone Pentstemon*, Linn.). Tall and slender, 2-4 ft., more or less glaucous: lvs. rather firm, purplish, somewhat glossy, ovate to ovate-oblong-lanceolate and clasping, the radical ones oblanceolate or broader, all small-toothed: infl. long and loose; fls. about 1 in. long, white and sometimes tinged with color, rather slender, narrow at the base, the short lobes not wide-spreading, the small lower lip bearded at the base. Pa., west and south. B.M. 1425.—A common plant, best known in the following form.

Var. *Digitalis*, Gray (*P. Digitalis*, Nutt. *Chelone Digitalis*, Sweet). Very tall, 4-5 ft., with larger white abruptly inflated fls. B.M. 2587.—Sometimes becomes a weed in old fields, from Maine south and west, but probably not indigenous in all this range. It is in cult., as a border plant. By some authors kept distinct as a species. *P. Smálili*, Heller, is a handsome allied species from N. C. and Tenn., with bright pink-purple gibbous corolla, pubescent or puberulent sts.: root-lvs. oval or ovate; st.-lvs. lanceolate or ovate-lanceolate, smooth both sides, serrate.

31. *Pálmeri*, Gray. Plant 2-3 ft. tall, the foliage glaucous: lvs. thick, ovate to oblong-lanceolate, the lower petioled and the upper connate, very sharp-dentate or sometimes almost entire: infl. long, mostly glandular; fls. cream-white tinted with pink, the narrow part of the tube about as long as the calyx, the upper part very wide and open, the mouth ¾ in. across and 2-lipped; sterile filament yellow-bearded. Utah, south and west. B.M. 6064. F.S. 20:2094. F. 1874:37.

III. Color of fls. red.

32. *Clêvelandii*, Gray. Two ft. or above, more or less glaucous, becoming woody at the base: lvs. rigid, oblong or ovate, sharp-toothed, the upper ones usually connate by their bases: infl. long and narrow; fls. ¾ in. long, crimson, with narrow throat; sterile filament bearded at top. S. Calif. and Low. Calif. G.M. 36:626. F. 1878, p. 149.

HH. Sterile filament glabrous.

33. *deustus*, Douglas. Sts. 1 ft. or less tall, from a woody base, glabrous throughout: lvs. thickish, varying from nearly linear to lanceolate to ovate, some or all of them serrate, the uppermost sessile: infl. many-fld., loose and open; fls. not over ½ in. long, dull white or yellowish white and sometimes tinged with purple, wide-mouthed, the lobes wide-spreading. Mont. and Wyo. to Calif. B.R. 1318.

34. *spectabilis*, Thurb. Two to 4 ft., erect, somewhat glaucous: lvs. ovate to ovate-lanceolate or sometimes oblong, acute, the upper ones acuminate and connate by their bases, very sharp serrate-dentate: infl. long and many-fld.; fl. 1 in. or more long, rose-purple or lilac, the narrow part of the tube about twice the length of the calyx, the upper part broad and full, the lobes rounded. New Mex. to S. Calif. B.M. 5260.—A beautiful species.

EE. St. and lvs. more or less pubescent or hirsute.

F. Corolla 2 in. long.

35. *Cobæa*, Nutt. Fig. 2864. Straight and erect, stout, about 2 ft., minutely pubescent: lvs. thick, ovate-oblong to oblong to broad-lanceolate, the upper ones clasping: infl. mostly simple and open; fls. very large, reddish purple to white, the base very narrow but the upper part of the fl. broad and open, the limb only obscurely 2-lipped; sterile filament bearded. Prairies, Mo. and Neb., south. B.M. 3465. Gn. 49:406. G. 29:83. F.S.R.2, p. 271. Mn. 4:113.—Very showy, and probably one of the parents of the garden race of hybrid pentstemons (see No. 13).

2863. *Pentstemon rotundifolius*. (× ½)

FF. Corolla 1 in. or less long.

36. *erianthera*, Pursh (*P. cristatus*, Nutt.). Only a few inches high, pubescent, usually viscid above; lvs. linear-lanceolate to narrow-oblong; infl. erect, leafy below; fls. about 1 in. long, purplish, rather abruptly dilated above, the lower lip bearded; sterile filament strongly yellow-bearded. Dakota to Colo., north and west.—Good.

37. *ovatus*, Douglas. St. slender but erect, 2-4 ft., more or less pubescent: lvs. ovate, rather thin, bright green, serrate, the upper ones clasping; infl. erect but lax, the peduncles 2- to several-fld.; fls. about $\frac{3}{4}$ in. long, blue changing to purple, 2-lipped and the lower lip bearded. Idaho, west and north. B.M. 2903.—Good.

38. *hirsutus*, Willd. (*P. pubescens*, Soland. *Chelone hirsuta*, Linn.). Loose-growing, the slender often decumbent sts. reaching 2 ft., usually viscid-pubescent: lvs. oblong to narrow-lanceolate, small-toothed, the radical ones ovate to spatulate; infl. loose and open, the peduncles 2-3 in. long and the pedicels often 1 in. long; fls. about 1 in. long, drooping, dull purple or violet or varying to flesh-color, rather narrow, with 2 short lobes densely bearded on the palate; sterile filament densely bearded. Dry fields and banks from Maine and Ont. to Fla. and Texas. B.M. 1424. G.M. 56:493.—The common pentstemon of the E., and useful in cult. *P. Mackayanus*, Knowles & Westc., is perhaps distinct: corolla often shorter, sparingly bearded in throat, purple; upper st.-lvs. with dilated or rounded bases rather than narrow-lanceolate. Ala. to Ark.

AA. Cells of anthers not dehiscing or opening to the base, the basal part remaining saccate

B. Lvs. dentate or serrate.

C. Plant viscid and soft-pubescent.

39. *glandulosus*, Douglas (*P. staticifolius*, Lindl.). Rather stout, 2-3 ft. tall: lvs. rather thin, ovate-lanceolate, acuminate, the upper ones clasping, the radical ovate or oblong, all toothed or serrate; infl. narrow, leafy below, the peduncles few- to several-fld.; fls. large, somewhat over 1 in. long, lilac, with inflated throat, the lips short and broad; sterile filament glabrous. Idaho to Wash. and Ore. B.M. 3688. B.R. 1262; 1770.—Showy.

CC. Plant not viscid, either glabrous or puberulent.

40. *venustus*, Douglas. St. erect, nearly simple, leafy, 2 ft. or less tall, glabrous: lvs. thickish, oblong-lanceolate to ovate-lanceolate, very sharply serrate; infl. narrow, not leafy, the peduncles 1-3-fld.; fls. usually more than 1 in. long, somewhat 2-lipped, light purple, somewhat hairy within; sterile filament hairy above. Idaho, Ore., and Wash. B.R. 1309.

41. *diffusus*, Douglas (*P. argutus*, Paxt.). Sts. about 2 ft. tall, diffuse: lvs. ovate to oblong-lanceolate to cordate-ovate, unevenly and deeply serrate; infl. leafy, the pedicels very short; fls. $\frac{3}{4}$ in. long, light purple, 2-lipped; sterile filament hairy above. Ore., north. B.M. 3645. B.R. 1132. R.H. 1872:410.

BB. Lvs. deep-cut.

42. *Richardsonii*, Douglas. Rather loosely branching: lvs. ovate-lanceolate to narrow-lanceolate, deeply cut or pinnatifid, the upper ones not opposite; infl. loose; fls. $\frac{3}{4}$ in. long, light purple; sterile filament somewhat hairy at top. Ore. and Wash. B.M. 3391. B.R. 1121. L.B.C. 17:1641.

BBB. Lvs. entire.

C. Sterile filament somewhat bearded.

43. *gracilentus*, Gray. A foot or more tall from a woody base, naked above: lvs. lanceolate to linear or oblong, glabrous: infl. loose, the viscid peduncles 2-5-fld.; fls. $\frac{1}{2}$ in. long, violet-blue; the lobes very short. N. Calif., Nev., and Ore.

CC. Sterile filament glabrous.

44. *lætus*, Gray. About 1 ft. tall, from a woody base, closely pubescent: lvs. lanceolate to linear-lanceolate, the radical ones spatulate; fls. 1 in. long, blue. Calif. and Nev.

45. *Roëzlii*, Regel. Smaller than the last, 1 ft. or less, glabrous or minutely puberulent below: lvs. lanceolate, linear, or oblanceolate; fls. pale blue or violet, on divergent branches, the corolla $\frac{1}{2}$ - $\frac{2}{3}$ in. long. Nev., Calif., Ore.—The plant cult. under this name may be, in some cases, *P. azureus* var. *Jaffrayanus*.

46. *azureus*, Benth. Erect or ascending, 3 ft. or less, glaucous, sometimes minutely pubescent: lvs. narrow-ovate to narrow-lanceolate; infl. loose and open; fls. $1\frac{1}{2}$ in. or less long, blue to violet, sometimes reddish at the base, the limb about 1 in. across. Calif. B.M. 7504. J.F. 2:211.

Var. *Jaffrayanus*, Gray (*P. Jaffrayanus*, Hook.). Lower (about 1 ft. tall), young sts. tinged with red: lvs. oblong to oval or the upper ones ovate-lanceolate, glaucous: fls. large and showy, rich blue and reddish at base and in the throat. Calif. B.M. 5045. R.H. 1874:430. H. F.II. 1:5. G.C. III. 58:67.—By some kept specifically distinct.

47. *heterophyllus*, Lindl. Sts. reaching 3-5 ft., from a woody base, the plant mostly green: lvs. varying from oblong-lanceolate above to lanceolate and linear below; infl. loose and open, the peduncles usually 1- or 2-fld.; fls. about 1 in. long, pink or rose-purple, very slender at the base but full or inflated above, the lips well marked. Calif. B.R. 1899. B.M. 3853. R.H. 1875:110; 1896, p. 348; 1901:164.

48. *Bridgesii*, Gray. Sts. 1-2 ft., from a somewhat woody base, glabrous or perhaps puberulent up to the thyrse: lvs. lanceolate to linear: peduncles 1-5-fld., short, glandular; corolla about 1 in. long, bright scarlet, narrow, the lips one-third length of tube; anthers sagittate. S. W. Colo. and N. Ariz. to Calif. Gn. 66, p. 348.

As the pentstemons are mostly attractive plants, any number of them may appear in the lists of distributors of native plants. *P. baccharifolius*, Hook. Glabrous or only obscurely puberulent, leafy at base, 2 ft.: lvs. oblong, sharp-toothed, sessile; fls. deep carmine-red, on 1-3-fld. peduncles; corolla 1 in. long, broadly tubular, with short 2-lipped limb; sterile filament naked. Texas. J.F. 3:227.—*P. pygmaeus* is a name listed abroad: "very compact-growing; pale purple and white fls."—*P. virgatus*, Gray. Glabrous or slightly glandular, the st. strict and long: lvs. linear-lanceolate; fls. lilac with purple veins, in σ virgate thyrse; corolla $\frac{3}{4}$ in. long, with a wide throat and distinctly 2-lipped. New Mex., Ariz.

L. H. B.

PEONY: *Paeonia*.

PEPEROMIA (Greek, *pepper-like*). *Piperaceæ*. An enormous genus of tropical and subtropical herbs, including a few small but choice foliage plants for warmhouse, conservatory, or house decoration.

Annual, or perennial by a creeping caudex or by

2864. *Pentstemon Cobaea*. ($\times \frac{1}{4}$)

tubers formed at the base: sts. prostrate, creeping and thread-like, or erect and slender, or short thick, and succulent: lvs. alternate, opposite, or in whorls of 3-4 (rarely 5-6), entire, fleshy or membranous, often with pellucid dots, sometimes attractively veined or colored: fls. minute, usually disposed in a dense spike; stamens 2; anther-cells confluent; stigma sessile, undivided, often tufted: fr. a small or minute berry, 1-seeded, with thin pericarp.

2865. *Peperomia Sandersii*, usually known as *P. arifolia* var. *argyreia*.

of many kinds is uncertain, while great numbers are monocarpic, that is, they flower and fruit once and then die. In the following account, the names are those that mostly appear in the trade and in horticultural literature; how far these names may be properly determined botanically is a subject for investigation.

Peperomias are very attractive and beautiful small-stature glasshouse plants, having particularly a very decorative appearance among other foliage plants. For their general culture they need a warm house. By the end of January they will become active both in root and foliage. From February on they will stand an increase in temperature to about 62° at night; this may be increased until they are having 65° to 70° with an increase of 10° to 15° on bright days. As the sun gets powerful in the spring, they will need shade, or as soon as the foliage shows signs of losing color. In the summer they need a good supply of water, but in autumn and winter they require very careful watering. In spring and summer they profit by frequent light spraying. Keep the atmosphere of the house in a moist state, but avoid a stuffy or stagnant condition. In the slow time of winter, they will stand the temperature to be lowered to about 60° with 10° to 15° increase with sun. Give less spraying and be very careful in giving water during the dark and dull time, otherwise the roots will rot.—They can be propagated readily from pieces of the stems or leaves placed in pans of silver sand and plunged where they will have bottom heat of 75° to 80°. Do not cover with glass as it tends to make them rot. Keep shaded and be very careful about watering, and they will soon root. When they make sufficient roots, they may be potted up into small pots, using loam four parts, fibrous peat two parts, and enough sand to keep it open. For larger shifts, use a more lumpy mixture of fibrous loam, fibrous peat, and well-decayed cow-manure. By July or August they should get their last shift, until the coming of spring. They will stand full sun by the end of September and through the winter, and this greatly aids in keeping them in good condition at that season. (J. J. M. Farrell.)

A. Plants for pots or pans, erect-habited.

B. Lvs. alternate.

C. Sts. short or wanting.

Sandersii, A. DC. (*P. arifolia*, Hort., not Miq.). Fig. 2865. Stemless: lvs. alternate, peltate, 5 x 3½ in.,

rounded at base; petioles dark red, 4-8 in. long. Cult. only in the form var. *argyreia*, Hook. f., which differs from the type in having broad, parallel longitudinal bands of white between the nerves. Brazil. B.M. 5634. F.S. 23:2438. G. 25:197. A.G. 19:17. F.R. 1:637.—This plant seems to be the commonest in cult. here, under the name of *P. arifolia* var. *argyreia*. However, Casimir DeCandolle thought that this plant is not the true *P. arifolia*, and he renamed it *P. Sandersii* (after Wilson Sanders), but the name is often spelled *Saundersii* in trade catalogues. The distinctions which DeCandolle makes are technical. The evident ones are that *P. arifolia* has a short st. and catkins much longer than the lvs., while *P. Sandersii* has no st. and the catkins are about as long as the lvs.

Versaffeltii, Lem. Distinguished from *P. marmorata*, which it much resembles, by the lvs. being alternate, by the basal lobes, which do not overlap but are separated by a notch as in a typical cordate lf. A smaller and more delicate but more branched plant: st. short: st., branches, petioles, and peduncles much longer, translucent, and pale rose (not green): lvs. heart-shaped at base. Upper Amazon, Brazil. I.H. 16:598.

tithymaloides, A. Dietr. (*P. magnoliæfolia*, A. Dietr.). Lvs. alternate, subovate, acutish, narrowed at base, 2-3 in. long, base acute, more than 9-nerved; nerves subopposite; petiole 1 in. long, keeled beneath: st. rooting below. Santo Domingo.—Monocarpic (annual or biennial.)

maculôsa, A. Dietr. Lvs. alternate(?), ovate-lanceolate, bright shining green, very fleshy; petioles beautifully spotted with purple. Santo Domingo.—A good subject for a pan. Perennial.

cc. Sts. numerous, long, slender.

metállica, Lind. & Rod., is distinct from all others here described by its numerous slender unbranched sts. 12-16 in. high, and lanceolate lvs. It probably belongs in some other genus or family. It was intro. in 1892 before the fls. were known and its exact botanical position determined. Lvs. blackish green, painted white down the middle, red-veined below; petioles short, reddish brown. Peru. I.H. 39:157. G.W. 3, p. 160.

bb. Lvs. opposite or in whorls.

marmorata, Hook. St. short, much-branched, nearly ½ in. thick: lvs. opposite, ovate-cordate, deeply 2-lobed at the base, the lobes rounded and overlapping. The lvs. are 3-5 x 1½-2¾ in., not so broad as *P. Sandersii*, and less concave. Not advertised, but has been unnecessarily confused with *P. Sandersii*.

latifolia, Miq. St. 10 in. high, decumbent: lvs. obovate or obtusely ovate, 5-7-nerved, opposite or in whorls of 3, base acute, glabrous above, pubescent beneath; petiole 7-8 lines long. Hawaii.—Monocarpic (annual or biennial).

aa. Plants for hanging-baskets, drooping.

nummularifolia, HBK. Delicate creeper, with long, thread-like, rooting sts. and small orbicular lvs., puberulous or glabrate: lvs. alternate, ciliate; obscurely palmately 3-nerved, 3-4 lines diam. Trop. Amer.—The above description is from Grisebach. Five other species in the W. Indies have the same habit. *P. prostrata*, Hort., is probably a synonym. It is a stove basket-plant figured in G.C. II. 11:717 and F. 1881, p. 103, with a good-sized petiole. The lvs. are very small for the genus, and are said not to exceed ½ in. Lvs. bordered and nerved with greenish white. Annual. Nicholson refers *P. prostrata* to *P. brevipes*, and keeps *P. nummularifolia* separate. *P. brevipes*, C. DC., has lvs. alternate, orbiculate, younger ones hirsute, older ones glabrate, ciliate, 1-nerved: style none: berry with a very short stipe. Trop. Amer.

In some collections is a plant known as *P. crassifolia* (which is probably not *P. crassifolia*, Baker, of Trop. Afr.). It is a very distinct species with dark green, ovate, fleshy lvs. 3×5 in., becoming very hard when old; sts. branched and upright in habit, a foot in height; fls. in insignificant catkins. It is a very good plant and deserves to be more generally known.—*P. pubifolia*, Veitch. Perennial creeper of unknown habitat, suitable for hanging-baskets. Lvs. small, ovate, marked with a central gray bar.—*P. resediflora*, André, intro. in 1865, was "found in all stoves" 2 years later and said to be "a plant for the million." It differs from all the above in being a flowering plant rather than a foliage plant, for the lvs. are merely bordered lighter green and the fls. are about as showy as those of a mignonette, each one 3-4 lines long, and 100 or so in a raceme. St. 1-1½ ft. high, red, forked; lvs. broadly ovate, cordate. Colombia. B.M. 6619.

WILHELM MILLER.
L. H. B.†

PEPŌNIA (Greek, *melon*, *gourd*). *Cucurbitaceæ*. Climbing or sprawling plants, little known in horticulture.

Perennial herbs, prostrate or scandent, often villous, with fibrous roots: lvs. lobed or rarely entire, dentate: fls. large, yellow or whitish, monœcious, the males solitary or racemose; corolla-lobes 5, obovate; stamens 3; female fls. solitary: fr. large or medium, fleshy, oblong or cylindrical; seeds many, black, flattened.—Species about a dozen in Trop. and S. Afr. Because of an earlier genus of the same name, Engler has proposed the name *Peponium* for this group.

Mackénnii, Naudin. Lvs. broadly ovate-cordate, 5-lobed to the middle: male fls. solitary; calyx-tube subglabrous, narrowed from apex to base. It is hardly scandent, densely villous and the st. grows ½-6 ft. long: lvs. 4 in. long; petals over 1 in. long; fr. oblong-ovoid, about the size of a hen's egg, green at first, then marbled with white, finally all red; pulp orange-colored, insipid. Natal.—Once intro. in S. Calif., but now apparently lost; probably not of much value as an ornamental.

L. H. B.

PEPPER. With American horticulturists "pepper" usually means the red pepper (*Capsicum*, which see) of which the green pepper is merely the unripe stage. The black and white pepper of commerce are treated under *Piper*.

The red pepper (*Capsicum*) is doubtless native of the New World, as there is no record of its having been known prior to the discovery of America. According to Irving's "Life of Columbus," this plant was first mentioned by Martyr in 1493, who says Columbus brought home "pepper more pungent than that from Caucasus," evidently comparing it with the black pepper of commerce from the oriental countries. It was cultivated by the natives in tropical and southern America before this time, and about a century later Gerarde speaks of its being brought into European gardens from Africa and southern Asia. The ease with which the plant spreads in warm latitudes, together with the increased commercial trade immediately following the discovery of America, doubtless caused a rapid dissemination through tropical Asia and Africa, where it was supposed by many to be indigenous and from there introduced into European gardens.

The first record of the use of pepper is apparently by Chauca, physician to the fleet of Columbus, who in 1494 alludes to it as a condiment. Writers about a century later considered it valuable as an aid to digestion and also mentioned its use in dressing meats, dyeing, and other purposes. Medicinally it was much used for various ailments, such as dropsy, colic, ague, and toothache, and when mixed with honey and applied externally was used as a remedy for quinsy. At a later date preparations were given for black vomit and various tropical fevers, and for a tonic, also for gout, paralysis and other diseases. Its modern use is largely as a condiment, forming a seasoning in almost every dish eaten by the inhabitants of warm countries. The smaller varieties are mostly used for this purpose. The cayenne pepper of commerce consists of the small pungent fruits reduced to a powder. The unground

fruit is also made into pepper sauce of various brands by preserving in brine or strong vinegar. The Tabasco variety furnishes the well-known Tabasco pepper sauce and Tabasco catsup. "Chilli con carne" consists of the small pungent varieties finely ground and mixed with meat. These hot varieties are often eaten raw by native Mexicans, as are radishes, and also form an important ingredient of tamales so common in that country and fairly well known in the southern United States. The large thick-fleshed sweet varieties are desired more by persons farther north, who use them in various ways, served like tomatoes in either ripe or green state, with vinegar and salt, or made into mangoes by cutting one side, removing seeds and filling with chow-chow pickles. The parts are then tied together, placed in jars with vinegar and kept until wanted. The fruit is often used in stuffing pitted olives after being cooked in olive oil. In Spain some are canned after being thus cooked and eaten with French salad dressing.

Paprika is a well-known Hungarian and Spanish condiment made from the long, and more or less pointed type of peppers. The Spanish paprika is much milder in flavor than the Hungarian, it being made from a less pungent pepper and doubtless in its preparation more of the seeds and placentæ are removed, which process makes a milder condiment. The seed of peppers is more or less used as a bird food; and the plants of some varieties, like Little Gem and Celestial, are grown more especially for ornamental purposes.

Some thirty varieties are recorded by American seedsmen. They differ from one another mainly in the form and pungency of fruit and habit of growth. There are endless forms among peppers, but certain types are

2866. Pepper.—The Ruby King variety.

well fixed, as indicated by the botanical varieties under *Capsicum*. Pungency is to be found in all peppers and while located in the placentæ, other parts may acquire it by contact. Most of the smaller sorts, like Coral Gem, Tabasco, Chilli, Cayenne, and Cherry contain more of the pungent properties than the large kinds, like Ruby King (Fig. 2866), Squash, Bell, Sweet Mountain, and Golden Queen. Some medium-sized varieties,

like Long Red, Celestial, and Oxheart, are hot; others, like County Fair and Kaleidoscope, are mild.

Peppers are classed as one of the minor vegetables in that they have not been grown in large quantities in any one locality and the aggregate production is smaller than the so-called truck crops, such as tomatoes, cucumbers, and the like. Most gardens near large cities in the central and southern states have been growing a few to supply the local markets. During the last decade there has been a decided increase in acreage. The census report for 1900 gives no report of production of peppers, but for 1910 there were recorded for the United States, 1,641 farms containing 3,483 acres, valued at \$408,741, an average of \$117.47 an acre. Four states with the largest acreage are:

	No. of farms	Acres	Aver. area a farm	Value	Aver. value an acre
New Jersey.....	822	1,882	2.29	\$149,433	\$79 40
California.....	55	417	7.56	52,294	124 92
Florida.....	143	296	2.07	94,246	318 40
New Mexico.....	266	260	0.97	17,228	66 26

This record ignores quantities of less than an acre with the evident exception of New Mexico, which averages .03 less than 1 acre to a farm.

It is estimated that approximately 4,000,000 pounds of paprika were imported each year during the last three or four years. The United States Department of Agriculture has demonstrated that this product can be profitably produced in the South, but if the consumption is limited to the above figure the acreage must continue to be very limited.

In growing peppers, the seed is usually planted under glass in February or March, and the young plants transplanted to pots or boxes when of sufficient size to handle. From twelve to twenty days are required for the seed to germinate, the time varying according to the age of the seed and the manner in which it has been kept. Its germinating power is said to last four years, and if kept in pods until sown will grow when six or seven years old. A light warm soil, heavily charged with humus and one that will not quickly dry out, appears to be the best. In May or June, or after all danger of frost is past, the plants (Fig. 2867) are set in the field in rows about 2½ feet apart and 18 inches apart in the rows.

2867. Pepper plant ready to transplant to the field.

The ground is kept thoroughly cultivated, not only to keep down weeds but to maintain an even but not excessive moisture at all times, which is very essential for best results in growing this plant. By keeping the soil well worked up around the plants, they stand up much better against the winds and weight of their own fruit. Pruning or pinching the tip ends after the fruit begins to mature is occasionally recommended, but is rarely practised except when specimens of especially fine fruit are desired, in which case the fruit is thinned, leaving only a few on each plant of the larger sorts. In gathering, the fruit should not be torn off but cut with a knife or scissors, leaving at least 1 inch of stem. The usual vegetable crate is used for packing and marketing the crop.

Insects rarely injure peppers growing in the field. The pepper weevil (*Anthonomus eugenii*) has done some damage to crops in the South. It is said to be easily

kept in control by gathering and destroying infested pods. Tomato-worm, bollworm, white-fly and Colorado potato-beetle sometimes attack the plant, but seldom do noticeable injury. Red-spider and green-fly (aphis) frequently attack plants growing under glass. The red-spider may be kept in check by repeatedly syringing with water, and the green-fly may be killed by fumigating with tobacco dust. Two fungous diseases frequently occur on the large varieties growing outdoors. One is a pink anthracnose (*Glaeosporium piperatum*), which causes the fruit to rot about the time it begins to ripen; the other is a dark anthracnose (*Colletotrichum nigrum*).

In preparing peppers for table use, handle them with gloves to prevent burning the fingers. Neither soap nor water will soothe hands burned by peppers, but milk will.

H. C. IRISH.

PEPPER-GRASS: *Lepidium*.

PEPPERMINT: *Mentha*. P. Stringy-bark: *Eucalyptus piperita*.

PEPPER-ROOT: *Dentaria diphylla*.

PERAPHYLLUM (from Greek, *pera*, excessively, and *phylon*; alluding to the crowded lvs.). *Rosaceæ*, subfam. *Pomeæ*. A much-branched rigid shrub, with deciduous alternate rather small and narrow partly fascicled lvs., white fls. similar to apple-blossoms in few-fl. upright umbels appearing with the lvs., and berry-like edible fr. Hardy as far north as Mass., but seems to possess only little ornamental value. It is of very slow growth and blooms only when rather old. It grows in well-drained soil and in sunny position, and is best suited to be planted on rocky slopes of southern aspect. Prop. by seeds and layers and by grafting on amelanchier or crataegus. It is closely allied to *Amelanchier*, but distinguished by its nearly umbellate fls., cylindric calyx-tube, the perfectly inferior ovary, and also by its narrow lvs. The only species is *P. ramosissimum*, Nutt., a rigid shrub, 2-6 ft. high: lvs. oblong to oblanceolate, almost sessile, entire or sparingly serrulate, silky pubescent when young, ¾-2 in. long: fls. in few-fl. erect umbel-like racemes, white or slightly tinged pink, with rose-colored disk, ¼ in. across; petals obovate, spreading; styles 2-3, free; ovary 2- or incompletely 4-celled: fr. pendulous, globose, yellow with brownish cheek, about ½ in. across. May. Ore. to Calif. and Colo. B.M. 7420.

ALFRED REHDER.

PERENNIALS tend to live from year to year, as opposed to annuals and biennials, which die root and branch after flowering and fruiting. Annuals live only one year, biennials two years. Perennials include trees, shrubs and herbs, the two former being woody, the latter not. "Perennials," as commonly used by gardeners, is a convenient shortening of the phrase "hardy herbaceous perennials," which includes peony, phlox and other non-woody plants whose roots live over the winter while their tops may die to the ground. The phrase "hardy herbaceous perennials" is also shortened in common speech to "herbaceous plants;" or one speaks of the "hardy border." See *Herbs and Border*; also *Annuals* and *Biennials*.

A popular fallacy about perennials lies in the common statement that "they die down every year and come up again in the spring." Many of them never come up after two or three years of flowering; that is, perennials are not necessarily perpetual. Peonies may be as long-lived as shrubbery, and a clump of fraxinella has been known to outlive father, son, and grandson in the same spot. But these are exceptions. The general practice with perennials is to divide them every second or third year. Nearly all hardy herbaceous plants should be lifted now and then, because the crowns that give the flowers in most desirable kinds flower only two or three seasons and then die; but the plant may be continually spreading and making new growths, which

LXXXVII. A branch of *Pereskia aculeata*, one of the leaf-bearing cacti.

furnish the flowers, and, unless lifted and divided, the stocks become scattering and unattractive. Another very good reason for lifting and dividing the perennials is that, being mostly strong-rooted plants, they deplete the soil; when shifted, they are likely to be set in a new place.

PERÉSKIA (named for Nicolas Claude Fabry de Peiresc). Also written *Peirescia*, *Peireskia*, and *Perescia*. *Cactaceæ*. Shrubs or clambering vines, grown for ornament and also for the edible fruit.

Spines in the axils in the lvs.: lvs. alternate, broad and flat, resembling those of ordinary flowering plants: fls. wheel-shaped, more or less clustered; ovary naked or leafy: fr. juicy, sometimes edible; seeds black, thin-shelled.—Some 40 names have been given in *Pereskia* for species in this and related genera, but only 13 are now recognized. Only two species are very common in collections, although *P. cubensis*, *P. amapola*, and the true *P. Bleo* have recently been intro.

aculeata, Mill. (*Cactus Pereskia*, Linn. *Pereskia fetans*, Speg.). **LEMON VINE. BLADE APPLE. BARBADOS GOOSEBERRY.** Branches woody, clambering, 10–20 ft. long: lvs. flat, lanceolate, 2–3 in. long, 1–2 in. broad: spines on old wood in clusters and straight, 1–2 in. long, on young branches 2, short and curved: fls. pale yellow with pink varieties, 1–1½ in. broad: fr. lemon-colored, the size of an olive, in age smooth. Widely spread in Trop. Amer. B.M. 7147. B.R. 1928. G.C. III. 20:625.—This species is much used as stock on which to graft other species of cacti. Var. *Godseffiana*, Hort. Lvs. richly colored, when young crimson, yellow and green above. G.C. III. 43:257 (note).

grandifolia, Haw. (*P. Bleo* of authors, not *Cactus Bleo*, HBK.). Usually tall shrubs, but sometimes growing as half clambering: lvs. often large, some 5 in. long: spines form large clusters on the old wood, usually solitary on young branches, straight: fls. in small clusters, purple, 1½–2 in. broad: fr. 2 in. long, pear-shaped. Brought, and now grown in many warm countries. B.M. 3478. G.C. III. 20:427.

P. subulata, and *P. spathulata* are to be excluded from *Pereskia*. Schumann in his Monograph of the *Cactaceæ* referred them to the genus *Opuntia*, but they more properly belong to the genus *Pereskopsis*, Brit. & Rose, which see. J. N. ROSE.

PERESKIÓPSIS (like *Pereskia*). *Cactaceæ*. *Opuntia*-like plants grown for ornament and curiosity.

Trees and shrubs: sts. and branches cylindrical: lvs. large, flat, and persistent: areoles bearing spines and glochids: fr. usually red; seeds covered with matted hairs. This genus, lately segregated from *Opuntia*, where recent writers have placed it, is very different from *Opuntia* in many ways, and resembles more closely in habit and foliage the genus *Pereskia*, although it is very different in fr. and seeds from that genus.—Eleven species have been recognized, of which 9 are now grown in Washington and in the New York Botanical Garden, although none is known in the trade.

velutina, Rose. Sts. weak, forming compact bushes: branches soft, velvety: lvs. broadly ovate: fls. yellow. Mex.

subulata, Brit. & Rose (*Pereskia subulata*, Muehl.). St. 2 ft. or less high, below half wood, above fleshy and branching: lvs. persisting a few years, dark green, shiny, as thick as a pencil, about 3 in. long, half-cylindrical and ending in a spine: areoles felted, in the young plant with a few hair-bristles, later with 2–4 straight, pale yellow spines 3–4 in. long. Mex.—Can be used as stock for epiphyllum.

spathulata, Brit. & Rose (*Pereskia spathulata*, Otto). St. upright, with few horizontal, spatulate, shiny green lvs.: the diffuse areoles at first somewhat woolly, later felted, above with a bunch of short bristles, below with 1–2 yellowish white, straight spines. Mex.

J. N. ROSE.

PERFUMERY-GARDENING. The growing of plants commercially as a source for perfume-making.

The perfumes of the market are derived in part from animal secretions (musk, civet), in part from artificial chemical compounds, and in part, and chiefly, from the class of vegetable products loosely called essential oils. "Synthetic" or chemical perfumery materials are the more or less perfect artificial reproductions of organic compounds used in perfumery. If it were possible in all cases and with perfect success to compound these substances, the production of floral perfumes would soon be at an end, as the chemical process would be sure to be cheaper than the horticultural. But nature knows how to add some touches which the chemist's art cannot imitate, and even when synthetic manufacture is possible, the result is in general regarded as a cheaper substitute. At the same time, sentimental reasons count considerably in favor of the natural perfume, and considering, further, that some perfumes cannot well be imitated chemically, there is no present cause to apprehend the extinction, or, in view of increasing demand, even the decline, of the industry of producing natural perfumery oils.

The essential oils used in perfumery are secreted in different parts of the plant. The flowers are naturally thought of first, being the seat of the fragrance of the rose, violet, cassie, jasmine, tuberose, the orange in part, and numberless other plants whose perfume is extracted or only enjoyed as naturally exhaled. The oil of lavender is yielded more by the green parts of the flower-head than by the corollas. In rose geranium, thyme, wintergreen, and patchouli the foliage is the fragrant part. A number of essences are derived from woods, as those of sandalwood, red cedar, and rhodium. The oil of sweet birch comes partly from the wood, but mainly from the inner bark, and the same is true of sassafras. In the case of the latter, however, the roots only are used; in the case of the former, the young tops. Several herbaceous roots also furnish oils, as orris-root, Canada snakeroot, and sweet flag. The rinds of the orange and other citrous fruits contain important perfumery oils, and the oil of bitter almonds comes from the fermented kernel of the nut.

The standard methods of extracting essential oils are four, namely, the use of mechanical means (chiefly expression), distillation, *enfleurage* or inflowering, and maceration. Expression appears to be applied only to the rinds of the citrous fruits. These are placed under pressure in a screw press, or sections turned wrong side out are squeezed in the fingers, the oil being taken up with a sponge, or the fruit is rubbed in a cup lined with spikes (*écuelle à piquer*), the oil collecting in a hollow handle. An *écuelle* on a larger scale in the shape of a hollow drum has also been used.

In distillation, the oil-bearing material is heated with water or subjected to hot steam, and the oil, being volatile, passes off with the steam. The oil would be lost if the vapor were not condensed, and this is accomplished by passing it through a coil or equivalent arrangement of pipe kept cool by a flow of water. The condensed steam and oil fall into a "Florentine recipient," a vessel with a spout coming out at the base but rising to the level of the top, so that the heavier liquid, sometimes oil, sometimes water, alone will enter it and can be poured off separately. After the water and oil have mainly separated, the water will still contain enough oil to make it highly fragrant, and in this state it goes to market as rose-water, orange-flower water, and the like, or is returned to the still to be redistilled with the next charge.

The remaining two methods depend on the fact that grease has the power of absorbing essential oils. In *enfleurage* the grease, without heating, is spread over both surfaces of panes of glass which are set in frames (*châssis*), so that they can be piled one over another with spaces between. In these spaces are placed the

flowers, the charge being renewed daily until the grease is sufficiently impregnated, when it constitutes a "pomade." "Extracts" are made by digesting the pomade in alcohol, which has a still stronger attraction for the perfume than has the grease. The alcohol must first be deodorized, to save perverting the floral perfume, and is then known as "Cologne spirit." The grease used in this and the next process, moreover, must be freed from all corruptible matter by a special process. Tallow and lard, commonly mixed, and sometimes the fat of the deer and other animals, are employed.

In maceration, the pomade is produced by immersing repeated charges of the flowers in melted grease or fine olive oil.

In recent times, various chemical processes for extracting perfumery have been tried, apparently with some practical success; but they have not yet supplanted the old methods. Carbon bisulfid and petroleum ether are among the solvents employed. These methods would be less easily practised by beginners and amateurs than the ordinary ones.

The art of distilling is not only not difficult to learn, but is already in practice in this country in the case of peppermint, sweet birch, sassafras, eucalyptus, and the like. More care and better apparatus would be required for distilling roses and other flowers, but the process is essentially the same. Nor do the grease processes involve any difficulties which may not be overcome by the application of a little American ingenuity and capital. In fact, the production of the raw materials of perfumery might proceed almost at once, so far as the difficulty of the processes is concerned. But can we grow the requisite plants?

That many of the standard perfumery plants will grow in this country needs no proof, and there is no reason to doubt that their fragrance in properly chosen localities will equal that of the same plants in the European centers. In general, success in this line must be looked for only southward, even in dealing with hardy plants, though there may be exceptions to this rule. Cool trade-winds and fogs at flowering time are to be shunned. The natural conditions in Florida and large parts of the other Gulf states seem not very different from those of the south of France, the great center of perfumery-farming in Europe, and in fact the feasibility of successful perfumery-farming in Florida has been demonstrated by actual trial. California has also been the scene of experiments, some of them seeming to promise success as soon as economic conditions admit. A large territory between these two points is available for some lines of the industry.

Among the particular plants to be noticed, the citrous fruits deserve a leading place. Nearly or quite all of the trees of this group, including the sweet, the bitter or Seville, and the bergamot oranges, the sweet and sour limes, the lemon, the citron, and the shaddock, contain valuable perfumes either in the peel of their fruit, or in their flowers, or in their leaves, or in more than one of these. Of the fruit-oils, that of lemon is imported into this country in largest quantity, followed by oil of bergamot, oil of orange—bitter and sweet, oil of limes and "cedrat" or citron oil, the last two in very small quantities, but the cedrat at a very high price. These oils are extracted by expression, the distilled being inferior, though it is asserted that when the "rag," or inner soft layer, is removed, the distilled oil equals the other. The oil of the bitter orange is superior to that of the sweet; the oil of bergamot is far more valuable than either, but can rarely be had in an unadulterated state. The flowers of the orange treated by distillation yield "neroli." The scent of neroli, however, is not that of the flowers, an alteration taking place during the distillation. Orange-flower water, consisting of the condensed vapor of water with a little unchanged oil adhering, affords the true odor of the

flowers. By maceration, likewise, the true floral fragrance is obtained. The abortive flowers which fall from the trees are available for perfumery use, but the flowers are also sometimes picked, presumably with a better result. Besides the product of fruit and flowers, the leaves and young twigs pruned from the sweet and bitter oranges yield to distillation the oil of "petit grain," of considerable though minor value. There is no reason to doubt the perfumery capacity of American orange groves. Indeed it has been asserted that the orange flowers of Louisiana excel in sweetness those of foreign parts. In Los Angeles, California, something has been done toward utilizing the peel, and in Florida a beginning has been made with both peel and flowers, but for the most part these resources are at present suffered to go to waste.

The lemon verbena, *Lippia citriodora* (Fig. 2868), may be mentioned in passing as furnishing an attractive perfume of the citrous order, and as available at least in Florida and California.

The perfumery products of the rose and its allies merit next attention. The value of the importation of attar of roses—to say nothing of rose perfume in other forms—exceeds that of any single citrous perfume, and at the same time the capacity of this country for producing this and the other rose perfumes can scarcely be called in question. The present supply of the European and American markets is derived chiefly from Turkey and from the perfumery region of the south of France. The attar or oil of roses is produced most largely in Bulgaria and parts of other Balkan states as well as in Asiatic Turkey, principally from the damask rose, which may be taken as a form of *Rosa gallica*. A white-flowered rose, *R. alba*, is much grown in the more exposed situations, as it is considered harder than the red-flowered damask rose. It is very free in bloom and productive of oil, which is, however, inferior in quality. The attar is obtained by distillation, which is there conducted in a crude manner. In the Grasse district (southern France), the rose-water, obtained as explained above, is considered to yield more profit than the attar, which is rather regarded as a by-product of the distillation.

But the best rose perfumes in France are extracted by maceration, finishing with *enfleurage*, processes that secure the true rose odor, which is not altogether represented by attar or rose-water. Rose pomade and its alcoholic extract are perhaps the finest of rose products. What is known as the Provence rose, a hybrid or variety of *Rosa centifolia*, the type to which the cabbage or hundred-leaf rose of old gardens and the moss roses belong, is almost exclusively used in France and also in Germany, where a limited quantity of very fine attar is produced.

The centifolia and gallica varieties of perfume roses, as well as a hybrid of *Rosa rugosa* under the name of Rose Parfum de L'Hay, have been tried in this country with encouraging results as far as facility of culture, quantity, and quality of perfume-content are concerned, but the economic possibilities of rose-culture here for this purpose are far from being worked out at this time. These varieties are all quite hardy and may, without doubt, successfully be grown over a vast extent of country, though for practical perfume-production the warmer climates, coupled with abundant summer moisture, seem to be needed. Deep fertile and retentive but well-drained clay or loam soils are best adapted for rose-culture, and these may be had in abundance in the Southern and Middle Atlantic states, where the future rose industry of the United States, when it becomes a commercial possibility, may be expected to develop. The luxuriant growth of roses on the Pacific Coast has long attracted attention, but exuberant vegetation does not always imply a rich perfumery-content, and there is a suspicion that the cool fogs of the coast and the hot aridity of the interior

valleys of the Pacific States do not favor perfume-production, however stimulating local conditions may be to vegetative growth; but direct experiments in this connection appear to be lacking.

The centifolia and gallica roses have practically but one season of bloom in this country. They are covered with flowers in May or June, according to the latitude in which they are grown, producing only occasional blooms in the fall, the gallicas being most free in this respect; but the hybrid with *R. rugosa* has a long blooming season, with repeated crops coming on in late summer and autumn. This peculiarity might be of advantage in localities where labor is scarce, as a smaller force of workers could care for the same amount of bloom developing over a longer season. The perfume of the hybrid rugosa is of the most exquisite quality and the yield somewhat greater than of the older types of perfume roses, but there is greater difficulty of propagation, as rugosa varieties are increased only by budding or grafting, while the centifolias and gallicas are freely propagated by means of layers or cuttings.

the main question being that of efficient labor for promptly collecting the blooms during the relatively short productive season. It requires in this country, as abroad, fully 3,000 pounds of fresh rose petals to produce a pound of oil, valued at the present time at \$125, or more if of really high quality. The value of the rose-water represented by this amount of oil would be considerably greater.

The oil distilled from the green parts of the common rose geraniums, *Pelargonium capitatum* (?) and *P. Radula*, resembles in fragrance the oil of roses and is largely used as a substitute for it. Although generally not sold at retail under its own name, it is in itself a legitimate perfume, and its production should be undertaken in this country—only, however, in the South, where the long season admits of three crops of leaves and where the stumps with the soil heaped around them will survive the winter. The largest crop is to be had on rich lowland, but the finest quality is produced on drier and less fertile ground. In France, it is now grown mainly on irrigated land, but the product has to be ameliorated by the admixture of oil from drier localities. The rose geranium is largely grown in Algeria, and in Spain, Sicily, and so on, as well as in France.

2868. Perfumery plants: *Iris florentina*, *Jasminum grandiflorum*, *Lippia citriodora*.

The production of high-quality rose-water, rather than attar, appears likely to be more profitable in this country, as the latter requires repeated distillations, or washing out by ether and subsequent evaporation of the menstruum, and realizes a relatively less price in market on account of competition with adulterated imported oils and synthetic imitations.

The type of rose bloom best suited for perfume purposes is semi-double, with large, thick petals that can easily be collected, rather than the more showy varieties with full disks of shorter petals so crowded that they hide the pistils. Many of the latter varieties possess exquisite fragrance and possibly a satisfactory oil-content, but are seldom sufficiently vigorous or free in bloom to offset the added difficulty of manipulation. In a field trial of "Princess Bonnie," one of the most fragrant of American-raised hybrid tea roses, not enough blooms could be collected at a given time for a practical distillation. New varieties will be developed especially adapted to the purpose as interest in rose-perfume production increases, and those with peculiarly attractive odors may become available for the grease process, when not altogether suited for distillation.

The culture of perfume roses and the extraction of their fragrance present no difficulties to American skill,

Geranium oil, in turn, has its substitutes, among which the oil of lemon-grass from India is conspicuous.

The European sweet violet, *Viola odorata*, affords the finest example of a favorite type of odors quite different from the citrine and the rose. The oil of the violet itself is necessarily so expensive as to be little used. The large amount of flowers required and the amount of hand labor necessary for gathering such small flowers, each growing on a separate stem, are apparently insurmountable obstacles to the extensive use of true oil of violet. Still it may be presumed that there will permanently be a class of buyers willing to pay the necessary cost of so choice a perfume. The violet yields its full fragrance only southward, but it must be grown in partial shade. When labor conditions admit, true violet perfume may be produced in California and in the South. An expert grower of violets has even thought that they might be grown under glass for this purpose.

Of the same general type and in some wise a substitute for violet perfume, is that of *Acacia Farnesiana*, the "cassie" of the French, known in the South as "opopanax." The small yellow balls of flowers are treated by the grease processes, particularly maceration. While not ranked so high as violet, the perfume is in entirely good standing and produced in large

quantities. The flowers, dried with proper care, have a market value for sachets. The opopanax tree grows freely in Florida, is apparently native in Texas, and is suited to the climate of Arizona and southern California. The labor of picking the flowers would be somewhat expensive. Several other acacias are eligible for perfumery use.

To the same group belongs the perfume of orris- or iris-root. It is afforded by the rootstocks of three species of iris, formerly gathered wild and now cultivated near Florence and at other points in Italy. The species are *Iris germanica* (Fig. 1968, Vol. III), *I. pallida*, and *I. florentina* (Fig. 2868), the first of these being our common garden iris, with deep blue flowers, the second a paler-flowered species, the third having white flowers. High authority affirms that the use of the first two species is only a falsification, and, in fact, that the root of *I. germanica* causes serious inflammations. It is certain that the first two are extensively grown; but *I. florentina* alone appears to be much used for distillation. When cultivated, the iris is generally propagated by root-division, the cuttings being placed for the first year in a nursery, afterward set in rows a foot apart. It is grown in stony dry soils on hillsides or mountains. The crop is gathered once in two or three years. The cuticle is scraped from the root, which after being dried in the sun is stored in a dry place for the development of its fragrance. This is wanting in the fresh root, and does not reach its maximum under three years. When distilled, the root yields "orris butter," but it is more largely used in the form of an alcoholic tincture or ground up for sachets. There is no reason why orris-root should not be grown in many parts of this country, but the returns at present are not large.

Another important group of perfumery plants consists of several members of the mint family. Peppermint and spearmint (Fig. 2359, Vol. IV) can hardly be placed in the perfumery class, but lavender, thyme, and rosemary could not easily be spared from the perfumer's resources. Lavender is native on dry slopes in the Mediterranean region, and the oil is most largely produced in the region of the maritime Alps. The plant has been introduced, however, into some of the southern counties of England (Mitcham and Hitchin being the centers), and found to produce there an oil which has commonly been regarded as far superior to the French, and at any rate is different in kind (see *Mentha*). The English lavender is grown in light and well-drained calcareous soils. In well-drained ground, lavender will bear some cold, especially if protected, but profit cannot be looked for far north. Lavender of the French type may be expected to succeed in California out of the reach of the trade-winds, and may perhaps not require irrigation. There are shallow calcareous soils in the "black belt" of the Gulf States which might perhaps yield an oil like the English, and the same may be true of some tracts northward on the Pacific slope. Lavender is treated by distillation, and it is said in England that direct contact with the water yields better results than the application of dry steam. (See, also, *Lavandula*.)

Thyme (chiefly the garden thyme, *Thymus vulgaris*) furnishes a perfume particularly suited to soaps and imported into this country in large quantities. Rosemary has a stimulating property and is an essential ingredient in Cologne water. Both of these could quite possibly be grown, say in California, but might not be able to compete well with the spontaneous product of Europe.

Some notice should be taken, too, of the rather humble group of odoriferous plants belonging to the parsley family, including anise, caraway, and fennel. Not only are the oils of these three (chiefly anise) largely imported but also their seeds (chiefly caraway). Caraway runs wild northerly, fennel has established itself on the lower Potomac, and anise could doubtless be grown, but

there is no reason to expect large profits from these plants.

There are several plants deserving consideration which do not fall into any of these groups. One is the jasmine (*Jasminum grandiflorum* and *J. Sambac*) (Fig. 2868). This furnishes almost the only odor which cannot be imitated by combinations of others. The oil of jasmine is very valuable. The plants can be grown in our warmest regions. The tuberose furnishes another choice perfume and has been very successfully grown for the purpose in Florida and South Carolina. (See *Polianthes*.) The heliotrope (Fig. 1801, Vol. III), jonquil (Fig. 2448, Vol. IV), and mignonette are also to be named. Of a quite different scent from any of these is the oil of bitter almond, so important for fine soaps. This so-called oil is a poisonous compound formed in the process of fermenting the cake of the kernels from which the fixed oil has been expressed. Its production should be considered in our almond-growing regions, especially California.

Several tropical grasses of the genus *Cymbopogon*, including *Cymbopogon Schænanthus*, which yields the previously mentioned lemon-grass oil, are of easy culture in Florida and the Gulf States generally, and doubtless will be largely used in the future for the production of fragrant oils having a wide range of usefulness, especially in the form of combinations for scenting soaps. Those best known are vetiver, *Vetiveria zizanioides*, citronella, *C. Nardus* and the true lemon-grass, *C. citratus*, not possessing the geranium-like odor found in *C. Schænanthus*. With the exception of vetiver, which contains the fragrant principle in the roots, the leaves and flowering parts of the *Cymbopogon* grasses are used for distillation.

Of our native growths there are some which are already utilized as the source of scenting materials. The root of sassafras is or has been distilled in Pennsylvania, Maryland, and Virginia, and in other northern states, and sparingly southward. Wintergreen, *Gaultheria procumbens*, is distilled in small quantity in several eastern states, but has very largely given place to sweet or cherry birch, *Betula lenta*, which yields a similar oil with less expense. The wood of the red cedar, *Juniperus virginiana*, has long been distilled in Germany, and latterly in this country. It furnishes a finer cedar-of-Lebanon perfume than the cedar of Lebanon itself.

Three native plants representing respectively the thyme-like and citrine odors,—widely known as weeds but amenable to cultivation over a great extent of country,—are wild bergamot, *Monarda punctata*, mountain mint, *Pycnanthemum albescent* and Canada fleabane, *Erigeron canadense*. The first two yield oils useful for soaps as well as for the production of thymol, now a valued medicament, while the latter contains a high percentage of limonene that may largely displace turpentine in the manufacture of agreeable varnishes for inside uses.

The root of the wild ginger or Canada snakeroot, *Asarum canadense*, yields a fragrant oil quoted in market reports, and said to be used especially for strengthening other perfumes. The sweet goldenrod, *Solidago odora*, furnishes an oil which has a market standing. The rich odor of the yellow jessamine of the South has been successfully extracted in Florida. The common market perfume of magnolia is doubtless mostly or entirely an imitation, and the same is probably true of *Clethra alnifolia* perfume. The great magnolia, *Magnolia grandiflora*, abounds in the South, but its flowers might be difficult to secure in quantity. *Clethra* is abundant enough in the Atlantic Coast region, but some difficulty might be experienced with it owing to the fact that only a part of the flowers in the raceme open at one time. The flowers of the swamp magnolia or sweet bay, *Magnolia virginiana* or *M. glauca* (Fig. 2298, Vol. IV), should be tried. The spice bush, *Benzoin æstivale*, affords several scents. The sweet

and copious bloom of *Rhododendron arborescens* in the southern mountains has been suggested for treatment. It is to be feared that the delicious odor of the native crab-apples would be too expensive, considering the difficulty of collecting enough petals. The bloom of the wild grape might well be thought of. Many of our plants—these are only examples—will eventually be tried and a few will be found steadily valuable. It is useless to expect commercial success with small and scanty-flowered plants like trailing arbutus, *Epigaea repens*, however pleasing in their natural state.

The production of perfumery oils may be conducted on large farms by capitalists; or a central establishment may contract with individuals for flowers, and other materials; or the business may be conducted coöperatively; or individuals may operate on a small scale in connection with other lines of farming. Some competent women to whom other avenues are closed may find this work available and congenial.

Intending experimenters should seek further information in one or more of the books which are before the public. With regard to methods of extraction, Askinson's "Perfumes and Their Preparation" may be confidently recommended. Sawer's "Odorographia" (especially the first series) is valuable both to the extractor and the grower. Piesse's "Art of Perfumery" will also be found useful on both sides of the subject. Gildemeister and Hoffman's "Volatile Oils" is also very valuable. Also consult E. S. Steele's article on "Perfumery-Gardening" in the Yearbook of the United States Department of Agriculture for 1898. Vol. XXII, part 2, of the Journal of the Royal Horticultural Society (London, 1898) contains a list of perfumes and plants that yield them, and also a list of books on perfumes.

E. S. STEELE.
W. VAN FLEET.†

PERGOLA. The word "pergola" closely interprets its original meaning: from the Latin "pergula," a projecting roof, shed, or vine arbor, from "pergere," to reach forward or project; and from the Italian "pergola," a grape which remains upon its trellis all winter. From this derivation and use of the word, it will readily be seen how the term has become one of common usage in modern garden design, rightly or wrongly to designate almost any type of arbor or vine-support in the present-day garden. In order to understand the purer and less general meaning of the word, the garden vine-supports may be divided into two kinds or types: (1) treillages, decorative or otherwise, which may broadly be considered as designed in one simple geometric plane, perpendicular to the garden, their dimensions, height, and length being determined only by their use and detail design; and (2) pergolas and arbors, designed or planned in three planes, having height, length, and breadth, and, in brief, being architecturally conceived tunnels over which vines are trained or grown, the arbor and the pergola differing only in the detail of their design.

The pergola is invariably flat-topped, its semi-open roof being formed either by rustic poles or timbers of varying size, laid at right angles to the length of the structure, or by similarly laid but regularly spaced rafters or timbers of definite size and cut, this partially open roof being supported in either case by posts or columns of an architectural character equally and oppositely spaced. In simpler description, the pergola is a horizontal vine-support raised upon piers or columns, each of the latter standing free and independent of the other, the vines being encouraged to lie flat over its top.

The arbor, in distinction from the pergola, is, in its simplest form, a treillage or vine-support of a skeletonized form, with sides and top generally alike, its top, or roof, being flat or curved as its design may determine. In detail, its construction consists usually of regularly and oppositely spaced wooden posts sup-

porting not over-thick strips and rails of the same material, these extending horizontally. Other material than wood is often used in arbor-construction, but the design and character remain generally the same,—a skeletonized tunnel for the support and training of vines over its entire surface. Therefore, while similar in origin and use in the garden, the pergola and the arbor must not be confused in their character and design. The arbor is, in fact, a development of the even earlier-used pergola, which in medieval gardening often became the pleached alley (or allée), and in the early French and English gardens the very decorative and often complicated tunnel or gallery of treillage.

The pergola is numbered among the oldest pieces of garden architecture extant. The Egyptian used it as a covered walk from one part of his domicile to another, or to his garden house; Pompeii and ancient Rome prove its constant use, Vitruvius, describing the garden attached to the villa of Diomedes, saying, "behind the fish pond ornamented by a fountain, there was a platform over which vines were trained on a wooden framework supported upon six columns of stucco." In Italy, the pergola can be traced through the various transitions of the Italian gardens from those of early imperial times through the medieval, to the architectural or formal gardens of the Renaissance and today. In the great medieval period, the pergola and the cloister were often synonymous in use, differing only in the material of their construction, the latter being largely the outgrowth and development of the former. As early as the beginning of the fifteenth century, the pergola was in common use in France, being found not only in the magnificent gardens of the kings, but as a feature of the smallest town gardens of Paris. Riat, in his most authentic garden history, "L'Art des Jardins," carefully notes and describes the use of the pergola at this time; Hill, one of the earliest of English writers on gardening, in his "Gardener's Labyrinth," published about the middle of the sixteenth century, claims the pergola to be "so winded that the branches of the vine, melon, or cucumber, running or spreading all over, might shadow and keep both the heat and the sun from the sitter there under, and offer him cool and shaded passage." William Horman, in his "Vulgaria," published in 1519, tells us that "alleys in gardens, covered with vines, do great pleasure with the shadow in parchynge heat, and clusters of grapis maketh a pleasant walkynge alley." Thus, in brief, it will be seen that the pergola and its close kin, the arbor, have been used in all time and manner of gardening, the earlier English colonists bringing both to America, where their popularity, especially of late, has been so great as often to cause their degeneration in design and misconception in use.

There is no decorative or useful feature in the garden scheme which has been more inadvisedly used than the pergola. Like our gardening, which has naturally become composite and therefore often impure in taste, so the pergola has become subjected to all manner of diversity in use, material, and design. It can be made an excellent motif and component of a good garden scheme, if properly and carefully considered. Its value is not as a mere floating incident, untied and non-related to some stronger element or to the frame of the garden. It must be given a "tying-together" or corridor value in order best to serve and express its use. The garden should be designed in a manner to call for its use as a covered passage between the house and the garden entrance; or to connect one garden, or part of a garden, with another; or to separate garden from garden, offering substitute for the wall, hedges, or lattice, which might otherwise be used; or allowed to enframe or terminate the garden, a situation in which it may often be used to fine advantage either alone or in combination with a garden house or shelter; but it should not be so designed and placed as to serve merely

as an isolated decorative garden feature. For such location and use there is the garden shelter, the tea-house, the pavilion, the seat, and various exedra, far more suitable.

As is generally the case with all decorative garden motifs, the design and material of the pergola should be in strict harmony with its more important and controlling architectural surroundings. This does not mean, nor does it necessarily follow, that the material of the pergola should be like that of the house, garden wall, or other more or less important adjacent architectural features; but it does mean that its architectural character or style, design, and scale, must be determined and dominated by that common to the entire problem, and its material be in harmony or at least reflective. The designer or builder is safest when he considers not only his pergola but all of the architectural features of the garden as details, the character of which are to be largely determined by, or closely interrelated with, the architectural treatment of the garden and its environment as a whole. Materials and minor methods of

expression may vary with personal taste, but architectural period and style cannot, for with a lack of appreciation of the proper architectural relation between the interrelated parts of a garden comes a breaking down of one of the most important principles of garden or other composition, namely unity of idea.

While, of course, there can be no rules governing the dimensions of pergolas, the relation of width to height is most important, as is the relation of height to length. The scale may be either human or relative. The width of a pergola or arbor, however, is seemingly best when slightly greater than its height, for if less it will appear stilted and in poor proportion. From diagrams A to E in Fig. 2869, it will readily be seen that (A), showing a proportion of 4 to 3 is less pleasing than (B), 4 to 4, or even (C), 4 to 5. When the width increases noticeably over the height, as in (D) 4 to 6, or (E) 4 to 7, there is a resultant weakening in proportion. As for length, this of course is determined by the individual problem, but in no case should the length be merely equal to, or less than, the width or height.

In summary, the dimension of the pergola should produce a form of sufficiently dominant and pleasing horizontal and perpendicular dimensions to produce a satisfactory feeling of stability and repose.

In regard to plant materials used in connection with pergolas, the effect sought is that the pergola shall count as a support for vines; the variety and kind of growth, however, must naturally be determined by the exigencies of the particular case. Vines of fine and delicate foliage, flower, and fruit are better suited to the delicate arbor or treillage, and the larger-leaved, more heavily fruited vines to the architecturally stronger and coarser pergola. Also, vines with coarse and woody stems, such as the wistaria, the grape, the bittersweet and the like, are better adapted to the true use of the pergola, as a rack upon which vines lie, not a treillage or support up which they climb or against which they are trained.

BRYANT FLEMING.

PERÍCOME (from the Greek for *around*, and *tuft*, from the tuft of hairs around the achene). *Compositæ*. A small group of hardy perennials grown for their golden yellow conspicuous flowers.

Strong-scented much-branched herbs with long-acuminate lvs. and numerous heads in a terminal corymbiform cyme; involueral bracts slightly connected by their edges,

2869. Pergolas.—Various architectural forms; also diagrams of proportions in A to E.

thus forming a bell-shaped cup: disk-fls. sticky, the anthers much exserted: achenes villous and ciliate.—There are only 2 known species, both of W. N. Amer. The genus is of little horticultural importance and is offered only by dealers in western native plants. The showy golden yellow fls. are not unattractive.

caudata, Gray. Lvs. opposite, long-petioled, triangular-hastate with crenate or entire margins, the apex and sometimes the basal lobes long, caudate-acuminate: heads many, the fls. conspicuously longer than the involucre. Rocky cañons in the mountains, Colo. to New Mex. and Ariz.—Useful in dry or exposed places.

N. TAYLOR.

PERILLA (said to be a native name in India; by others, a Greek and Latin proper name). *Labiatæ*. Herbs, one of which is sometimes grown for the colored foliage.

Erect, with opposite lvs. and small fls. in whorls of 2 that are aggregated into axillary and terminal simple or paniced racemes: calyx bell-shaped, 5-toothed, much enlarged and gibbous in fr.; corolla short-tubed, the tube not exceeding calyx, limb oblique and somewhat unequally 5-lobed; stamens 4, erect and separate; disk represented by a large gland; style 2-parted.—Two or 3 species, Himalaya region to China and Japan. The plant known in gardens as *P. nankinensis* is distinct by the color of its foliage. The lvs. are a dark wine-purple, with a bronzy luster. These colors are more or less toned with green, especially in young plants. It is an annual herb, growing about 1½ ft. high. It is considerably used in subtropical beds and for the back of ribbon borders. It is sometimes planted next to a dusty miller or other white-lvd. plants for the sake of contrast. The foliage has an odor suggesting cinnamon. In Japan the perilla is of economic importance for the production of oil.

Perillas need a sunny or at least half-sunny position. They thrive under the treatment given half-hardy annuals. Sow the seeds thinly and cover nearly an inch. Avoid planting too closely; leggy specimens are unattractive, and the plant has a tendency to become weedy. The flowers are inconspicuous and produced in autumn. Before the introduction of the coleus, this plant was much used as an ornamental flower-garden plant, but in our warmer summers it is displaced by the more brilliantly colored and free-growing forms of that plant.

frutescens, Brit. (*Ocimum frutescens*, Linn. *P. cymoides*, Linn. *Méntha perillodes*, Willd.). The typical form has lvs. green on both sides and is worthless for gardens. Annual: lvs. opposite, rarely speckled with brownish purple, only slightly wrinkled, base wedge-shaped or narrow; blade broadly ovate or roundish, pointed or blunt, hairy or not, dentate or variously cut at the margin. In the wild, it is a coarse often shaggy plant, 2-4 ft. high, with lvs. 3-6 in. long, petioles 1-3 in. long; racemes 3-8 in. long; corolla white or reddish, 2 lines long; fruiting calyx about ½ in. long. Himalayas, Burma, China, Japan. B.M. 2395.—Sparingly run wild. Following are new combinations.

Var. nankinensis, Bailey (*P. nankinensis*, Decne. *P. cymoides* var. *nankinensis*, Voss). Slightly hairy, rarely glabrous: lvs. dark purple-brown, with a bronzy luster; base wedge-shaped (rounded in strong-growing specimens); blade ovate, acute, coarsely and deeply saw-toothed, margin wavy. Seedlings are sometimes green. R.H. 1852:60; 1879, p. 272. Forms of this variety are: (1) **Var. laciniata**, Bailey (*P. laciniata*, Hort. *P. nankinensis* foliis atropurpureis laciniatis, Hort.), has lvs. cut nearly to the middle, foliage undulate, wrinkled or crisped. Colors said to be more intense. Intro. about 1872. P.G. 2:77. (2) **macrophylla**, Bailey (*P. nankinensis* *macrophylla* *compacta*, Hort.), is a large-lvd. form characterized by its almost "bell-shaped" form. The lvs. are wavy-fringed. Habit compact. (3) **Var. elatior**, Bailey (*P. nankinensis* *macrophylla*

elatior, Hort. Benary), is a taller form of var. *macrophylla*. (4) **Var. variegata**, Bailey (*P. nankinensis* foliis *variegatis*, Hort.), differs in having the foliage spotted with white. (5) **Var. microphylla**, Bailey (*P. nankinensis* *microphylla* *nigricans*, Hort.), is a small-lvd. form intro. about 1899.

WILHELM MILLER.

L. H. B.†

PERIPLOCA (Greek, *around*, and *to twine*; alluding to the twining habit). *Asclepiadaceæ*. Ornamental vines grown for the handsome glossy foliage and the fragrant flowers appearing in summer.

Twining or upright deciduous or evergreen shrubs, glabrous, with milky juice: lvs. opposite, entire, without stipules: fls. in axillary or terminal cymes; calyx 5-lobed; corolla 5-parted, bearing inside at the base a 5- or 10-lobed crown; stamens 5, with very short filaments and with the anthers connected at the apex and villous; style short, with broad stigma: fr. consisting of 2 follicles, containing numerous, small, winged seeds.—About 12 species from S. Eu. to Trop. Afr., China and E. India.

The periplocas in cultivation have dark green and glossy leaves and dull-colored fragrant flowers followed by long and slender pods. *P. sepium* has proved perfectly hardy as far north as Massachusetts and *P. græca* is hardy north to New York, and can be grown even in Canada when trailing on the ground and somewhat protected during the winter. They thrive in any well-drained soil and prefer sunny positions; they are well suited for covering arbors, trelliswork and trunks of trees. Propagation is by seeds or by greenwood cuttings in summer under glass; also by layers.

græca, Linn. SILK-VINE. Deciduous shrub, twining to 40 ft.: lvs. petioled, ovate to oblong-lanceolate, acuminate, dark green and glossy above, 1½-4 in. long and 1-2 in. broad: fls. in loose, long-peduncled cymes, brownish purple inside, greenish at the margin and outside, 1 in. across; corolla-lobes oblong, spreading, villous; crown with 5 slender thread-like incurved glabrous appendages: follicles narrow, about 4 in. long. July, Aug. S. Eu., W. Asia. B.M. 2289. B.R. 803. L.B.C. 14:1389. Gn. 34, p. 78.—A vigorous and high-growing climber with handsome dark green and shining foliage remaining unchanged until late in fall. Under the name of *P. angustifolia* a narrow-lvd. form is sometimes cult., which is *P. græca* var. *angustifolia*, Jäg. The true *P. angustifolia*, Labill., is synonymous with *P. laevigata*, Ait., from the Canary Is. and N. Afr., with persistent lvs. and pubescent appendages of the crown.

sepium, Bunge. Fig. 2870. Lower and slenderer than the preceding species: lvs. lanceolate, long-acuminate, dark green and glossy above, paler beneath, 2-3½ in. long and ½-¾ in. broad: fls. in few-fl. cymes, similar to those of the preceding species, but smaller, about ¾ in. across and with revolute corolla-lobes: follicles 4-5 in. long. June, July. N. China.

ALFRED REHDER.

PERISTERIA (Greek, *dove*, from the form of the column and wings). *Orchidaceæ*. A group of stately South American pseudobulbous warmhouse orchids.

Leaves large, plicate, unfolding successively: fl.-

2870. *Periploca sepium*.
(× ¼)

spikes tall, erect or hanging; fls. nearly globular or cup-shaped, of a waxy texture, with broad concave segms. The genus is distinguished from the related genera *Acineta*, *Lacana*, *Gongora*, and the like, by the curious shape of the labellum and column. The base of the labellum (hypochil) is united with the column by broad wings (pleuridia). The upper part of the labellum (epichil) is movably joined to the hypochil.—Five species, of which 2 are commonly cult.

The chief factors in growing peristerias are moisture during the growing period, the ideal location being in proximity to water, in a temperature of 65° to 70° F., and a decided rest when growth is completed. The growing medium should consist of two-thirds fibrous sod soil and one-third peat and sand, an addition of dried cow-manure being beneficial. The pots should be well supplied with drainage. When the plant is growing freely, water occasionally with organic fertilizer until the growth is completed. Then reduce the water-supply to induce flowering when the young growth appears. An excellent specimen of *P. elata* in the Missouri Botanical Garden recently produced a flower-spike 3 feet 6 inches high and produced twenty well-formed flowers. From the first appearance of the spike until the last flower opened, covered a period of three and a half months. This noteworthy specimen was

grown over a tank of water, in a house of miscellaneous warmhouse plants, and organic manure was given freely during growth. The plant was then transferred to the cactus house to rest, enough water was given to prevent shriveling of the pseudobulbs, until the young growth appeared bearing a well-formed flower-spike: it was again transferred to its former position and watered freely to develop the spike. (G. H. Pring.)

elata, Hook. DOVE-FLOWER. HOLY-GHOST-FLOWER. Fig. 2871. Pseudobulbs 4-5 in. high, bearing several strongly veined lvs. 2-3 ft. high: fl.-st. 3-4 ft. high; fls. in a raceme covering about one-third the length of the fl.-stalk, cup-shaped, creamy white, wax-like and fragrant, 2 in. across; sepals broadly ovate to rotund; petals more delicate; labellum fleshy, broadly obovate, truncate, sprinkled with deep purple; column with large, curious wings, supposed to bear resemblance to a dove. June-Sept. Panama. B.M. 3116. Gng. 5:151. V. 8:163. Gn. 12, p. 153; 30, p. 574; 42, p. 324. R.H. 1876, p. 133; 1877:110.—The labellum and wings of the column are sometimes spotted with purple. Intro. into cult. in 1826.

péndula, Hook. Pseudobulbs ovate-oblong, 4-5 in. high, bearing lanceolate, strongly veined lvs.: scape

pendulous, from the base of the pseudobulb, bearing as many as 20 fls.; fls. globular in outline, 1½ in. across, fragrant, greenish white outside, tinged with rose and thickly dotted with purple within; sepals roundish concave, united at base; petals rather smaller; labellum fleshy, curiously shaped, inclosed within the fl. Guiana. B.M. 3479. G.C. II. 25:116.—Requires tropical treatment, but rarely flowers in cult.

cérina, Lindl. Pseudobulbs oblong-ovoid, up to 3 in. long, 3-4 lvd.: lvs. oblong-lanceolate, up to 1 ft. long; scape pendulous, short, bearing a dense raceme of 6-10 fls.; fls. about 1 in. across, pale lemon-yellow, waxy; sepals and petals broadly ovate, concave; lip 3-lobed, the acute lateral lobes ovate, the midlobe emarginate, inflexed, the margin crisped. Cent. Amer. B.R. 1953.

P. aspera, Rolfe. Pseudobulbs ovoid-oblong: racemes dense, 8-10 fld.; fls. light brownish yellow, densely spotted with reddish brown, the front lobe of lip brownish crimson; sepals and petals elliptic-oblong, obtusish. Venezuela. L. 267.—*P. Humboldtii*, Lindl. = *Acineta*.

GEORGE V. NASH.†

PERÍSTROPHE (Greek, *peri*, around, and *strophos*, belt; alluding to the involucre). *Acanthaceae*. Greenhouse plants, grown for the bloom.

Erect, branched or loosely creeping herbs or half-shrubby: lvs. entire: fls. solitary or in clusters of 2-3 surrounded by an involucre, in loose cymes or cymose panicles, or distant on slender branches; bracts of the involucre narrow; calyx deeply 5-parted, shorter than the bracts, scarious or hyaline; corolla-tube long, slender, slightly enlarged above, limb deeply bilabiate, the posterior lip narrow, erect, concave, entire or emarginate, lower lip spreading, apex 3-parted; stamens 2, a little shorter than the corolla-lips; anthers 2-celled; sterile stamens none; style filiform: caps. oblong, contracted into a solid stalk.—About 15 species, ranging from Trop. Afr. and India to the Malay Isls., Philippines, and Austral.

The plants are cultivated like jacobinias or justicias, of the same family. Cuttings taken at any time when the wood is soft will root in a warm bed in three to four weeks, after which the potted plants may be removed to a house of lower temperature. They require a rich loam mixed with some leaf-mold, and plenty of air.

speciōsa, Nees (*Justicia speciōsa*, Roxbg.). Fig. 2872. The plant erect, spreading and branched, becoming 2-3 ft. high: lvs. opposite, petioled, ovate-acuminate, smooth: fls. in clusters of 2-3 on slender branches, violet-purple, 1¾ in. long. Blooms for a long period in winter. India. B. M. 2722. L.B.C. 20:1915. B. 2:74. Gn. 73, p. 42.—A pot-plant of bushy compact habit when well grown. Good for the window. Usually thrives best in partial shade.

angustifolia, Nees. Plant low, erect, very much branched:

2872. *Peristrophe speciosa*. (×½)

2871. *Peristeria elata*.—Holy Ghost plant. (Flower ×½)

branches nearly horizontal, pubescent above: lvs. lanceolate, pointed at both ends: fls. sparse, in terminal cymes, rose-colored. Flowers freely. Java. Var. *aurea variegata*, Hort., has the center of the lvs. variegated with yellow. Useful for vases and baskets.

HEINRICH HASSELBRING.

PERIWINKLE: *Vinca*.

PERNETTYA (after A. J. Pernetty, 1716-1801; he accompanied Bougainville on his voyage and wrote "A Voyage to the Falkland Islands"). *Ericaceæ*. Ornamental plants grown chiefly for their attractive variously colored and profusely produced berries, also for their neat evergreen foliage and white or pinkish flowers.

Evergreen shrubs: lvs. alternate, short-petioled, small, usually serrate: fls. axillary, usually solitary on slender nodding pedicels, rarely in racemes; calyx 5-parted; corolla urceolate, with short 5-lobed limb; stamens 10, the anthers 4-awned at the apex: fr. a 5-celled many-seeded berry.—About 25 species from Mex. to the Magellan region, mostly in the mountains, and 1 species in Tasmania and New Zeal. Allied to *Gaultheria*, but the calyx not enlarged and rarely fleshy after flowering.

The pernettyas are low much-branched shrubs with dense and small evergreen leaves and small nodding flowers, followed by very decorative berries varying in color from white to purplish black or bluish black and remaining on the branches all winter. These exceedingly pretty shrubs are great favorites in England, but are little known in this country. *P. mucronata* and *P. angustifolia*, the hardest, are probably hardy in sheltered positions as far north as New York. They are well suited for rockeries and borders of evergreen shrubberies and also make very handsome pot-plants. They grow best in a peaty and porous moderately moist soil and prefer sunny positions, but seem to grow almost as well in any other well-drained soil; in shade they will not fruit so profusely as in the full sun. Propagation is by seeds or by cuttings of half-ripened wood in summer under glass; also by means of layers and suckers.

mucronata, Gaud. (*Árbutus mucronatus*, Linn. f.). Much-branched shrub, to 2 ft., with glabrous or sparingly hairy branches: lvs. almost 2-ranked, ovate to ovate-oblong, spiny-pointed, serrate, dark green and shining above, glabrous, $\frac{1}{2}$ – $\frac{3}{4}$ in. long: fls. solitary, nodding, globose-ovoid, white or slightly tinged pink, about $\frac{1}{2}$ in. long, on pedicels 2–3 times as long as the fl.; stamens longer than the ovary: fr. white to dark purple, $\frac{1}{8}$ – $\frac{1}{2}$ in. across, red in the typical form. May, June. Magellan region to Chile. B.M. 3093; 8023. B.R. 1695. L.B.C. 19:1848. Gn. 23:389; 59, p. 41. Gt. 34, p. 214. G.M. 40:811. M.D.G. 1898:397.—Many varieties (*P. hybrida*, Zabel), partly originated by hybridizing with the following species are cult. in English and Dutch nurseries, mostly differing in the color of the fr., which is usually indicated by the name of the variety, as vars. *álba*, *atropurpurea*, *coccinea* (F.M. 1879:339), *lilacina* (F.M. 1879:339), *nigra*, *purpurea* (F.M. 1879:339), *rosea*, *sanguinea*, Hort. Also *P. Drummondii*, *P. Cummingii*, *P. speciosa*, *P. floribunda* (G.C. II. 18:649 and III. 28:465) belong here. *P. mucronata* and its varieties are among our most ornamental fruiting shrubs in wintertime, when they are loaded with bright-colored berries contrasting well with the dark glossy foliage; they are also very handsome in spring when covered with their numerous white fls.

angustifolia, Lindl. (*P. mucronata* var. *angustifolia*, Nichols.). Closely allied to the preceding: lvs. lanceolate to linear-lanceolate, usually arched backward, smaller, not spiny-pointed: fls. somewhat smaller, on slender pedicels; anthers twice as long as filaments; style as long as ovary. May, June. Chile. B.R. 26:63.

B.M. 3889.—The plant usually cult. under this name is a narrow-lyd. form of the preceding species.

P. ciliaris, Don. Spreading shrub: lvs. oblong to narrow-oblong, serrulate, $\frac{1}{2}$ –1 in. long: fls. solitary, ovate, white: fr. almost black. Mex.—*P. ciliaris*, Lindl., not Don. J.H.S. 1851, p. 268. G.C. II. 10:89, and III. 28:463, belongs probably to *P. furens*, Klotzsch. Upright shrub: lvs. ovate to ovate-lanceolate, ciliate, to $1\frac{1}{2}$ in. long: fls. in axillary, secund, rather dense racemes: fr. brownish red. Peru, Chile. B.M. 4920.—*P. Pentlandii*, DC. Similar to *P. mucronata*, but lvs. not spiny-tipped: fr. dark purplish blue, with the calyx-lobes fleshy. Venezuela to Chile. B.M. 6204.—*P. phyllireafolia*, DC. Similar to *P. mucronata*: branches sparingly hispid: corolla ovate, pubescent inside; anthers twice as long as filaments. Peru, Chile.—*P. pilosa*, Don (*Arbutus pilosa*, Graham). Prostrate shrub, with densely hispid branches: lvs. elliptic-oblong, serrate, to $\frac{3}{4}$ in. long: fls. ovate, white, solitary. Mex. B.M. 3177.—*P. ruplicola*, Phil. Closely allied to *P. mucronata*: lvs. smaller, with few minute teeth: fls. on pedicels scarcely twice as long as fl.; stamens not exceeding the ovary. Chile. Sometimes cult. as *P. mucronata*.—*P. ruplicoloides*, Schneid. Supposed hybrid of the preceding species and *P. mucronata*.

ALFRED REHDER.

PERÓVSKIA (after B. A. Perovski, about 1840, governor of the Russian province Orenburg). Also spelled *Perowskia*. *Labiataæ*. About 4 herbaceous or shrubby plants from Cent. Asia, allied to *Salvia*, with opposite serrate or pinnatifid lvs. and rather small heterostylous fls. in whorls usually arranged in terminal spikes: calyx tubular-campanulate, 2-lipped; corolla 2-lipped, the upper lip unequally 4-lobed, the lower undivided; 2 sterile and 2 fertile stamens, the latter with 2 distinct contiguous anther-cells: fr. consisting of 4 ovoid-oblong nutlets inclosed by the calyx. The only species in cult. is *P. atriplicifolia*, Benth. Shrub, to 5 ft., erect, of aromatic sage-like odor when bruised: sts. hoary-tomentose: lvs. ovate-lanceolate to lanceolate, acutish, unequally and coarsely serrate, at first pubescent, finally nearly glabrous, glandular, $1\frac{1}{2}$ – $2\frac{1}{4}$ in. long: fls. blue, about $\frac{1}{2}$ in. long, in 2–6-fld. remote whorls arranged in slender spikes forming terminal panicles 1– $1\frac{1}{2}$ ft. long; calyx densely villous. Aug., Sept. Afghanistan to W. Himalayas and W. Thibet. B.M. 8441. R.H. 1905:344. G. 33:511; 36:539.—Handsome shrub, valuable for its late blue fls. forming a pleasing contrast with the silvery gray sts. Not quite hardy N., but if killed partly back, it sends forth young shoots which will flower the same year. It prefers sunny positions and well-drained loamy soil. Prop. is usually by greenwood cuttings, which grow readily in summer under glass.

ALFRED REHDER.

PERSÈA (ancient Greek name of an Egyptian tree with sweet fruit; derivation unknown, probably from *Perseus*). *Lauraceæ*. Woody plants sometimes grown for ornament; and one of them yields the avocado, one of the best of the semi-tropical fruits.

Leaves alternate, entire: fls. small, hermaphrodite, usually in panicles; corolla wanting, the calyx deeply 6-parted; stamens usually 12, in 4 series, with one series sterile; ovary sessile and tapering into a slender style bearing a simple stigma.—Shrubs and trees distributed throughout the tropics and subtropics, most of the species being confined to S. Amer., but one coming from the Canary Isls. and a few from S. E. Asia. As defined by Bentham & Hooker, the genus contains about 100 species, but Meissner (DC. Prodr. 15, pt. 1, 43) distributes some of the species in other genera and retains only 50 in *Persea*. Mez, in his monograph on the American *Lauraceæ* (Jahrb. Königl. Bot. Gart. 1889, 5, 135), describes 47 American species. *P. gratissima*, the avocado, widely cult. throughout Trop. Amer. and elsewhere for its fr., is the only species of great economic importance. Others are of ornamental value, and may prove useful as stocks upon which to bud or graft the avocado, although experiments have not been very encouraging up to the present. *P. Borbonia* grows naturally as far north as N. C.; *P. indica* is now and then seen in cult. in Fla. and Calif. Some of the Cent. American types referred to *P. gratissima* seem distinct, and may be found to constitute good species.

A. Outer calyx-lobes distinctly shorter than the inner.

Borbônia, Spreng. (*P. carolinensis*, Nees). **RED BAY**. **BULL BAY**. Tree, reaching 40 ft., with smoothish branches: lvs. 2-3 in. long, oblong to lanceolate-oblong, glabrous and deep green above, glaucous beneath: fls. pubescent, the peduncles of the clusters shorter than the petioles: fr. a small blue drupe. Woods, N. C. to Fla.—A handsome evergreen, with wood useful for cabinet work and other purposes.

AA. Outer calyx-lobes equaling the inner, or very nearly so. **indica**, Spreng. Handsome tree, with elliptic-oblong or lanceolate-oblong attenuate-acute glabrous lvs., 3-8 in. long: panicle 3-6 in. long, the peduncles compressed, and the branches 3-5-fld., the fls. white and $\frac{1}{4}$ in. long: fr. scarcely fleshy. Canary Isls., Madeira, and the Azores.

gratissima, Gaertn. f. (*P. americana*, Mill.). **AVOCADO**. **ALLIGATOR PEAR**. **AHUACATE**. **AGUACATE**. **AVOCAT**. **AVOCATO**. **ABACATE**. Fig. 2873; Figs. 445, 446, Vol. I. A large tree, commonly with broad crown up to 60 ft.: lvs. oblong-lanceolate or elliptic-lanceolate to oval or

obovate, 4-10 in. long, 2-6 in. broad, apex acute or shortly acuminate, sometimes almost blunt, the base acute to truncate, frequently rounded, surface glabrous above, usually somewhat glaucous with the venation prominent below; petiole $\frac{3}{4}$ -2 in. long, canaliculate above: fls. shortly pedicellate, in broad compact panicles at the ends of the young branchlets, about $\frac{3}{8}$ in. across, greenish, the calyx-lobes oblong-lanceolate, acute, slightly concave, finely pubescent; fertile stamens 9, in 3 series, each stamen of the inner series bearing just above its base 2 oval flattened orange-colored glands; filaments slender, finely hairy, the anthers oblong-ovate, dehiscent by 4 valves hinged distally, the 2 outer series dehiscing extrorsely, the inner series with the 2 distal valves extrorse and the proximal pair introrse; staminodes 3, flattened, orange-colored; ovary ovate-elliptic, the style slender, attenuate, finely pubescent: fr. a large fleshy drupe, commonly pyriform, ovate or spherical, 2-8 in. long, green, maroon or purple in color, the epicarp membranous to thick and woody, mesocarp soft, yellow, and buttery; seed 1, large, conical to oblate, inverted, exalbuminous, with 2 thin seed-coats often distinct, reticulated. Certainly indigenous in Mex. and Cent. Amer., extending perhaps to N. S. Amer.

The avocado is cultivated commercially in Florida and California, as well as in other parts of tropical America. See *Avocado*. Several distinct forms are known in cultivation, some of them having been considered botanical varieties by certain botanists. The horticultural varieties grown in the United States are

generally grouped into three types, which may be distinguished as follows:

A. Lvs. anise-scented: skin of fr. thin and soft.

1. Mexican type

AA. Lvs. not anise-scented: skin of fr. thick.

B. Surface of fr. usually smooth; skin leathery, usually not more than $\frac{1}{8}$ in. thick; seed-coats frequently distinct, the outer one adhering to wall of seed-cavity; cotyledons often rough.

2. West Indian type

BB. Surface of fr. usually rough or warty; skin brittle, granular, $\frac{1}{8}$ - $\frac{1}{4}$ in. thick; seed-coats adhering closely to the nearly smooth cotyledons.

3. Guatemalan type

Occasional forms will be found which are difficult to classify by the above key. Especially is this true of the Guatemalan type, of which there are several varieties in California with the skin no thicker than in some varieties of the West Indian type, and nearly as smooth. These can usually be distinguished, however, by the character of the seed and its coats. Solano and Blakeman may be mentioned as smooth-skinned examples of this class. Trees of the Guatemalan type usually have darker-colored foliage than those of the West Indian, and ripen their fruit from January to April, while the West Indian ripens from July to November. The Guatemalan type is considerably the hardier of the two. Both are greatly exceeded in hardness by the Mexican type, which has been known to withstand temperatures of 18° to 20° without serious injury. Chappelow, Ganter, and Harman are varieties of this type well known in California, where they originated. This type is exceedingly common in northern Mexico; the Guatemalan type is found in southern Mexico (whence are derived many of the varieties cultivated in the United States), Guatemala, and doubtless in other Central American states. The West Indian type is the commonest one in Florida, Cuba, and the West Indies in general, and on the eastern coast of South America. The well-known Florida varieties, Trapp and Pollock, are representatives of it.

P. drymifolia, Cham. & Schlecht., is now considered to be a form of *P. gratissima*; it is the type with anise-scented lvs. and small, thin-skinned frs. described above as Mexican. Mez recognizes it as a botanical variety, and describes it along with another variety, *P. gratissima* var. *Schiediana*, also indigenous to Mex.—The hardy avocado or yas of San José, Costa Rica, has been referred by Wercklé to *P. frigida*, Lind., but this name is of doubtful validity. The fr. is figured by Collins (Bull. 77, Bur. Pl. Ind.), and is said to be of possible value for hybridization with more tender species. It is spherical, about 3 in. diam., with a very large seed.—*P. lingue*, Nees, and *P. Meyeniana*, Nees, are two species which have recently been intro. to the U. S. from Chile.

F. W. POPNOE.†

PÉRSICA: *Prunus*.

PERSICÁRIA: *Polygonum*.

PERSIMMON. Interesting and valuable edible fruits.

Of edible persimmons, two distinct types are grown in this country,—*Diospyros virginiana*, the native species, and *D. kaki*, the Chinese-Japanese species, known as the kaki. The latter is much the more improved, and is the source of the commercial persimmons. See *Diospyros*. Other species have been introduced, but are yet under experiment (cf. "Yearbook, United States Department of Agriculture," 1911, page 416).

The native persimmon.

The American persimmon (*Diospyros virginiana*) is found wild in most of the southern states and as far north as 38° latitude. It will thrive and ripen its fruit, however, as far north as Rhode Island and the Great Lakes. The fruit is little known except to those who live in localities in which it grows wild, and even there

but little attention has been given to its cultivation and improvement. The tree is usually of small size when grown in the open ground, reaching a height of 20 to 30 feet; when grown in the forest, it often reaches a height of 60 to 80 feet; and in the rich alluvial river bottoms, from 2 to 3 feet in diameter. In exceptional cases, it may attain still greater size, even to 7 feet in circumference and 125 to 130 feet high ("Journal Heredity," November, 1915). The wood is hard and elastic, and very durable when used for inside work but it will rot quickly when placed under ground.

The fruit is subglobose and ranges in size from $\frac{1}{2}$ to 2 inches in diameter, depending largely on the number of seeds which it contains, although seedless varieties an inch in diameter are sometimes found. The fruit has a very disagreeable astringent quality when green, but this disappears in most varieties when it becomes fully ripe. The date of ripening in the central states varies from August 1 to December 1. The old notion that this fruit must be subjected to the action of frost before it becomes edible is erroneous; many of the very best varieties ripen long before the appearance of frost, while others never become edible, being so exceedingly astringent that neither sun nor frost has any appreciable effect on them.

The persimmon is readily propagated from seeds, which should be procured in autumn or early winter and planted in the same way as peach pits; but as the seedlings, especially from cultivated varieties, cannot be relied upon to reproduce themselves, they should be budded or grafted when two or three years old. This should be done in the spring as soon as the bark will slip freely. Ordinary shield-budding works well; also annular- or ring-budding, patch-budding, and chip-budding. Large trees may be cleft-grafted, and small shoots or stocks may be whip-grafted.

This tree is more difficult to transplant successfully than almost any other kind of fruit. If too much of the long tap-root is cut off, the tree will be sure to die. Transplant in the autumn, cut back most of the top, but preserve as much of the root as possible, and plant in a deep well-prepared soil. The persimmon will do fairly well on almost any land not too wet, but it will give good results if planted on a rich warm soil, well exposed to the sunlight, and kept well tilled for the first few years after planting, until it becomes adapted to its new surroundings. The orderly growing of persimmon trees in nurseries will remove much of the difficulty in establishing the plantation. The tree and fruit are little attacked by insects and fungous diseases.

The trees should be planted in the orchard 2 or 3 inches deeper than they stood in the nursery. The trees may be kept low-headed so that the fruit can be picked by hand; in this case, they may stand 16 to 20 feet apart each way. If the fruit is not to be hand-picked but gathered as it falls and size and quality are not so important, the trees may stand at about one-half these distances. As the roots run deep, the plantation is adapted to other crops until the tree require the space.

Several chance seedlings of superior size or quality have received names. They are small fruits, yellow or reddish in color, about $1\frac{1}{2}$ to $1\frac{3}{4}$ inches in diameter. Some of the forms are shown in Figs. 2874 and 2875.

For a general horticultural account of the native persimmon, see W. F. Fletcher, *Farmers' Bulletin No. 685*, United States Department of Agriculture (1915), from which most of the following descriptions of varieties are taken.

Boone (Daniel Boone).—Origin Indiana, where it ripens during October and November; form roundish oblate, size medium, color yellow, with a dull blush in the sun; skin rather tough; seeds numerous; flavor sweet but not rich; quality good.

Burrier.—Origin central Kentucky, where it ripens rather early; form oblate, size medium, color yellow; practically seedless; flesh soft; quality very good.

Delmas.—Origin Scranton, Mississippi, where it ripens during October and early November; form roundish oblate, size medium

to large, color reddish yellow; skin thin and tough; seeds numerous; flavor sweet and rich; quality very good.

Early Bearing.—Introduced from Cartersburg, Indiana, where it ripens early in October; form round-ovate, size medium, color dull yellow; quality good.

Early Golden.—Origin Illinois, where it ripens in September; form oblong, size medium to large, color yellow; skin thin; seeds few, flavor sweet; quality very good.

Golden Gem (Fig. 2875).—Introduced from Borden, Indiana, where it ripens from August to October; form roundish oblong, size medium to large, color dark orange to red; seeds few, flavor rich and sweet; quality good.

Hicks.—Origin Washington County, Indiana, where it ripens in October; form roundish oblate, size medium to large, color dark red; skin thin and tender; seeds few, flavor rich; quality very good.

Josephine (American Honey, Honey) (Fig. 2875).—Origin near Bluffton, Missouri, where it ripens in September; form roundish oblate, size medium, color bright yellow, changing to pale translucent; skin tough; seeds few, flavor sweet and rich; quality good.

Kansas.—Introduced from Missouri, where it ripens in September; form roundish oblate, size rather large, color yellow splashed with red; flavor rich; quality very good.

2874. The native persimmon, *Diospyros virginiana*. ($\times \frac{1}{4}$)

Marion (Fig. 2875).—Original tree found near Fulton, Missouri, where the fruit ripens in October; form roundish oblate, size large, color dull red; skin rather tough; seeds few; quality good though less rich than some other kinds.

Miller (Fig. 2875).—Origin Jackson County, Missouri, where it ripens in September; form roundish oblate, size large, color reddish yellow, translucent; skin tough; seeds rather numerous; flavor sweet; quality good.

Ruby (Little's Ruby) (Fig. 2875).—Introduced from Cartersburg, Indiana, where it ripens during September and for some time later; roundish oblate, small to medium, yellowish red, shading to deep red; skin tender; seeds few, flavor sweet; quality very good.

Shoto.—Introduced from Danville, Indiana, where it ripens during October; form oblong-ovate, size large, color dull yellow, blushed in the sun; skin rather tough; seeds few; quality very good.

Smeech.—Introduced from Pennsylvania, where it ripens during October and November; form roundish oblate, size medium, color dull yellow, splashed with red; flavor rich and sweet; very good.

The kaki.

The Japanese persimmon (*Diospyros Kaki*) is considered by the Japanese as their best native pomological product. Although cultivated in the south of France for more than ninety years, there is no record of its successful introduction into the United States previous to about 1870. Trees were first sent to California and subsequently to Augusta, Georgia, but owing to defective roots and long delay in transit, the first and second shipments proved a failure, and not until 1876 came the first success with a few trees. All early impor-

tations of trees grown in Japan consisted of trees of small sizes with long tap-roots and no laterals; and probably the stocks on which they were grafted were not adaptable to this country. American enterprise, however, remedied this, as nurseries were established near Yokohama and well-grown trees of the best varieties were exported to the United States. Experiments were made in the South by grafting upon native stocks. This proved successful when the graft was inserted upon the collar of the root, 3 to 4 inches below the surface of the soil. The United States Department of Agriculture received a large quantity of trees from Japan about 1878 or 1879, and fearing that the winter of Washington might prove too cold the trees were sent to Norfolk, Virginia, where many bore fruit the following year. The first fruiting of which there is any record was at Augusta, Georgia, in 1879, upon trees grafted upon native seedlings growing in the forest.

The kaki, or Japanese persimmon, is a fruit for the cotton-belt. However, as regards the hardness of the

those imported from Japan. Inasmuch as the native stock is used, the range of adaptation as to soils and similar conditions is very great. As a stock, *Diospyros Lotus* is adapted to the drier parts of the West, where *D. virginiana* does not succeed. *D. chinensis* will probably be a good stock, but has not yet been tested in this country.

One of the great drawbacks in the cultivation of the Japanese persimmon has been the dropping of the flowers, so that trees and plantations may remain barren. Recently this has been shown to be due to lack of pollination (see Hume, "Proceedings of the Society for Horticultural Science," 1913). A constantly staminate variety is now on the market, the Gailey, which, if planted one tree to seven or eight trees of sterile varieties, will insure a crop so far as pollination is concerned. The Tane-Nashi, however, is self-fertile. It is to be expected that the subject of sterile and fertile varieties, and of inter-pollination, will now receive much attention, with considerable change in the practice of persimmon-growing.

Another difficulty is the great variation in fruits in the same variety or even on the same tree, in shape, size, and other characters. While the cause of all this variation has not been determined, it is known that much of it is eliminated by the good inter-pollination of which we have spoken. Hume writes: "All varieties of Japanese persimmons so far studied are light-fleshed when seedless but certain varieties always show a dark area in the flesh when seeds are present and others are always light-fleshed even when seeds are present. Both dark- and light-fleshed fruits may occur on the same tree. The physiological causes which underlie the changes in color of the flesh are not understood, and offer an interesting field for investigation."

In color, size, and surface texture, the Japanese persimmons somewhat resemble ripe tomatoes. They are now frequently seen in the northern markets. Some of the varieties ship well. Many persons do not like them at first, largely because of the very soft flesh and their sweetness, but the quality is good, it varies much in the different varieties, and the fruit is certain to find increased demand. It is eaten out of hand.

Some of the varieties ripen in August, some in November, and others intermediate between these dates. It requires some experience to determine just when the fruit has reached the proper stage to be marketed, and this varies with the different varieties. Some of the varieties have dark flesh, others light flesh, still others a mixture of the two. The light and dark flesh differ radically in texture and consistency, as well as appearance, and when found in the same fruit are never blended, but always distinct. The dark flesh is never astringent; the light flesh is astringent until it softens. The dark-fleshed fruit is crisp and meaty, like an apple, and is edible before it matures. Some of the entirely dark-fleshed kinds improve as they soften. The light-fleshed kinds and those with mixed light and dark flesh are very delicious when they reach the custard-like consistency of full ripeness. In some, the astringency disappears as the fruit begins to soften; in others, it persists until the fruit is fully ripe. The round-shaped varieties usually ripen first, the oblong are likely to last and keep the longest; these latter should be slowly house-ripened to remove the slight astringency inherent to these varieties.

The market value of the fruit is at present more or less uncertain. A large proportion of the fruit-eating people of the North do not yet know what a fine fruit the Japanese persimmon is. The fruits have to be shipped while hard and allowed to ripen after reaching destination. Commission men are likely to sell them and the public to eat them—or attempt to do so—a week or two ahead of the proper stage of ripeness; hence the Japan persimmon in its best condition is yet comparatively little known. In Japan, the dried fruit, somewhat like a dried or cured fig, is much esteemed.

2875. Native persimmons: a, Josephine; b, Marion; c, Golden Gem; d, Miller; e, Ruby. ($\times \frac{1}{2}$)

Japanese persimmons, experience demonstrates that some varieties are more resistant to excessive cold than others; but few can withstand a temperature of zero; and as a rule they are more successful below the 32° degree of latitude than farther north. Many seedlings have been produced that seem to have increased frost-resisting powers. Instances are reported in which some of these trees have withstood the winters of east Tennessee. By successive sowing of seeds from these hardier seedlings we may look for a race of trees that will be adapted to the middle sections of the United States. There is a probability, also, that importations from the north of Japan and China may considerably extend the range northward in this country. Some varieties have succeeded in central Virginia and Kentucky. Attempts to cross with the native species have so far been unsuccessful.

The best method of propagating Japan persimmons is by collar-grafting upon seedlings of the native species (*Diospyros virginiana*), which are grown either by planting the seed in nursery rows or transplanting the young seedlings from seed-beds early in the spring. The seedlings can be budded in summer, and in favorable seasons a fair proportion of the buds will succeed. Thus propagated, the trees seem to be longer-lived than

2976. Kaki, or Japanese persimmon, in various forms as grown in Florida. 1, Tamopan; 2, Hyakume; 3, Fuyugaki; 4, Triumph; 5, Beufarik (said to be *Diospyros chinensis*); 6, Gailey; 7, Tsuru; 8, Tane-Nashi. (X about $\frac{2}{3}$)

There is a great difference also in the habit of growth and foliage of the varieties. All have broad and shiny simple leaves. Some varieties make a growth of 5 to 7 feet the first year from graft, and at ten years form a tree 10 feet in height. Others assume a dwarf compact habit and seldom grow above 5 to 6 feet in height; this class is more precocious in reaching the bearing age than the taller-growing sorts, and is also likely to overbear. It is not uncommon for a three-year-old tree to yield several hundred perfect fruits. Thinning the fruit as soon as set in early summer will prevent an early failure of the tree.

Trees thrive in any soil in which the native species grows, but usually fail in wet soils. They respond well to good care and treatment, and yet they thrive with less attention than is required by most other fruits. The insects and diseases are few. In the orchard, they are set about 15 to 20 feet apart, except for very dwarf kinds. The general culture is the same as for other fruits.

Some of the varieties of kaki, now known in this country, are as follows:

Bennett.—Of medium size, measuring $2\frac{1}{2}$ by $2\frac{1}{4}$ inches in cross-section; fruit almost quadrangular-conical, the sides often deeply creased, basin shallow, fairly regular; calyx depressed; apex rounded to a rather blunt point, marked by a brown tip; color deep orange-red. Seedless, owing to lack of pollination. A remarkable fruit, noteworthy for its hardness; the original tree is a seedling some twenty years old standing in the yard of Dr. C. D. Bennett, Newark, New Jersey.

Boufari (Fig. 2876).—Size medium, $1\frac{1}{2}$ by $2\frac{1}{2}$ inches; shape round-ovate to ovate, apex rounded, slightly depressed, the remains of the pistil set in the depression, base rounded, with obtuse shallow rounded cavity; color yellowish green, the skin greasy, slightly sticky, covered with rather rusty colored hairs which are most abundant about the apex; calyx broken up and reflexed; stem short, rather stout; cells eight, pith open, seedless; flesh light-colored, very astringent before ripening and with strong odor of jimson weed.

Costata.—Medium size, conical, pointed, somewhat four-sided; diameter $2\frac{1}{4}$ inches longitudinally and $2\frac{1}{2}$ inches transversely; skin salmon-yellow; flesh light yellow, dark flesh and seeds occurring seldom, astringent until ripe, then very fine; a good keeper. Tree distinct; a rapid, upright grower; foliage lustrous; the most ornamental of all the varieties mentioned.

Fuyugaki (Fig. 2876).—Size medium large, measuring 2 by $2\frac{1}{4}$ inches to $1\frac{1}{2}$ by $2\frac{1}{2}$ inches; color deep orange-red; oblate in form, very smooth, sometimes quartered with four slight creases from the top, apex rounded, very slightly depressed with remains of style persisting, basin very smooth, regular, shallow, calyx reflexed in the ripe fruits; skin thin, tough, smooth; flesh firm, meaty when ripe, light-colored, of a deep carrot-orange; close examination shows the presence of minute widely scattered dark specks; taste sweet, of fine flavor and quality; seeds present, slightly curved along the inner face, the back rounded, brown-shiny, $\frac{3}{4}$ inch long by $\frac{1}{2}$ inch broad by $\frac{1}{8}$ inch thick. An excellent fruit and a decided acquisition.

Gailey (Fig. 2876).—Recommended as a pollinizer, not for its fruit, although the latter is good though small; fruit oblong-conical with a rounded apex and a small sharp point, dull red with pebbled surface; flesh meaty, firm, and juicy.

Hachiya.—Very large, oblong, conical, with short point; very showy; diameter $3\frac{1}{4}$ inches longitudinally and $3\frac{1}{2}$ inches transversely; skin dark, bright red, with occasional dark spots or blotches and rings at the apex; flesh deep yellow, sometimes having occasional dark streaks, with seed, astringent until ripe, then very fine. The largest and handsomest of all. Tree vigorous and shapely; bears fairly well, but is not so prolific as some of the other varieties.

Hyakume (Fig. 2876).—Large to very large, varying from roundish oblong to roundish oblate, but always somewhat flattened at both ends; generally slightly depressed at the point opposite the stem; diameter $2\frac{3}{4}$ inches longitudinally and $3\frac{1}{2}$ inches transversely; skin light buffish yellow, nearly always marked with rings and veins at the apex; flesh dark brown, sweet, crisp, and meaty, not astringent; good while still hard; a good keeper; one of the best market sorts. Of good growth and a free bearer.

Miyotan.—Round or slightly oblong, $2\frac{1}{2}$ inches diameter; average weight, five and one-half ounces; slightly ribbed; deep orange-red; flesh usually deep brown-red, but bright red- or half red- and half brown-fleshed specimens are often produced upon the same tree the results of cross-fertilization by other varieties. Tree of medium or dwarf growth; exceedingly prolific. Fruit keeps very late. The brown-fleshed specimens are edible while solid, and as early as October 1.

Okame.—Large, roundish oblate, with well-defined quarter marks, point not depressed; diameter $2\frac{3}{4}$ inches longitudinally and $3\frac{1}{2}$ inches transversely; skin orange-yellow, changing to brilliant carmine, with delicate bloom and waxy, translucent appearance; the most beautiful of all; light, clear flesh when ripe, with light brown center around the seeds, of which it has several; loses its astringency as soon as it begins to ripen; quality fine. Tree vigorous and good bearer.

Ormond (Bostrom Vining).—Small to medium, oblong, with a tapering pointed four-furrowed apex and rounded base, the large

calyx strongly reflexed; surface deep bright red, carrying a thin bloom, the skin thin and tough; flesh orange-red, becoming very soft when ripe. December in northern Florida, long-keeping.

Taber No. 23.—Medium, oblate, flat or depressed point; diameter $1\frac{1}{2}$ inches longitudinally and $2\frac{1}{2}$ inches transversely; skin rather dark red, with peculiar stipple marks; flesh dark brown, sweet and not astringent; seedy; good. Prolific.

Taber No. 129.—Medium, roundish, flattened at base; has a small but well-defined point at the apex; diameter about $2\frac{1}{2}$ inches both ways; skin dark yellow-red, with peculiar roughened surface, somewhat resembling alligator leather in appearance and markings, except that the marks are usually very small and uniform; flesh light brown, crisp, sweet, meaty, free from astringency; excellent; a good keeper and shipper.

Tamopan (Fig. 2876).—Imported recently from China, and known as the Chinese Grindstone persimmon; fruit perfectly seedless, not astringent and may be eaten when green and hard; large (3 to 5 inches diameter), sometimes weighing more than one pound, broadly oblate and constricted all the way around below the middle so that it has a turban-like shape; color bright orange-red, the skin tough and rather thick; flesh light-colored, astringent until ripe, excellent in quality; tree strong and upright.

Tane-Nashi (Fig. 2876).—Large to very large, roundish conical, pointed, very smooth and symmetrical; diameter $3\frac{1}{4}$ inches longitudinally and $3\frac{1}{2}$ inches transversely; skin light yellow, changing to bright red at full maturity; flesh yellow and seedless; quality very fine; perhaps the most highly esteemed of light-fleshed kinds.

Triumph (Fig. 2876).—Medium; tomato-shaped; skin yellow; flesh yellow; generally has a few seeds; very productive; quality of the best. Ripens from September till November.

Tsuru (Fig. 2876).—Large, slender, pointed, longest in proportion to its size of all; diameter $3\frac{1}{2}$ inches longitudinally and $2\frac{3}{4}$ inches transversely; skin bright red; flesh orange-yellow, some dark flesh around the few seeds; astringent until fully ripe, then good.

Yeddo-Ichi.—Large, oblate; diameter $2\frac{1}{2}$ inches longitudinally and 3 inches transversely; very smooth and regular in outline, with dented appearing surface and slight depression at end opposite the stem; skin darker red than most varieties, with heavy bloom; flesh very dark brown, verging toward purplish; sweet, rich, crisp; in quality one of the best. The fruit is good to eat when still hard.

Yemon (Among).—Large, flat, tomato-shaped, somewhat four-sided; diameter $2\frac{1}{2}$ inches longitudinally and $3\frac{1}{4}$ inches transversely; skin light yellow, changing to dull red, mottled with orange-yellow; distinct in color; flesh deep, dull red, brown around the seeds, of which there are usually a few; some specimens are entirely light-fleshed and seedless; there is no astringency after the fruit begins to soften; quality fine; one of the best. In form some of the fruits have the corrugations converging to the depressed apex, as it is usually figured, but most do not.

Zengi.—The smallest of all; round or roundish oblate; diameter $1\frac{1}{4}$ inches longitudinally and $2\frac{1}{4}$ inches transversely; skin yellowish red; flesh very dark, quality good; seedy; edible when still hard; one of the earliest to ripen. Vigorous, prolific.

L. H. B.†

PÉRTYA (after A. M. Perty, professor of natural history at Berne, Switzerland). *Compositæ*. A genus of about 4 shrubs from Japan, Cent. China and Afghanistan, allied to *Mutisia* but the corolla tubular and 5-parted: lvs. alternate, often crowded under the fl. heads, entire or serrulate, deciduous: heads homogamous, solitary, with 5-15 fls.; involucre campanulate, with few large, imbricate bracts; corolla tubular, deeply 5-lobed: achene pubescent, with a conspicuous dense whitish or purplish pappus. They are not particularly ornamental, but interesting for botanical collections, as hardy shrubby *Compositæ* are few. Prop. by seeds and probably by cuttings of half-ripened wood. The only species in cult. is *P. sinensis*, Oliver. Slender upright shrub, to 6 ft.: lvs. ovate to oblong-lanceolate, acutish, entire, glabrous, 2-3 in. long: heads pinkish, 10-12-fl., on slender pedicels $\frac{1}{2}$ -1 in. long; involucre nearly glabrous: achenes sericeous; pappus whitish. June. Cent. China. H.I. 23:2214.—The Japanese *P. scandens*, Schultz. Bip., which is likely to be intro., is a slender decumbent shrub with serrulate lvs., sessile somewhat larger heads with light purple pappus.

ALFRED REHDER.

PESCATO-BÓLLEA (compounded from *Pescatoria* and *Bollea*). *Orchidaceæ*. A genus established to contain hybrids between the genera *Pescatoria* and *Bollea*. *P.-B. bélla*=*P. Klabochorum* × *B. cœlestis*.

PESCATORIA (after M. Pescatore, who had a large collection of orchids at St. Cloud, near Paris). Sometimes spelled *Pescatorea*. *Orchidaceæ*. A group of orchids often united with *Zygopetalum*, but in horticultural works usually treated as a distinct genus.

Leaves equitant, tufted, without pseudobulbs: fls. solitary on sts. 3-6 in. long, from the axils of the lvs., mostly large and showy and fragrant; sepals and petals broad, concave, spreading, the lateral sepals forming a mentum; labellum clawed, lateral lobes small, middle lobe rounded, spreading; crest thick, consisting of a number of keels arranged in a semi-circle near the base of the lip; column slender, not boat-shaped.—About 12 species. For cult., see *Zygopetalum*.

Klabochörum, Reichb. f. Lvs. strap-shaped, 1 ft. or more long: fls. 3-3½ in. across, variable in color; sepals oblong, obtuse; petals shorter, all white with chocolate-purple points; labellum 3-lobed, yellowish or white, and having many purple-tipped hairs; callus sulfur-colored, with brown keels. June, July. Ecuador. Gn. 22:24.

Dayana, Reichb. f. Lvs. tufted, 6-10 in. long: fls. on short scapes; sepals oblong-obovate, acute, white, with green tips; petals rhomboid-rotund; labellum clawed, angled on each side of the base; limb oblong, emarginate, revolute on the sides, white with a callous ring which is purple-violet, the base being of the same color; column yellow, with a red band near the base and the anther of the same color. Late autumn. Colombia. Var. **rhodâra**, Reichb. f. Sepals and petals with rose tips; labellum orbicular, suffused crimson. B.M. 6214.

cerina, Reichb. f. Fig. 2877. Lvs. in tufts of 4 or 5, cuneate-oblong, pointed, 1 ft. long; peduncles 2-6 in. long, 1-fl.; sepals and petals nearly equal, the latter somewhat clawed, fleshy, rounded, concave, pale straw-color; labellum ovate, yellow, with a thick semi-circular crest. Chiriqui. B. M. 5598 (as *Huntleya cerina*). F.S. 17: 1815 (as *Zygopetalum cerinum*).—Flowers at various seasons, the fls. lasting a long time.

P. cochleâris, Rolfe. Lvs. ob-lanceolate-oblong, acute, 5-9 in. long; sepals and petals nearly equal, lower halves ivory-white, upper reddish maroon; lip 3-lobed, white; column maroon. Andes.

HEINRICH HASSELBRING.

PETALOSTEMUM (Greek for *petal* and *stamen*, alluding to the way in which these organs are joined). Sometimes spelled *Petalostemon*. By some authors, the species have been referred to *Kuhnistera*. *Leguminosæ*. American herbs, mostly western, with long or deep perennial roots, sometimes planted for ornament.

Leaves glandular, alternate; blades unequally pinnately compound; lfts. often broadest above the middle and involute: fls. perfect, in short or elongated spikes; calyx-teeth nearly equal, rather broad, shorter than the tube; corolla white, pink, purple, or violet; petals on long slender claws; standard oblong or obcordate; wings and keel-petal similar, their claws adnate to the sheath of the stamen-tube almost to its summit; stamens 5, monadelphous, alternate with the petals; ovary sessile, 2-ovuled; style subulate; pod included in the calyx, mostly dehiscent, 1-2-seeded. Distinguished from its close relative *Dalea* by having only 5 stamens instead of 9-10 as in that genus.—About 27 species. These low bushy plants with fine-cut lvs. and bearing a constant succession of showy spikes of fls. are very attractive, and well adapted for borders and rock-gardens.

A. Fls. white.

cándidum, Michx. (*Dôlea cándida*, Willd.). **WHITE PRAIRIE CLOVER**. Plants glabrous: sts. erect or rarely prostrate, simple or sparingly branched, 1-2 ft. tall:

lfts. 5-9, the blades linear, oblong or oblanceolate, ¾-1½ in. long, acute, or mucronulate, glandular beneath, more or less cuneate at base, very short-stalked; peduncles terminal, elongated, bracted; spikes cylindric, 1-4 in. long, about ½ in. thick; bracts aculeate, longer than the calyx; corolla white, 2-3 lines long; wings and keel oval; standard cordate; calyx-teeth and pod slightly pubescent. Tenn. to Minn., La., and Texas. B.B. 2 (ed. 2):369.

AA. Fls. rosy purple or violet.

B. Pubescence of the calyx of short close-set appressed hairs.

decumbens, Nutt. Plants sparingly pubescent above or glabrate: sts. solitary or cespitose, ascending or

2877. *Pescatoria cerina*.

decumbent, 1-2 ft. tall, mostly simple: lfts. 5-7, linear or linear-oblong, ¾-¾ in. long, acute or mucronulate, glandular, often involute: spikes ovoid or oblong, ¾-¾ in. long; bracts ovate-lanceolate, with subulate tips; calyx strigillose, shorter than the bracts, tube campanulate, lobes lanceolate or ovate-lanceolate, shorter than tube, acute; corolla pink or rose-purple; standard with an oblong-ovate cordate blade, other petals with oblong blades. N. E. Texas.

BB. Pubescence of the calyx villous or silky-villous.

C. Bracts glabrous or merely puberulent tips.

purpureum, Rydb. (*Dôlea purpurea*, Vent. *P. violâceum*, Michx.). **VIOLET PRAIRIE CLOVER**. Glabrous or slightly pubescent, erect, 1½-3 ft. high, branching above: lvs. short-petioled; lfts. 3-5, narrowly linear, ¼-¾ in. long, ½-1 line wide, acute or mucronate at the apex, narrowed at the base, short-stalked: spikes peduncled, oblong to cylindric, ½-2 in. long, about ½ in. thick; bracts above mucronate, nearly glabrous, nearly equaling the pubescent calyx; corolla violet to purple, about 2 lines long; standard cordate, wings and keel oblong. Ind. to Sask. and Texas. B.M. 1707. B.B. 2 (ed. 2):370.

CC. Bracts with silky-pubescent tips.

tenuifolium, Gray. **SILKY PRAIRIE CLOVER**. Erect, somewhat pubescent, branching, 1-2 ft. high: lvs. short-petioled; lfts. 3-5, linear, obtuse, glandular-dotted, margin somewhat involute, ¼-½ in. long, nearly sessile: spikes cylindric, ½-1½ in. long, about ½ in. thick; rachis pubescent; fls. rose-purple, about ¼ in. long; bracts ovate-pointed, pubescent, equaling the calyx; standard somewhat orbicular to cordate. Kans. to New Mex. B.B. 2 (ed. 2):370.

P. L. RICKER.

PETASITES (Greek, *a broad-brimmed hat*; referring to the large broad leaves). *Compositæ*. Hardy perennial herbs much like the common coltsfoot (*Tussilago Farfara*), having large leaves of the same general shape, but the flowers range from purple to white, not yellow, and are borne in corymbs instead of singly. They are rather coarse and weedy, but the big felty lvs., appearing after the very early leafless scapes, make a good cover for rough or unoccupied places.

The genus is widely distributed in north temperate and subarctic regions. The number of species is about 20; the essential character of the genus (as distinguished from *Tussilago*) is that the heads are nearly or quite dioecious, and rayless or with very short and mostly not showy rays; also the fact that the scapes usually have many heads instead of one. The lvs. are orbicular or reniform, always with a deep heart-shaped base and the scapes are covered with scales like a coltsfoot, but sometimes the lower ones are more leafy.

japonicus, F. Schmidt. Lvs. large, $3\frac{1}{2}$ –4 ft. across, radical; peduncle with 2 or 3 linear bracts: fl.-heads in a fastigiate thyrs. Isl. of Sachalin. B.M. 8032. Var. **giganteus**, Hort. Lvs. orbicular, margin wavy: fl.-heads densely clustered. Gn.M. 10:180.—The stalks are eaten as a vegetable after being boiled, and are also preserved in salt or sugar. The fl.-buds, which appear in Feb., are used as a condiment, as they have a slightly bitter but agreeable flavor. The plant has been advertised in Amer. since 1900 by several dealers. Grows as high as a man, and is useful for bold effects in the sub-tropical garden.

fragens, Presl. WINTER HELIOTROPE. SWEET COLTS-FOOT. Height 8 in.: lvs. appearing during or after anthesis, orbicular, margined with small cartilaginous teeth, glabrous above, pubescent and green below: heads fragrant, the marginal fls. of the female heads in the form of short rays; fls. small, varying from pale lilac to purple. Medit. region. Gn. 23, p. 113; 53, p. 328; 62, p. 58.—Has the merit of blooming in winter and its fls. have a delightful vanilla-like odor. A few sprays are desirable for cutting during winter. The plant also differs from the common coltsfoot in having darker colored and evergreen foliage. It is suitable for carpeting shrubberies and for dry banks of stiff clay where choicer subjects will not thrive. Like most others of the genus, it spreads rapidly by underground runners.

palmatus, Gray (*Nardósmia palmata*, Hook.). Height 6–24 in.: lvs. orbicular or somewhat kidney-shaped, deeply 7–11-cleft beyond the middle, and the lobes sharply dentate, green and glabrous above, densely white-tomentose beneath: heads fragrant, 4–6 lines across, the marginal fls. of the female heads in the form of short rays, whitish. E. Asia, N. Amer. B.B. 3:469.—Blossoms from April to June, its fls. varying from nearly white to pale blue or purplish. It is found in rich dark swamps or sphagnum bogs from Newfoundland to Alaska and south to N. Y., Wis., and Calif. It has been offered by dealers in native plants.

officinalis, Moench (*P. vulgaris*, Desf.). Height 16 in.: lvs. 3 in. to 3 ft. diam., reniform or orbicularly cordate, white-hairy below: fls. purplish, appearing before the lvs. in March–May, borne in cylindric panicles. Eu., N. Asia.

WILHELM MILLER.
L. H. B.†

PETIVERIA (named after James Petiver, 1665–1718, an apothecary and botanist of London). *Phytolaccaceæ*. Shrubby herbs: lvs. alternate: fls. small, in axillary and terminal racemes, solitary or in 2's; perianth herbaceous, conical at base, 4-parted, segms. subequal, lanceolate, spreading; stamens inserted at the base of the perianth on a hypogynous disk, either 4 alternate with the segms. of the perianth or 5–8 placed without order; ovary 2-celled.—About 2 species, S.

Fla. to Paraguay. The genus has been recently monographed by Hans Walter in Engler's *Pflanzenreich*, hft. 39 (IV. 83). *P. alliacea*, Linn. (*P. octandra*, Linn. *P. alliacea* var. *octandra*, Moq.). GUINEA-HEN WEED. Half-shrubby, perennial: sts. 2–3 ft. high: lvs. alternate, ovate, entire, membranaceous, attenuate at both ends, pellucid-dotted: infl. erect in a lax raceme; fls. rose or white. Mex. to Brazil. An ornamental stove plant probably not now in cult.

PETRÆA (Robert James, Lord Petré, 1710–1742, a patron of botany who had the finest collection of exotic plants in Europe). Sometimes spelled *Petræa*. *Verbenacæ*. Tropical American woody plants, one of which is a choice blue- or purple-flowered climber.

Twining or arborescent shrubs: lvs. opposite, leathery, pinnate-veined: fls. violet, purple or bluish, in

long terminal racemes; calyx with 5 scales in the throat; calyx-lobes colored during anthesis but often becoming green and rigid in fr.; corolla usually a little more intensely colored; limb 5-cut, oblique, the tube short and cylindrical; stamens 4, didynamous; ovary imperfectly 2-loculed; locules 1-ovuled: fr. included in calyx, indehiscent, 2-celled and 2-seeded or 1-seeded by abortion.—Species about a dozen, Mex., W. Indies to Brazil.

Petrea is well adapted to be grown with other stove climbers. The plants do well when trained to a balloon-shaped or flat wire frame, to pillars, or carried near the roof, where they add greatly to the beauty of the house. When it is intended to plant them out in the border, the first point to be considered is the drainage in the pot. This is best effected by placing a layer of brick rubbish of about 4 to 5 inches. This will keep the compost from becoming sour or stagnant in the pot. For a compost, use turfy loam four parts, turfy peat one part, well-decayed cow-manure one part, with admixture of a liberal quantity of sharp gritty sand. By the end of January the temperature may be increased to about 62° for night with 10° to 15° higher by day. Just as soon as they show renewed vigor they will not stand to become dry at the roots. They will want a good syringing over and under the foliage every morning on bright days. Give enough ventilation to keep the air pure and sweet. In midsummer they need some shade if only during the most powerful sunshine. When they are well established, they will be benefited by liquid manure once a week. For midsummer the temperature may be allowed to run up 80° or 85° with sun, and a night temperature of 70°. They are easily propagated from shoot-cuttings placed in a brisk bottom heat and

subjected to the usual condition of moisture and shade required for other plants. When they are wanted to grow in pots, keep shifting until they are in 8- or 10-inch pots. The compost may be renewed in the spring. (J. J. M. Farrell.)

volubilis, Jacq. **PURPLE WREATH**. Fig. 2878. Twining: lvs. 3-4 in. long, short-stalked, ovate, elliptic or oblong, acuminate or obtuse, entire or wavy: fls. blue, in terminal elongated racemes (7-8 in. long); calyx with a tube one-fourth to one-half as long as the pedicel, and in fr. one-third to one-fourth as long as the narrow lobes; corolla included in the calyx. Cuba to Brazil; a showy plant. B.M. 628. G.C. III. 39:24, 25; 45:252; 51:287. J.H. III. 54:390. G. 29:192. H.F. 8:50. F.E. 23:582. F.C. 3:108. Gn. 12:40.—The purple wreath is one of the most distinct and beautiful of tender climbers. The fls. are like a 5-pointed star of lilac with a violet in the middle. The fls. begin to open at the base of the raceme and the showy 5-pointed star is the calyx, whose sepals are colored like petals. The calyx spreads open while the corolla is still a round bud in the middle, and it remains after the corolla has fallen, so that the vine, at first glance, seems to bear two kinds of fls. The blooms appear in March and April. It does not bloom freely in small plants; it probably has other drawbacks, for it has always been a rare plant in Eu., though enthusiastically commended. Offered in S. Calif. The fls. seem to vary considerably in color.

WILHELM MILLER.
L. H. B.†

PETROCÁLLIS (Greek, *rock beauty*). *Cruciferae*. This genus has been commonly included in *Draba* but differs from it in technical botanical characters as follows: silique oval with swollen reticulate valves having 1-2 seeds in a cell with the funiculum adnate to the septum. One species in the Pyrenees, *P. pyrenæica*, R. Br. Height 2-3 in.: lvs. wedge-shaped, 3-lobed at apex: fls. white at first, changing to rosy pink. May. Mountains, S. Eu. B.M. 713.—Also found under *Draba pyrenæica*, page 1068; grown as a little rock-plant in choice collections.

PETROCÓPTIS (Greek, equivalent to the Latin *Saxifraga*,—to break or cleft the rock: rooting in the clefts of rocks). *Caryophyllaceæ*. Two or 3 perennials from the Pyrenees, sometimes used in alpine- and rock-gardening. Allied to *Lychnis* and sometimes united with it, differing in imbricated rather than convolute aestivation and in bearded or woolly seeds. Perennials of small size with uncut petals and a corolla-crown, the lvs. mostly tufted or in a rosette: st.-lvs. opposite. *P. pyrenæica*, A. Br. (*Lychnis pyrenæica*, Berger). Three to 4 in. high from a fusiform root: lvs. glaucous-green, spatulate, those on the st. cordate and sessile: fls. pale flesh-color or rose-color, about $\frac{1}{2}$ in. across, in forked clusters, the slender pedicels 1-fl.; petals shallowly notched at top, bearing 2 erect serrate scales. B.M. 3269. Var. *alba*, Hort., is listed as a beautiful and easily grown alpine, late blooming. *P. Lagáscea*, Willk. (*Lychnis Lagáscea*, Hook. f.). Low and tufted, glabrous and glaucous, 2-4 in. high: st. densely distichous, leafy below: lowest lvs. linear and obtuse, middle ones ovate-lanceolate, subacute: fls. pale rose with white center, about $\frac{3}{8}$ in. across, with 2 white acute scales at base, slightly notched at apex. B.M. 5746.—A charming plant.

L. H. B.

PETRÓPHYES: *Monanthes*. *P. muralis*, Webb=*Monanthes muralis*, Hook. f., which equals *M. atlantica*.

PETRÓPHYTUM (*petros*, rock, and *phyton*, plant; alluding to its habitat). *Rosaceæ*. A genus of 5 caespitose undershrubs with prostrate branches in W. N. Amer., allied to *Spiræa*, but differing in its follicles being dehiscent on both sutures and in its habit: lvs. crowded,

spatulate or oblanceolate, entire: fls. in terminal racemes; sepals and petals 5; stamens 20; pistils 3-5, hairy, style slender, glabrous except at the base: follicles leathery, with few linear seeds. Only the following species has been intro. into cult. and is offered by several European nurseries. It is perfectly hardy and grows best in a rocky in a sunny and well-drained position between rocks; it demands limestone soil. Prop. is by division or by seeds treated like those of *spirea*, but the young seedlings are particularly impatient of too much moisture. *P. caespitosa*, Rydb. (*Spiræa caespitosa*, Nutt. *Eriogynia caespitosa*, Wats. *Luëtkea caespitosa*, Kuntze). Densely caespitose, forming flat patches: lvs. oblanceolate, obtuse or mucronate, 1-ribbed, densely silky, $\frac{1}{4}$ - $\frac{1}{2}$ in. long: fls. small, white, in dense spikes $\frac{1}{2}$ -1 $\frac{1}{4}$ in. long on upright stalks 1-4 in. long; petals spatulate, obtuse; stamens exserted. July, Aug. S. D. and Mont. to Calif. and New Mex. M.D.G. 1907:85.

ALFRED REHDER.

PETROSELĪNUM (Greek, *rock-parsley*). *Umbelliferae*. About a half-dozen European chiefly biennial herbs, one of which is cult. for its ornamental and edible herbage. Closely allied to *Carum* and *Apium*, with the former of which it is often united and from which it is chiefly distinguished by the greenish yellow fls. and broader incised lf.-segms. Lvs. ternately pinnate-compound, the segms. toothed and cut: fls. in compound umbels with few parts to the involucre and several or many parts to the involuclers, the petals with incurved points: fr. ovate and compressed, glabrous. *P. hortense*, Hoffm. (*P. sativum*, Hoffm. *Carum Petroselinum*, Benth. & Hook. f.). PARSLEY (which see). Erect, 1-3 ft.: lvs. ternate-pinnate, the lflets ovate and 3-cleft (much cut in the "curled" garden varieties), the upper ones narrower and nearly entire: fls. yellowish. Old World.—Much cult., and sometimes runs wild about plantations.

L. H. B.

PETTĒRIA (after Franz Petter, a Dalmatian botanist; died 1853). *Leguminosæ*. One species, a shrub, very similar in habit to *Laburnum*, but with the yellow fls. in upright dense racemes, terminal on leafy branchlets. It is but rarely cult., since it is less showy in bloom than *Laburnum* or many species of *Cytisus*. It is hardy as far north as Mass., and requires the same cult. as *Laburnum*, which see. If grafted, *laburnum* is to be used as a stock. This monotypic genus differs from *Laburnum* in its upright racemes, in the tubular calyx, the wings and keel being at the base adnate to the stamens, and in the sessile ovary. It is said to possess the same poisonous properties as that genus.

ramentacea, Presl (*Cytisus fragrans*, Welden, not Lam. *C. Weldenii*, Vis. *C. ramentaceus*, Sieb. *Laburnum ramentaceum*, Koch. *L. Weldenii*, Lavallée). Upright, to 6 ft.: lvs. 3-foliolate, almost glabrous or sparingly pubescent when young, on about 1-in.-long stalks; lflets cuneate, obovate to oblong, usually obtuse, $\frac{3}{4}$ -2 in. long: fls. fragrant, very short-pedicelled, in 1-3-in.-long dense racemes; calyx 3-lobed, silky; keel silky: pod linear-oblong, sparingly silky, to 1 $\frac{1}{2}$ in. long. May, June. Dalmatia, Istria. B.R. 29:40.

ALFRED REHDER.

PETŪNIA (*Petun*, South American aboriginal name, said to have been applied to tobacco). *Solanaceæ*. PETUNIA. Small herbs, grown for their showy bloom as garden annuals.

Annual or perennial, branching, viscid-pubescent, of weak or straggling growth: lvs. alternate, or opposite above, soft, entire: fls. white or purple, or in shades of reddish, on solitary, terminal or axillary peduncles; calyx deeply 5-parted, the lobes narrow or often foliaceous; corolla funnelform or salverform, the tube long and nearly or quite straight and sitting loosely in the calyx, the limb broad and normally 5-lobed, unequal or

oblique and in some species obscurely 2-lipped; stamens 5, attached in the tube, one of them sometimes sterile; ovary small, 2-celled, the style slender, the stigma dilated and sometimes obscurely 2-lobed.—There are 12 or more species of *Petunia*, mostly natives of the southern part of S. Amer. One or two grow in Mex. and

2879. *Petunia axillaris*. ($\times \frac{1}{4}$)

another (*P. parviflora*) is naturalized in the southern parts of the U. S., and is found frequently on ballast about seaports. The genus is closely allied to *Salpiglossis*, being distinguished by 5 perfect stamens, whereas that genus has 4 stamens and lvs. narrow or usually dentate or pinnatifid.

Garden petunias are small soft plants of straggling or decumbent habit, pubescent and usually more or less sticky, with large showy flowers. The colors are white to light purple, not blue, clear red, nor yellow. They are properly perennial, but are treated as annuals in cultivation. The common kinds are rather weedy in habit, but their great profusion of bloom under all conditions makes them useful and popular. They are particularly useful for massing against shrubbery, for they make a florid undergrowth with almost no care. Some of the modern improved named varieties are very choice plants. Petunias emit a powerful fragrance at nightfall, and sphinx-moths visit them.

The varieties of present-day gardens are considered to be hybrids and modifications of two-stem types. The types were white-flowered in one case and rose-violet in the other, and the flowers were small. In some of the garden strains, the flower is very broad and open, measuring 4 or 5 inches across. There are types with the flowers deeply fringed; others with star-like markings radiating from the throat and extending nearly or quite to the margin of the limb; others with full double flowers.

Petunias should begin to bloom about two or two and one-half months after sowing in the open and continue profusely till killed by hard frost (the first light frosts usually do not injure them). The plants are at first erect, but soon begin to sprawl. The highest blooms of mature but sprawled plants will stand 18 to 24 inches above the ground. There are very dwarf and compact kinds, but they are not much seen in this country.

Varieties or strains naturally fall into the small-flowered and large-flowered classes. The former are singles and are mostly used for bedding or massing. Some of the small lilac-limbed kinds are apparently very closely related to the stem-species, *P. violacea*, possibly direct derivatives of it. Countess of Ellesmere, Rosy Morn, and similar ones are among the best rosy or pink kinds for edgings and hanging-baskets and window-boxes. Large-flowered petunias are double or single,

fringed, ruffled, fluted, and otherwise modified, some of them having deep velvety colors of great richness and flowers of much substance. There are marbled, spotted, and penciled flowers among them.

Double forms are produced by crossing the most double flowers that are capable of producing good pollen on the best single strains. Only a part of the seedlings produce doubles, but all the others are likely to produce superior semi-double and single forms. Single flowers carefully pollinated from double flowers will produce seed which will average 25 per cent doubles, and single flowers bearing petaloid anthers similarly pollinated will give an average as high as 40 per cent doubles. The weaker seedlings are most likely to give full double flowers.

Petunias thrive on both ordinary and rich soil, blooming well on land too rich for other plants, and some of the bedding and small kinds doing well even on poor soil with plenty of moisture. They are sun-loving plants, although they bloom well in partial shade. The culture is simple and easy. Seeds may be sown directly in the open, or the plants may be started in flats or pots indoors for early results. The plants are tender and therefore should not be trusted in the open until settled weather comes. The high-bred types require more care in the growing. They would best be started indoors, and be given the choicest positions in the open garden. Extra care should be given to the germination, for every seed that is lost may mean the loss of a form unlike any other; for these high-class petunias are not fixed into definite seed-varieties to any extent. Usually the weakest plants in the lot of seedlings will produce the choicest results among the high-bred single and double strains, the strongest seedlings tending to make weedy plants. Transplanting is recommended for the high-bred fringed and double strains, as well as for early bloom. The seeds are small and should be covered lightly in well-pulverized soil. On ordinary soil, petunias may be thinned or transplanted to 10 or 12

2880. *Petunia hybrida*. ($\times \frac{3}{4}$)

inches apart each way; but on fertile soil, and particularly with the larger-growing forms, the distance may be as much as 15 to 18 inches. Young petunia plants are very susceptible to frost. It is well to pull out some of the least desirable plants as they grow and begin to crowd. The stronger common strains of petunia are likely to self-sow or volunteer (come up themselves in the spring from seed). Fancy kinds are sometimes propagated by cuttings or slips from plants carried over winter, after the manner of geraniums. The best double strains particularly are often perpetuated by cuttings. There are no special insects or diseases attacking the petunia.

Winter bloom is easy to secure from petunias under glass. Best, or at least quickest, results are secured from cuttings; these may be taken from good shoots in late September or early October from selected outdoor plants, and bloom should be secured by February 1. If plants are grown from seeds, the sowing should take place in late summer, for seedlings grow slowly in the short days of fall and winter; the seedlings should be handled in pots. Sometimes old plants that are not spent are lifted in the fall and cut back, and the new growth will give good winter bloom. Petunias under glass require cool treatment, a night temperature of 45° to 50° suiting them well. A somewhat warmer treatment than that given carnations may be expected to produce satisfactory results.

axillaris, BSP. (*P. nyctaginiflora*, Juss. *Nicotiana axillaris*, Lam.). Fig. 2879. LARGE WHITE PETUNIA. Tall and relatively stout, usually growing erect; lvs. large and rather thick, oval-oblong, upper ones nearly or quite sessile and the lower ones narrowed into a distinct petiole: fls. dull white, long-tubed (the tube 3 or 4 times the length of the calyx), fragrant at evening. Argentina. B.M. 2552.—Frequently seen in old gardens, and also escaped.

violacea, Lindl. VIOLET-FLOWERED PETUNIA. Sts. slender: lvs. oval or ovate, sessile or very short-stalked: fls. smaller, broad-tubed (the tube twice or less the length of the linear calyx-lobes, rose-red or violet, the limb relatively short. Argentina. B.R. 1626. B.M. 3113 (as *Salpiglossis integrifolia*).—This species, or its garden derivatives, sometimes runs wild from gardens.

hybrida, Hort. Figs. 2880-2882. Common petunia, probably a hybrid derivative of the two preceding. For history, see Bailey, "Survival of the Unlike." P.M. 2: 173 (as *P. nyctaginiflora violacea*). B.M. 3556.—This type is remarkably variable, but it differs markedly from either parent: from *P. axillaris* in its broader tube and many colors; from *P. violacea* in its longer tube, wider limb, and many colors; from both in its much larger and multiform fls. and more stocky growth. In some of the strains, the fl. is very broad and open, measuring 4 or 5 in. across. There are types

with the fls. deeply fringed; others with star-like markings radiating from the throat and extending nearly or quite to the margin of the limb; others with full double fls. The colors range from white to deep red-purple, and variously striped and barred. There are forms of very dwarf and compact habit.

L. H. B.

2882. A modern race of fringed petunia. ($\times \frac{1}{4}$)

PEUCEDANUM (ancient Greek name). *Umbelliferae*. There are many views as to the limits of the genus Peucedanum, which is equivalent to saying that it has no natural limits. Bentham & Hooker made it a most complex group, comprising about one hundred Old World and New World species, and including such genera as *Petroselinum*, *Anethum*, *Imperatoria*, *Polycyrtus*, *Tommasinia*, *Pastinaca*, *Tiedmannia*, *Lomatium*. Coulter & Rose, American monographers ("Monograph of the North American Umbelliferae," United States Department of Agriculture, 1900), remove the American species and accept Rafinesque's genus *Lomatium*, where these species may be found (page 1903, Vol. IV). The parsnip has been included in this genus as *P. sativum*, Benth. & Hook., but is here kept distinct under *Pastinaca*. Various species of Peucedanum may be transferred to grounds in Europe, or the countries where they grow, but they are not known as horticultural subjects.

PEUMUS (Chilean name). Syn., *Boldoa*, *Boldoa*, *Ruizia*. *Monimidiaceae*. The Chilean boldo, a small tree of considerable economic interest.

Evergreen tree or large shrub of 1 species, *P. Böldus*, Molina (*P. fràgrans*, Pers. *Ruizia fràgrans*, Ruiz & Pav. *Boldoa fràgrans*, Gay): dioecious: male fls. with 10-12 perianth-lobes, overlapping in 2-3 series, the outer ones herbaceous or membranous, the inner ones more petal-like; stamens numerous; female fls. smaller, the lobes more unequal, after anthesis circumscissile above the disk-bearing base and deciduous: drupes 2-5 or rarely solitary, stipitate on the receptacle; seeds pendulous: the tree attains a height of 20 ft., with lvs. opposite, leathery, very rough and warty, ovate or ovate-elliptic, short-petioled, obtuse. Chile. B.R. 31:57.—The tree has exceedingly hard wood, which is used for making many kinds of implements; it also makes a charcoal said to be prized by smiths above all others. The bark is used in tanning and dyeing. The lvs. are used in medicine. The frs. are edible; they are small berries, sweet and aromatic. Finally it has some ornamental value, being evergreen and fragrant throughout. The fls., which are not very showy, are white, $\frac{1}{2}$ in. across, and borne in small panicles, each branch of which is parted into three. It has been advertised in S. Calif.

2881. *Petunia hybrida*. A double form. ($\times \frac{1}{2}$)

The male tree has been cult. under glass in Eu., but scarcely outside of botanic gardens and for its economic interest.

L. H. B.

PFÄFFIA (C. H. Pfaff, 1774–1852, German chemist). *Amarantaceæ*. Slender perennial herbs from Trop. and extra-Trop. S. Amer., tomentose or villous, rarely glabrate: lvs. opposite, sessile or nearly so, entire: heads or spikes densely fld.; bracts and bractlets transparent: fls. usually in solitary long-peduncled heads, bracteate and with 2 bractlets; perianth 5-parted; staminal tube long, 5-cut to the middle, the anther-bearing teeth ciliate at the margin; stigma discoid or head-like, entire or 2-lobed.—Species about 20, one of which is known more or less in gardens, although it is not certain whether the plants that have been in the trade are properly named.

gnaphaloides, Mart. (*Gomphrena gnaphaloides*, Vahl). Perennial, 1 ft.: sts. subshrubby below: lvs. lanceolate, 10–15 lines long, 2–4 lines wide, soft, ashy gray above, woolly beneath: peduncles 5–7 in. long; heads globose, 6–9 lines across; bracts unequal, ovate, mucronate, scarious, the lower one villous, lateral ones longer, glabrous at the base; stigma globose. Brazil, Uruguay.—Recorded as a stove plant in England, but the plant that has been offered in this country was recommended as an outdoor perennial.

WILHELM MILLER.

PFEIFFERA (named for Ludwig Pfeiffer, a distinguished student of cactus). *Cactaceæ*. Epiphytic plants, at first erect but branches usually hanging, mostly 4-angled: areoles bearing small acicular spines: fls. regular, rose-colored, small: ovary and fr. spiny; seeds black. This genus was included in *Rhipsalis* in *Cyclo. Amer. Hort.*

ianthothèle, Web. (*Rhipsalis ianthothèle*, Web. *R. cereiformis*, Foerst. *P. cereiformis*, Salm-Dyck). Sts. pendent, 1–2 ft. long, branching, less than 1 in. diam., 4- rarely 3-angled: ribs tuberculate: areoles at summit of tubercles short-woolly, soon naked, bearing 6–7 short bristles: fls. with very short tube, but the fl. bell-shaped, purple-red without, pure white within, nearly 1 in. long, little more than half as much wide: fr. the size of a cherry, rose-red, with bristles like those of the st. Argentina.

J. N. ROSE.

PHACELIA (Greek, *cluster*; on account of the crowded flower-clusters of the first described species). *Hydrophyllaceæ*. Annual and sometimes perennial herbs, grown for the blue, purple, or white flowers.

Low or not tall plants, with alternate simple or compound lvs. and infl. in more or less scorpioid cymes or spikes: corolla deciduous as the caps. enlarges, in various shades of blue, purple, or white; tube with or without interval appendages, these when present in the form of 5 or 10 vertical folds or projections, adnate to or free from the bases of the filaments; calyx-lobes commonly narrow, often enlarged upward, especially in fr.; style more or less 2-lobed: seed-coats reticulated or pitted.—Species 114, as defined by Brand in hft. 59 (IV. 251) of Engler's "Das Pflanzenfamilien" (1913), American, mostly from W. N. Amer. The plants are hairy, nearly smooth, or glandular in whole or in part. The herbage of some of the glandular-hairy species has an offensive odor.

The genus includes the old genera *Whitlavia*, *Eutoca*, *Microgenetes*, *Cosmanthus*, and others. The flowers are mainly of a handsome blue or violet, many species and varieties running through lighter shades to pure white, but not to yellow. The annuals are of easy cultivation, requiring, to bring them to perfection, a soil warm, sunny, and not too moist. Some species like a sandy soil, others a firmer clay. Some are erect and give the best effects when planted thickly; others are more spreading and therefore require considerable space. In

height they vary from only a few inches to 2 to 3 feet. The flowers are borne on more or less recurved racemes that straighten as the flowering proceeds. They vary from 1 inch long in some species to less than $\frac{1}{4}$ inch in others. In addition to those described below there are many other beautiful species of *phacelia* that should be in the trade. The species best known in cultivation is *P. Whitlavia*, a garden annual known as *whitlavia*.

A. Seeds transversely corrugated, not pitted or reticulated as in the other sections.

1. *Orcuttiana*, Gray. Viscid, puberulent, about 1 ft. high: lvs. pinnatifid, somewhat lyrate, the lobes short-oblong and entire: fls. sessile in the at length elongated dense spikes; corolla rotate—campanulate, double the length of the calyx, with limb 3–4 lines broad, white, with yellow eye, nearly or quite destitute of internal appendages: caps. oval, nearly equaling the narrowly spatulate (barely 2 lines long) sepals, 12–14-seeded; seeds oval, obscurely favose-reticulated between the transverse corrugations. Low. Calif.

AA. Seeds pitted, punctate or reticulated.

B. Corolla without internal appendages.

2. *fimbriata*, Michx. (*Cosmanthus fimbriatus*, Mey.). Weak and diffuse annual, a span high, somewhat hirsute: cauline lvs. 3–7-cleft or -lobed or

the lower lyrate divided, the lobes obtuse or roundish: racemes few-fld.; pedicels filiform; calyx-lobes linear-oblong or spatulate; corolla white, only 3–4 lines broad, shorter than the stamens, its lobes fimbriate. Alleghany Mts., Va. to Ala.; April, May.

3. *viscida*, Torr. (*Eutoca viscida*, Benth.). Fig. 2883. Annual, a foot or 2 high, branching, hirsute at base, very glandular above: lvs. ovate or obscurely cordate, doubly or incisely and irregularly dentate, 1–3 in. long: corolla deep blue, with purple or whitish center, from half to nearly an inch in diam. S. Calif. B.M. 3572. B.R. 1808. R.H. 1851:361. J.H. III. 29:183; 48:302. Var. *albiflora*, Gray. Fls. white.

BB. Corolla bearing internal appendages.

c. Appendages 5, small and truncate or emarginate and attached to the base of each filament.

4. *Whitlavia*, Gray (*Whitlavia grandiflora*, Harv.). **WHITLAVIA. CALIFORNIA BLUEBELL.** Fig. 2884. An attractive and variable easily grown annual, about 1–1½ ft. high, loosely branching, hirsute and glandular: lvs. ovate or deltoid, incisely toothed: corolla with cylindrical-ventricose tube usually an inch long, thence

2883. *Phacelia viscida*. ($\times \frac{1}{2}$)

the length of the lobes; appendages to the filaments hairy. S. Calif. B.M. 4813. F.S. 11:1085. G.C. 1854: 679.—A beautiful species and much cult., with fls. an inch long and nearly as wide; sometimes escaped in Eu. Var. *gloxinioides*, Voss (*Whitlavia gloxinioides*, Hort.), has handsome white fls. with blue center. Var. *álba*, Hort. (*Whitlavia álba*, Hort.), is white-fl.

5. *Párryi*, Torr. Annual, rather slender, 9–18 in. high: lvs. ovate, irregularly and incisely double-toothed or lacinate, or the lowest sometimes pinnately parted; the upper cauline longer than their petioles: corolla cleft beyond the middle, deep violet, 8 lines across; filaments bearded: ovules on each placenta 20–30; seeds 15–20. Calif. B.M. 6842. G.C. II. 24:716. Gt. 34:1207.

6. *campanulària*, Gray. Annual, lower than the last: lvs. subcordate or cordate, less deeply dentate: tube of the truly campanulate corolla $\frac{1}{2}$ in. long, expanded at throat, barely twice the length of the lobes; appendages to the filaments glabrous and smaller, otherwise much like No. 4 and almost as showy. S. Calif. B.M. 6735. G.C. II. 20:135; III. 55:173. F. 1883:145. Gn. 31, p. 554; 55:36.—*P. campanulàta*, Hort., is presumably this plant.

cc. Appendages in corolla 10.

d. Ovules numerous, or more than 2, on each placenta

7. *lineàris*, Holz. (*Hydrophýllum lineàre*, Pursh. *Eutoca Méneziesii*, R. Br. *P. Méneziesii*, Torr. *Eutoca multiflora*, Douglas). Annual and perhaps perennial, 9–12 in. high, at length paniculate-branched, hispid or roughish hirsute, usually also minutely cinereous-pubescent: lvs. mostly sessile, linear or lanceolate, entire or a few of them deeply cleft, with few or single linear or lanceolate entire lobes: spikes or spike-like racemes thyrsoid-paniculate, at length elongated and erect; corolla bright violet or sometimes white; ovules 12–16: caps. shorter than the calyx; seeds oblong, coarsely favose-reticulated. Calif. to Wash., and east to Mont. and Utah. B.R. 1180. B.M. 3762.—A beautiful species, and easily cult.

8. *divaricàta*, Gray (*Eutoca divaricàta*, Benth. *E. mexicana*, Hort.). Diffusely spreading annual, a span high, more or less hirsute and pubescent: lvs. ovate or oblong, mostly longer than the petiole, sometimes 1–2-toothed or lobed at base, the rims curving upward: spikes or racemes at length loose; the pedicels usually

much shorter than the calyx; style 2-cleft at apex: ovules 12–20 on each placenta. Calif. B.M. 3706. B.R. 1784. Var. *Wrangeliana*, A. DC. Fig. 2885. Differs from the type in having the lvs. inclined to be lobed or 1–2-toothed. It is known to the trade as *Eutoca Wrangeliana*, Fisch. & Mey. P.M. 5:199.

2885. *Phacelia divaricata* var. *Wrangeliana*. ($\times \frac{1}{2}$)

dd. Ovules only 2 on each placenta.

e. Lvs. all simple and entire (except perhaps the lowest).

9. *hùmilis*, Torr. & Gray. Annual, unbranched or branched from the base, 2–6 in. high, pubescent or infl. often hirsute: lvs. spatulate, oblong or oblanceolate, generally obtuse, the lower rarely with 1–2 ascending lobes: spikes loosely paniculate or solitary; corolla indigo-blue, rather deeply lobed, surpassing the usually linear calyx-lobes; filaments moderately exserted, glabrous or sparingly bearded above. Calif. to Wash.—A pretty little plant.

ee. Lvs. oblong or narrower, pinnately toothed to compound.

10. *bipinnatífida*, Michx. Biennial, erect, branched, 1–2 ft., viscid above: lvs. with slender petioles, to 5 in. long, pinnatifid, with 3–7 ovate or oblong dentate or pinnatifid segms.: fls. violet or blue, $\frac{1}{2}$ in. or more broad, in loose racemes which are little scirpioid; calyx-lobes linear; corolla rotate-campanulate with conspicuous ciliate appendages in pairs between the stamens. N. C. to Mo. and south.

11. *glandulòsa*, Nutt. (*Eutoca glandulòsa*, Hook.). Viscid-pubescent and glandular annual, softly if at all hirsute, 9–12 in. or more high: lvs. irregularly and interruptedly 2-pinnatifid, or below divided; the numerous lobes oblong, small, somewhat incised, obtuse: calyx-lobes oblong or spatulate; corolla about 2 lines long, bluish, purplish or white, with lobes shorter than the tube; stamens and 2-cleft style moderately or conspicuously exserted: seeds with the minute reticulations even. Texas to Ariz. and north to Mont.

2884. *Phacelia Whitlavia*. ($\times \frac{1}{2}$)

12. *congéstá*, Hook. (*P. conférta*, Don). Pubescent and commonly cinereous erect annual, hardly viscid or glandular in the least, a foot or more high: lvs. pinnately 3-7-divided or -parted, and with a few interposed small lobes, the main divisions oblong or oval, incisely pinnatifid or irregularly lobed, the lower ones mostly petiolate and the upper confluent: calyx-lobes linear or somewhat spatulate; corolla blue, 3 lines long, the lobes as long as the tube; stamens more or less exserted: seeds reticulate scabrous, the fine sharp meshes being, as it were, toothed at the junctions. Texas, New Mex. B.M. 3452. V. 5:154; 12:140.

13. *tanacetifolia*, Benth. (*P. tripinnata*, Hort.). Erect annual, often cult., roughish hirsute or hispid, not glandular, or above slightly so, 1-3 ft. high: lvs. pinnately 9-17-divided into linear or oblong-linear once or twice pinnately parted or cleft divisions, all sessile or nearly so, the lobes mostly linear-oblong: spikes cymosely clustered, at length elongated: very short fruiting pedicels ascending or erect: calyx-lobes linear or linear-spatulate, not twice the length of the ellipsoidal caps.; stamens and style conspicuously exserted: seeds with very narrow pits bounded by thick walls. Calif. B.M. 3703. B.R. 1696.—Said to be sometimes cult. as a bee-plant. According to Jepson, "Cows fed on it show a marked increase in yield of milk but will not eat it alone at first." Variable. Var. *álba*, Hort., has been offered.

L. F. HENDERSON.
L. H. B.†

PHÆDRANÁSSA (Greek, *gay queen*, suggested by the beauty of the flowers). *Amaryllidaceæ*. Tender mostly summer-blooming bulbs, with flowers that are tubular in appearance, borne in umbels, generally drooping and usually bright red with green tips.

Bulb tunicated: fls. on a peduncle or scape 10 in. to 2 or 3 ft. long; perianth subcylindrical; segms. 6, equal, regular, spreading only at the tip; stamens inserted at or below the throat of the tube; ovary 3-celled; ovules many, superposed: caps. globose, loculicidally 3-valved; seeds many, small, black: lvs. petioled, oblong or lanceolate, produced after the fls. according to Baker, but this point is doubtful for all species.—Species 4 or 5, in the Andes at 7,000-12,000 ft., except *P. Carmioli*, a native of Costa Rica, which differs from all other species in having the perianth-segms. much shorter than the tube. Probably the choicest species is *P. chloracra*, the tube of which seems at first sight over 2 in. long; however, the segms. are merely connivent and it is only for a distance of $\frac{1}{2}$ in. at the base that they are really grown together into a tube. This species has 6-12 fls. in an umbel. *P. gloriosa*, Hort., recommended by some dealers, seems to be unknown to botanists. The species are kept rather dry in winter, and bloomed in the open or perhaps under glass in spring, summer, or autumn; prop. by offsets. They apparently thrive under the treatment afforded by a cool greenhouse.

A. Tube of perianth much shorter than the segms.

B. Fls. chiefly red.

chloracra, Herb. (*P. obtusa*, Herb. *Crinum quitense*, Spreng.). Bulb globose, 2-3 in. thick: lvs. produced after the fls.; blade 8-12 in. long, 2-3 in. wide, oblong-lanceolate and acute, the petiole clasping: peduncle 2-3 ft. long, nearly terete, glaucous; fls. scarlet, tipped green, 6-12 in the umbel, usually drooping, $1\frac{1}{2}$ -2 in. long. Andes of Ecuador, to 12,000 ft. B.M. 5361. B.R. 31:17.—The name is sometimes erroneously written *P. chloracea*.

BB. Fls. chiefly green.

viridiflora, Baker. Bulb ovoid, $1\frac{1}{2}$ in. thick: lf. solitary, bright green, lanceolate, nearly 1 ft. long; petiole short: peduncle 1 ft. long, terete; fls. about 4 in an umbel, green toward the tip, without any red, passing into whitish toward the base, drooping, the

perianth-limb $1\frac{1}{4}$ - $1\frac{1}{2}$ in. long. Andes of Ecuador.—Possibly a color variety of *P. chloracra*.

AA. Tube of perianth much longer than segms.

Carmioli, Baker. Bulb globose, 2-3 in. diam.: lvs. 1-2, equaling peduncle, oblong-lanceolate, acute, bright green, the petiole much shorter than blade: peduncle about 2 ft. long, terete, pale glaucous-green, bearing 8-10 fls. in an umbel; fls. with perianth-limb 2 in. long, the bright red tube cylindrical and 3 times as long as the oblong-lanceolate green pale-edged segms.; stamens exserted. Costa Rica. B.M. 8356, where it is said the plant requires complete rest after the lvs. die down. "The tall fl.-stalk precedes the lvs., which, however, develop while the plant is in flower."

WILHELM MILLER.
L. H. B.†

PHÆDRÁNTHUS (Greek for, *splendent* or *gay*, and *flower*, alluding to the brilliantly colored flowers). *Bignoniaceæ*. Ornamental vine grown for its very showy flowers and also for its handsome foliage.

Evergreen climbing shrub: lvs. opposite, with 1 pair of entire lfts., the terminal lft. usually replaced by a 3-parted or repeatedly 3-parted tendril: fls. in terminal racemes; calyx campanulate, 5-10-nerved, leathery, tomentose, with 5 unequal short teeth; corolla tubular-funnelform, curved; stamens slightly exserted; disk annular, raised; ovary ovoid, tomentose, with many ovules in several rows.—One species in Mex. Formerly usually referred to *Bignonia*, from which it differs chiefly in the slender filiform tendrils, the leathery tomentose calyx, the exserted stamens and tomentose ovary.—A very handsome strong-growing vine for subtropical regions or in the N. for the cool greenhouse; one of the most showy bignoniads on account of its large brilliantly colored fls. For cult. and prop., see *Bignonia*.

buccinatórius, Miers (*Bignonia Cherère*, Lindl. *B. Kerère*, Hort., not Aubl. *B. buccinatória*, Mairet). Tall tendril-climber; branches obtusely angled: lfts. 2, or sometimes 3, elliptic to ovate-oblong, cuspidate or obtuse, thinly coriaceous, glabrous and lustrous above, tomentose beneath while young, later hairy only on the veins, glandular, 2-3 in. long: fls. pendulous, in terminal racemes with erect stout and short rachis; calyx $\frac{1}{2}$ in. long; corolla 4 in. long, blood-red, yellow at the base, lobes spreading, emarginate, about $\frac{1}{2}$ in. long. Summer. Mex. B.M. 7516. Gn. 26:520. B.R. 1301. R.H. 1898:580.

ALFRED REIDER.

PHÆNÓCOMA (*shining hair*, Greek, alluding to the involucre). *Compositæ*. A South African little shrub, sometimes grown under glass for the showy flower-heads.

Of the *Gnaphalium-Helipterum-Helichrysum* relation, one species: heads heterogamous, very many-fld., showy because of the brilliant and elongated inner scales of the involucre; florets all tubular and 5-toothed, the marginal female and in a single row, the others male with abortive stigma; receptacle naked; pappus of many rough bristles in a single row, equaling the corolla, somewhat unlike as between the female and male fls. The stiff parts of the involucre make it useful as an everlasting, for which use it is a very showy subject.

These are handsome and distinct evergreen plants. They need a cool airy and shaded house during the summer. They should have plenty of ventilation in the spring and well into the autumn; this will tend greatly to solidify the growth, this causing the greater production of flowers. It is better to place the pots on screened coal-ashes, as this helps to keep the roots cool and moist. They are better if kept by themselves, as they should not be syringed. Watering is a matter of great importance at all seasons. They need some staking and tying so as to keep them in shape. When the weather is cool enough, they should have a temperature

of 45° to 50° at night, with about 10° rise with sunshine. In midwinter the temperature may drop to 40° at night. Any repotting may be done after they are through flowering. Compost used for potting these plants should be loam and fibrous peat in equal parts, left lumpy, and about one-third of silver sand added to the mixture. Give the pots thorough drainage.—They may be increased from cuttings made of the points of some of the moderately strong growths, leaving them about 3 inches long. Place in pans filled with sand. Give them a temperature of about 55°, keeping them moderately close, shaded, and moist. When they show signs of root-formation they may be given more light. When rooted, pot off into small pots using the compost mentioned above, and by shifting and the same culture they grow into good plants in two years. When they get into 8- or 10-inch pots, with plenty of roots, they may have liquid feeding which will help to retain their vigor. These plants are not much seen in this country, but should be more grown. (J. J. M. Farrell.)

prolifera, Don (*Xeranthemum proliferum*, Linn. *Helichrysum proliferum*, Willd.). An old cult. plant, now little grown: sts. woody, 1-2 ft. high, much branched, short side-branchlets tomentose and with minute closely imbricated scale-like lvs., on the main sts. the lvs. acuminate, rigid, and deciduous: heads terminal, solitary, 1-1½ in. across; involucre with many rows of woolly-based scales, the inner ones being rosy purple as if rays and lanceolate-acuminate. Mountains in the Cape region. B.M. 2365. B.R. 21. Var. **Barnesii**, Hort., has heads of deep crimson.

L. H. B.

PHÆOMÈRIA (Greek, *dark* and *part*). *Zingiberaceæ*. Perennial herbs from a thick rhizome, grown in the hothouse for their foliage and fls. Flowering sts. separate from the leafy ones; the latter not rarely tall, sometimes gigantic and forming very dense reed-like thickets; the former everywhere smaller although sometimes about 3 ft.: lvs. distichous, often numerous, rather large, provided with a commonly leathery ligule: fls. sessile, in spikes or heads, often large or very large, either broad-pyramidal or subglobose, rarely concave at the top, surrounded commonly by a rather large involucre composed of colored bracts, the flowering bracts smaller and less intensely colored; calyx tubular or subclavate, frequently deeply split on one side, often very short-acuminate or not at all lobulate at the top; corolla-tube narrowly cylindrical, dilated toward the top; the lobes narrow, subspatulate, subequal: caps. or rather berries massed together somewhat resembling a pineapple.—About 16 species. Ceylon, to New Guinea. *Phæomeria* was formerly included in *Amomum* but is now considered a distinct genus. *P. magnifica*, Schumann (*Alpinia magnifica*, Roscoe. *Amomum magnificum*, Benth. & Hook. f.), is described under *Amomum*. See Vol. I, p. 275.

F. TRACY HUBBARD.

PHÆONEÛRON (Greek, *dark nerve*). *Melastomaceæ*. Half shrubby or perennial herbs: lvs. opposite, the opposed pair often differing in size: fls. 5-ranked, medium-sized; calyx obovate, margin entire and not crenate; corolla broad-oval, rather acute; stamens 10, equal or subequal; anther rather thick, linear, connective drawn out behind in a thick almost quadrangular appendage and provided in front with 2 fleshy ball-likeickenings; pistil twice as long as the stamens; ovary 5-celled, the lower half joined to the calyx-tube by the septæ: fr. a fragile apparently unevenly bursting caps.; seeds numerous.—About 4 species, Trop. Afr. *P. Moldenkei*, Stapf. St. herbaceous, terete: branches obtusely petragonous: petioles and panicles covered with purple urfuraceous pubescence: lvs. 4-6 in. long, ovate or elliptic-ovate, subacuminate, base rounded or subcordate, 5-7-nerved: infl. terminal, lax-fld.; fls. short-bedicelled; calyx hemispheric, mouth truncate, entire;

petals obliquely obovate, pale rose-purple within: fr. a globose berry; seeds rhombic-cuneiform, numerous. W. Afr. B.M. 7729.—A tropical house plant cult. sparingly in botanic gardens.

F. TRACY HUBBARD.

PHAIOCALÁNTHE (compounded from *Phaius* and *Calanthe*). *Orchidaceæ*. A group of orchids established to contain the hybrids between *Phaius* and *Calanthe*. *Pc. Colmanii* (C. Regnier Stevensii × P. Norman).—*Pc. Cooksonii*. J.H. III. 68:443.—*Pc. grandis* (C. Bryan × P. grandifolius).—*Pc. Schroederiana* (C. gigas × P. Wallichii). Sepals and petals lilac, the lip claret-colored. G.M. 44:387.—*Pc. Sedemiana* (C. Veitchii × P. grandifolius). Sepals and petals delicate primrose, flushed at base with pale rose, the lip pale primrose, bright yellow at base and on keels, the lobes flushed with rose

PHAIOCYMBÍDIUM (compounded from *Phaius* and *Cymbidium*). *Orchidaceæ*. A group established to contain hybrids between *Phaius* and *Cymbidium*. *P. chardivarënsis* = *P. grandifolius* × *C. giganteum*.

PHAIUS (Greek, *dark*; referring to the color of the flowers). Often spelled *Phajus*. *Orchidaceæ*. Very large orchids with ample foliage and tall clustered stems terminating in racemes of showy flowers.

Sepals and petals similar, spreading or half-spreading; labellum large, with the lateral lobes inclosing the column, usually gibbous or spurred behind; column slender; pollinia 8. Distinguished from *Calanthe* by the free labellum; from *Thunia* by the leafless bracted scape which does not terminate the leafy axis.—About 20 species, natives of Trop. Asia, Afr., Austral., China, Japan, and the South Sea Isls.

The genus *Phaius* includes both epiphytic and terrestrial representatives. The noteworthy epiphytic types are native of Madagascar, including *P. tuberculatus*, *P. simulans*, and *P. Humblotii*. However they are not frequently represented in orchid collections. They enjoy a warm moist atmosphere as for *vanda*. The potting medium should include chopped peat and moss in equal proportion. When potting, small rafts with the potting medium packed around or sections of fern stems, the latter being preferable, should be placed in the center of the pot or basket. The terrestrial species, especially *P. grandifolius*, are well known, being one of the first orchids put under cultivation. It dates as far back as 1778, when it was imported from China. Various species are native to low-lying swampy places of tropical Asia and Australia, and have also become naturalized in the West Indies. They are of easy culture and will grow in an ordinary warmhouse associated with palms. They delight in moisture throughout the year, in a growing medium of sandy fibrous sod-soil, with plenty of organic fertilizer in a dried state mixed with the soil and also in liquid form when in full growth. The main factor to bear in mind is perfect drainage. Plants are increased readily by the division of the dormant pseudobulbs. Upward of thirty garden hybrids are under cultivation at the present time, including some interesting bigeneric forms. (G. H. Pring.)

A. Fls. yellow to brown.

maculatus, Lindl. Pseudobulbs ovate, 2-5 in. high: lvs. 3-4, broadly lanceolate, plicate, 1½-2 ft. long, variegated with numerous yellowish spots: fl.-sts. about 2 ft. high, bearing a raceme of 10-15 yellow fls. each 2-3 in. diam.; sepals and petals half spreading, oblong, obtuse; labellum erect, with the apex recurved, streaked with orange, wavy and crenate, sides convolute over the column, and the base prolonged into a spur half as long as the ovary. Spring. N. India and Japan. B.M. 2719 (as *Bletia Woodfordii*); 3960. L.B.C. 19:1803.—A good spring bloomer.

Wallichii, Lindl. (*P. bicolor*, Lindl. *P. grandifolius*, Lindl., not Lour. *P. grandiflorus*, Reichb. f.). Fig. 2886. Tall: lvs. broadly elliptic-lanceolate, 3-4 ft. long; fl.-sts. erect, 3-5 ft. high, clothed with scales: fls. 4 in. across, varying in color from chocolate-brown to primrose-yellow; sepals and petals spreading, lanceolate, long-acuminate; labellum with an ample elongate tube; limb oblong, acute or acuminate, recurved, margin

2886. Outline of *Phaius Wallichii*. ($\times$ nearly $\frac{1}{2}$)
To show botanical structure.

crisp; spur slender, incurved. The labellum is less variable in color than the sepals and petals. The base of the tube is yellow, dull reddish beyond, with the throat purple with yellow or red edges on the disk; apex white. Feb.-May. Trop. India, northward to the lower Himalaya. B.M. 4078; 7023. P.M. 6:193. Var. *flavescens*, Hort. Sepals and petals light yellow, front of lip paler.—*P. Blumei*, Lindl., is not very clearly distinguished by botanical characters: the sepals and petals are acuminate, tip of lip acute, spur short and thick. Ceylon.

grandifolius, Lour. (*Blëtia Tánkervillæ*, R. Br.). One of the oldest orchids in cult. It has smaller fls. than *P. Wallichii*, with less acuminate sepals and petals and a shorter obtuse lip and spur; sepals and petals reddish brown, but variable, white on the outside; labellum white at the apex, throat and disk yellow, sides crimson. China, Austral. B.M. 1924. F.S. 7:738. L.B.C. 1:20. G.C. 1872:733; II. 18:565; III. 2:112. Gn. 3, pp. 183, 221. A.G. 20:279.

AA. Fls. white to rose-color.

Humboldtii, Reichb. f. Pseudobulbs, lvs. and habit like *P. grandifolius* but smaller: fl.-st. 18-20 in. high, erect: fls. white and rose-colored, tinged and streaked with darker red; sepals oblong-acute; petals twice as wide; labellum spurless, lateral lobes striped with brown on a whitish ground, middle lobe light purple, with a yellow callus. Spring. Madagascar. R.H. 1891:204. G.C. II. 26:173. A.G. 12:161. A.F. 6:609.

tuberculösus, Blume. Rhizome thick: pseudobulbs small, bearing several lanceolate lvs. 6-9 in. long: fls. 2-3 in. across, in erect spikes; sepals and petals ovate-oblong, white; lateral lobes of the labellum recurved, yellow, almost covered with brownish crimson spots, margin crenately lobed; middle lobe bifid, white, spotted with purple, having 3 thick, yellow keels; mar-

gin crisp and crenate. Feb. Madagascar. B.M. 7307. R.B. 18:145. G.C. II. 15:341; 18:565; 21:520; III. 13:237; 29:77. G.M. 44:144. Gn. 67:294.—Difficult to grow, requiring a higher temperature than the other species.

mishmënsis, Reichb. f. St. 2-3 ft. high, leafy above: lvs. 6-10 in. long, elliptic-lanceolate, plicate: scape from the axils of the lower lvs., together with the loose raceme about 2 ft. long; fls. 2 in. across, pale or dark rose-colored; sepals linear-oblong, acuminate; petals narrower; labellum with rounded side lobes and a subquadrate, spotted middle lobe, which is somewhat 3-parted; spur slender, yellow. Himalayas. B.M. 7479.

P. amboinënsis, Blume. Fls. white, with some veining on the lip. Malaya.—*P. Ashworthianus*, Sander. A garden hybrid (*P. Mannii* $\times$ *P. maculatus*). Fls. large; sepals and petals clear old gold; labellum large, of the same color, with many radiating chocolate lines, outer surface clear yellow. G.M. 40:551.—*P. caldus*, Lindl. (*Geodorum plicatum*, Voigt). Resembling *P. grandifolius* in habit: sepals and petals dull reddish brown; lip white with tinge of pink, dark purple spot beneath, with yellow on the 2-lobed spur. Malaya.—*P. Châpmannii*—*P. Humboldtii* $\times$ *P. Phoebe*. G.M. 46:593.—*P. Cooksonii* (*P. grandifolius* $\times$ *P. Humboldtii*). Sepals and petals nankeen-green, the broad frilled tip yellow at the base with purple-brown markings, the front lobe rose. J.H. III. 46:353.—*P. Cooksonii*—*P. simulans* $\times$ *P. Wallichii*. G.M. 50:134.—*P. Cooperi*, Rolfe. Sepals and petals bright red-brown in front, pale yellow behind, about 2 in. long; lip funnel-shaped, white at first, soon changing to yellow.—*P. fragrans*, Hort. Belonging to same group as *P. tuberculösus*, but fls. smaller and more numerous, in color resembling *P. Humboldtii*.—*P. Märtha* (*P. Blumei* $\times$ *P. simulans*). Fls. nankeen-yellow, the base of the lip with rose markings and veined light yellow, the front lobe tinged pink. Gt. 53:1530. R.B. 29:73.—*Norman* (*P. Sanderianus* $\times$ *P. tuberculösus*). Sepals and petals cream to pink, lined, the lip with a reddish purple base, veined yellow and with 3 yellow keels, the midlobe rose, blotched purple and tipped white.—*P. oakwoodiënsis* = *P. Cooksonii* $\times$ *P. Humboldtii*. G. C. III. 28:93.—*P. Opizi* (*P. Wallichii* $\times$ *P. Humboldtii*).—*P. Sanderianus*, Hort. Fls. 6 in. wide or more, the sepals and petals copper-red, the lip with a yellow base, crimson center, and white midlobe.—*P. schneobrunnënsis* = *P. grandifolius* $\times$ *P. assamicus*—*P. simulans*, Rolfe. "The epiphytal species known in gardens under the name of *P. tuberculösus* is not the original plant, and has been renamed *P. simulans* in allusion to the remarkable resemblance which its fls. bear to those of the original species."

GEORGE V. NASH.†

PHALACRÆA CÆLESTINA, Regel: *Ageratum conyzoides*.

PHALÆNOPSIS (Greek, *moth-like*; suggested by the large white flowers of some species). *Orchidaceæ*. This genus, called by Lindley "the grandest of all orchids," contains some of the most useful species to be found in the orchid family; greenhouse.

Of monopodial growth, having short sts. which increase slowly in length: lvs. few, thick, leathery, often mottled: infl. a raceme or panicle, large, or not longer than the lvs.; sepals spreading, the lateral ones more or less united with the base of the column; petals about as large as the sepals or very much broader; labellum variously shaped but united with the base of the column.—About 50 species natives of the hot regions of India and the Malay Archipelago, growing on trunks of trees and sides of rocks under conditions of high temperature and great moisture. The fls. are remarkably beautiful in form and color. Those of the larger species are borne in graceful drooping panicles on which they usually all face in one direction.

As all phalænopsis are natives of the most tropical regions of the globe, it is essential that they be well supplied with heat and moisture, particularly during the growing season, from March to October. Care should be taken to avoid direct draught on the plants, but air should be admitted on all possible occasions. This is absolutely necessary to keep the plants in perfect condition. During bright sunshine the plants should be shaded, but given all the light possible to insure good tough ripe foliage by autumn, and large branching flower-spikes may be expected in the flowering season. A close moist atmosphere will grow large soft foliage, but small flower-spikes usually result. Plants may be grown suspended from the roof, not too near the glass, or on benches, in pots, in baskets, in pans, or on

blocks or rafts. They are somewhat whimsical, and once a house is found in which they succeed, they should not be moved. During the growing season the temperature should be kept as uniformly as possible between 70° and 75° F., allowing a rise of 10° with sun heat. The minimum night temperature, in winter, should be 60° to 65° F. Good and ample drainage is absolutely necessary, clean potsherds and lumps of charcoal being the best material, and only sufficient peat fiber and sphagnum in equal proportions should be used to keep the plant firmly in position, as the roots will eventually cover the receptacle in which they are growing. When potting, always give the plant its natural inclination, which is invariably sufficient to prevent water remaining in the axils of the leaves, a condition which should be carefully guarded against, either from watering or from drip. Always keep the plant well raised, when potting, to insure quick and perfect drainage. Sponging the leaves occasionally will keep the plants clean and prevent the attack of thrip and red-spider. The propagation of phalænopsis is a very slow process, as the plants rarely afford opportunity for division. Sometimes young plants form on the old flower-stems, and these should be left until they make root, at which stage they may be removed, potted, and carefully watered until root-action begins in the new material. (Alfred J. Loveless.)

KEY TO THE SPECIES.

- A. Petals much broader than the sepals.
- B. Labellum with apical appendages; rostellum short.
- C. Apical appendages cirrhou.
- D. Middle lobe very narrow..... 1. amabilis
- DD. Middle lobe trowel-shaped..... 2. Aphrodite
- CC. Apical appendages short, horn-like.
- D. Lvs. green..... 3. intermedia
- DD. Lvs. mottled, at least when young.
- E. Fls. white..... 4. Stuartiana
- EE. Fls. rose-purple..... 5. Schilleriana
- BB. Labellum without apical appendages; rostellum long..... 6. Lowii
- AA. Petals scarcely or not at all broader than the sepals.
- B. Claw of the labellum with horn-like appendages below the lateral lobes... 7. Esmeralda
- BB. Claw of the labellum without appendages.
- C. Apex of the labellum notched..... 8. amethystina
- CC. Apex of the labellum entire.
- D. Rachis compressed: bracts fleshy.
- E. Middle lobe of the labellum fleshy, rounded..... 9. violacea
- EE. Middle lobe of the labellum crescent-shaped..... 10. Cornu-cervi
- DD. Rachis terete.
- E. Labellum laterally compressed, fleshy..... 11. speciosa
- EE. Labellum expanded.
- F. Middle lobe densely hairy... 12. sumatrana
- FF. Middle lobe pilose..... 13. Lueddemanniana
- FFF. Middle lobe smooth..... 14. Parishii
- G. Labellum crested..... 15. rosea
- GG. Labellum not crested, but provided with a fleshy callus..... 15. rosea

2887. *Phalænopsis amabilis*. (X ¼)

1. *amabilis*, Blume, not Lindl. (*P. grandiflora*, Lindl.). Fig. 2887. Lvs. long, pale green: fls. variable in size, sometimes about 5 in. across, pure white with stains of deep yellow and a few purple spots on the labellum and on the column; dorsal sepals ovate to oblong, lateral sepal lanceolate; petals rounded-fan-shaped; lateral lobes of the labellum obliquely cuneate, incurved, middle lobe very narrow with yellow cirrhi. Autumn. Malay Archipelago. B.M. 5184. G.C. 1848: 39; II. 26:213. Gn. 19, p. 305; 24, p. 560; 34, pp. 516, 517. R.H. 1860, pp. 238, 239; 1897, p. 151. A.G. 16:271. A.F. 27:1137; 30:610, 1079. F.E. 33:716. Gng. 15:133. Var. *aurea*, Rolfe (*P. grandiflora* var. *aurea*, Warner). Front half of the lateral lobes of the labellum and the entire middle lobe stained deep yellow. Borneo. Var. *Rimestadtiana*, Hort. Fls. larger, pure white, the throat bright yellow. G.C. III. 32:316. Gng. 12:405. P. *Hárrietta*, Rolfe, is a garden hybrid between *P. amabilis* and *P. violacea*. Fig. 2888. Fls. intermediate between the parents, 4½ in. across; sepals and petals pale yellowish white, suffused and dotted with amethyst-purple toward the base; labellum crimson with an orange crest; cirrhi slightly developed. G.C. III. 2:9. Gn. 38:156. J.H. 42:237.

2. *Aphrodite*, Reichb. f. (*P. amabilis*, Lindl., not Blume). Lvs. elliptic-lanceolate, 1 ft. or more in length, dark green, obliquely retuse: fls. 3 in. diam., pure white, with the labellum streaked and spotted with yellow and red; sepals elliptic-ovate; petals large, rhomboid; lateral lobes oblong, middle lobe trowel-shaped, with white cirrhi. Fls. at various seasons, but most freely during summer. Philippines. B.M. 4297. B.R. 24:34. P.M. 7:49. F.S. 1:40. G.C. 1848:39; II. 26:213. Gn. 31, p. 273; 35, p. 362; 38, p. 157; 48, p. 484. R.H. 1897, p. 150. A.F. 6:89. Var. *Dayana*,

Hort. (*P. amabilis* var. *Dayana*, Hort.), has regular fls. with the lower sepals minutely dotted with crimson, the labellum also being heavily marked with bright crimson. A.G. 21:457. Var. *cásta*, Rolfe (*P. cásta*, Reichb. f.). Lvs. thinly spotted; fls. like the type, with a rosy tint especially at the base of the sepals and petals, and a few spots at the base of the lateral sepals. —Scarcely distinct from the following, but distinct from the type. Var. *leucorrhôda*, Rolfe (*P. leucorrhôda*, Reichb. f.). Lvs. blotched with gray in irregular bands; sepals and petals flushed with rose, the former yellowish outside; callus yellow, spotted with purple. Philippines. F.M. 1875:166. R.H. 1896:500. Var. *Sanderiâna*, Rolfe (*P. Sanderiâna*, Reichb. f.). Fls. suffused with rose; labellum variegated with brown, purple, and yellow. Isl. of Mindanao. Gn. 24:270; 57, p. 44. Var. *gloriôsa*, Hort. (*P. gloriôsa*, Reichb. f.). Fls. white, with a rose-colored spot on the labellum. Gn. 35:362.

3. *intermèdia*, Lindl. A natural hybrid between *P. Aphrodite* and *P. rosea*. Resembles *P. Aphrodite* in habit but the fls. are smaller. Sepals oblong, acute, white; petals rhomboid, much larger, white with few rose spots at the base; labellum small, lateral lobes erect, rose-purple spotted with crimson, middle lobe rich crimson, terminating in 2 short horns. Philippines. G.C. III. 52:453. —The same type has been artificially produced by crossing the two parent species. Var. *Brymeriâna*, Reichb. f. Sepals and petals white, veined pale amethyst-purple, the lateral sepals purple-spotted at base, the petals purple-stained below; front lobe of lip red-purple. G.M. 43:63. Var. *Pôrtei*, Reichb. f. (*P. Pôrteri*, Hort.). Fls. large, stained with

16:753; III. 4:389. J.H. III. 34:157. F.E. 11:393. G. 30:195. —Very near *P. Schilleriana*, but very different in color. Var. *punctatissima*, Hort., has the sepals and petals profusely spotted with purplish red.

5. *Schilleriâna*, Reichb. f. Fig. 2889. Lvs. 6–18 in. long, oblong, dark green and mottled with gray above, purple below; panicle drooping, flat, as much as 3 ft. long and nearly as broad, bearing often over 100 fls. each $2\frac{1}{2}$ –3 in. across; dorsal sepals obovate, acute, the lateral ones ovate, rich rose-lilac; petals large, rhomboid, colored like the sepals; labellum colored like the rest of the fl. or paler and often spotted with reddish brown and having a yellow callus; lateral lobes rounded-oblong, with 2 quadrangular calli between them, middle lobe oval, ending in 2 divergent horns. Jan.–March. Philippines. B.M. 5530. F.S. 15:1559. I.H. 10:348; 35:56; 43, p. 154. S.H. 2, p. 47. Gn. 3, p. 183; 22:118; 33, p. 615; 35, p. 363; 38, p. 157; 48, p. 484. G.C. II. 12:301; III. 3:529; 17:367; 37:152. F.M. 1877:257. R.H. 1886:396. A.G. 14:65. G.F. 4:390. A.F. 11:1081. C.L.A. 6:164. F.W. 1876:321. G. 31:19. G.M. 48:151; 52:145. J.H. III. 42:451; 44:551; 52:133.

6. *Lôwii*, Reichb. f. Lvs. 4–5, oblong, fleshy, deep green, tinged with purple; panicle slender, 5–20-fld.; fls. $1\frac{1}{2}$ in. diam., white flushed with purple; dorsal sepals broadly ovate, lateral sepals oblong; petals fan-shaped, with a rounded apex; labellum violet-purple, lateral lobes small, reflexed, middle lobe oblong; rostellum very long-beaked. Flowers during summer months. Moulmein (India). B.M. 5351. F.S. 18:1910. Gn. 9:312. G.C. III. 2:745.

7. *Esmerâlda*, Reichb. f. (*P. antennifera*, Reichb.

f.). Lvs. oblong, acute, 4–8 in. long, gray-green with few dull purple spots; raceme erect, 6–10-fld., 6–18 in. high; fls. about 1 in. diam., dark or pale purple to white with red streaks; lateral sepals ovate, dorsal sepals obovate; petals obovate; labellum clawed, 3-lobed, lateral lobes ovate to rotund, erect, yellowish; middle lobe broad, obtuse, deep purple; claw with a slender appendage on each side. Cochinchina. B.M. 7196. F.M. 1879:358. R.H. 1877, p. 107.

8. *amethýstina*, Reichb. f. A small species with cuneate-oblong lvs.: fls. small, cream-colored with an amethyst labellum; sepals cuneate-oblong, obtuse; petals subequal or a little smaller; lateral lobes of the labellum cuneate; middle lobe obovate, notched. Malay. G.C. 1870:1731.

9. *violâcea*, Teijsm. & Binn. Lvs. oblong, 8–12 in. long, light shining green; fl.-stalks not longer than the lvs.: fls. few, 2 in. across; sepals and petals broadly lanceolate, yellowish white, changing to rose-violet toward the base; middle lobe of the labellum fleshy, deep purple, with a yellow callus; side lobes small, erect, purple and orange. May–Oct. Sumatra. F.M. 1879:342. G.C. II. 16:145. J.H. III. 42:537. —Plant of dwarf habit. The fls. remain on the plant a long time. Var. *Schroederiâna*, Hort., has the basal half of the segms. bright purple, the color partly broken up into lines. I.H. 32:576. J.H. III. 51:195.

10. *Cornu-cervi*, Blume & Reichb. f. Lvs. about 9 in. long, leathery, oblong; fl.-st. about as long as the lvs., erect, clavate, bearing 6–12 fls.; fls. yellowish green, barred with reddish brown; sepals and petals fleshy, lanceolate, the latter smaller; labellum whitish, lateral lobes erect on the irregular, fleshy, excavated claw, middle lobe crescent-shaped, apiculate. Summer. Trop. Asia, Java, and Sumatra. B.M. 5570 (as *Polychilos Cornu-cervi*).

11. *speciôsa*, Reichb. f. Lvs. oblong; fls. stellate, in racemes or panicles, white, blotched with rose-madder; sepals oblong; petals narrower; labellum with erect, linear, toothed, yellow side lobes, and a fleshy, purple and white middle lobe ending in a

2888. *Phalaenopsis Harriettæ*. (× about $\frac{1}{4}$)

rose-purple: lvs. about 1 ft. long, deep green. G.C. II. 5:369, 371. F.M. 1875:162. J.H. III. 30:179; 47:395. Gn. 21:146. G.M. 38:111.

4. *Stuartiâna*, Reichb. f. Lvs. elliptic-oblong, obtuse, about 1 ft. long, mottled when young, becoming dull green above and reddish below; panicle large, branched, drooping; fls. 2 in. across; sepals elliptic, obtuse, white or greenish white, the lateral ones speckled with red; petals rounded but obscurely quadrangular, white with few purple dots at base; labellum golden yellow or orange spotted with crimson, white at the tip, lateral lobes obliquely obovate, obtuse, with a pair of cuneate calli between them; middle lobe orbicular, ending in 2 white cirrhi. Jan., Feb. Philippines. B.M. 6622. I.H. 31:540. F. 1882:49. Gn. 22:118; 45, p. 426. G.C. II.

2889. *Phalaenopsis Schilleriana*. ($\times \frac{1}{4}$)

hairy cushion. Andaman Isls. (Bay of Bengal). G.C. II. 18:745; 26:277.

12. *sumatrana*, Korth. & Reichb. f. Lvs. pointed, about 6 in. long: infl. about as long as the lvs., 6-10-flid.; sepals oblong, pointed, 1 in. or more in length; petals more cuneate; all yellowish white barred, with bands of reddish brown; labellum short, clawed; lateral lobes erect, meeting and each having a short curved tooth pointing backward; middle lobe oblong, fleshy, white, streaked with violet, very hairy in front. Sumatra and Borneo. B.M. 5527. F.S. 16:1644. G.C. 1865:507.

13. *Lueddemanniæna*, Reichb. f. A small plant, with thick, oblong fleshy lvs. 6-8 in. long: infl. about as long as the lvs., with few handsome fls. near the top; fls. 2-3 in. across; sepals and petals oblong-acute, white, marked with transverse bars, those at the base being amethyst, while the upper ones are brown; labellum deep violet, with yellow blotches on the side lobes; middle lobe oblong; side lobes erect, ligulate, deeply 2-toothed. Feb., March. Philippines. B.M. 5523. F.S. 16:1636. R.H. 1872:390. F. 1865:257. G.C. III. 39:259. R.B. 26:169.—The old fl.-sts. of this plant produce young plants by which the species may be easily increased. Var. *ochracea*, Reichb. f. A form with yellowish fls. and ochre-colored bars. R.H. 1872:390.

14. *Párishii*, Reichb. f. Dwarf: lvs. oblong-lanceolate, acute, 2-4 in. long: fls. in 6-10-flid. racemes scarcely longer than the lvs., crowded; dorsal sepals oblong, lateral broadly ovate, white; petals obovate-spatulate, white; lateral lobes of the labellum small, horn-like, yellow, with purple spots, middle lobe broadly triangular, red-purple, often white on the disk; crest semi-lunar, broken up into subulate filaments in front; the disk has a peculiar appendage ending in 4 long subulate filaments. Burma and Moulmein. B.M. 5815.

15. *rosea*, Lindl. Lvs. oblong, dark green, obliquely retuse: scape about a foot long, nodding, dark purple, bearing 12-14 fls.; sepals and petals ovate, obtuse,

white, tinged with pink in the center; labellum rose-colored, scarcely longer than the sepals; lateral lobes small, lunate, middle lobe ovate. Philippines. B.M. 5212. F.S. 16:1645. G.C. 1848:671. J.F. 3:283.

P. Bértii. Natural hybrid resembling *P. amabilis*, which is one of its parents.—*P. gigantea*, J. J. Smith. Habit like that of *P. amabilis*, but lvs. larger and thicker: fls. in a raceme, whitish, with numerous brown spots. Borneo. G.C. III. 45:306.—*P. Künstleri*, Hook. f. Lvs. up to 4 in. long and 1 in. broad, bright green: raceme loosely 5-8-flid., pendulous; fls. about 2 in. across; sepals and petals similar, spreading, linear to oblong-ovate, yellow, the upper surface marked with brown; lip small, white, streaked with red. Perak. B.M. 7885.—*P. Listeri*, of doubtful authenticity.—*P. Mönnii*, Reichb. f. Fls. about 2 in. across; sepals and petals yellow, blotched and barred with brown, linear-oblong, acute; lip light yellow, the front lobe anchor-shaped, saccate at base; near the side lobes is a 2-horned slender upright plate and a purplish tooth. Assam. J.H. III. 43:97.—*P. Schilleriæno-Stuartiana*, see *P. Wiganie*.—*P. Valentini*, Reichb. f. Plant with habit of *P. violacea*: sepals purple, cuneate-oblong, the lateral ones white at base; petals like lateral sepals or purple-barred; lip short, clawed, mauve, white and yellow. Malaysia.—*P. Wiganie*—*P. Schilleriana* $\times$ *P. Stuartiana*. G.C. III. 27:83. G.M. 43:63.

HEINRICH HASSELBRING.
GEORGE V. NASH.†

PHALÆNGIUM LILIÁSTRUM: *Paradisæa*.

PHÁLARIS (old Greek name for a grass). *Graminææ*. Stout hardy ornamental grasses.

Spikelets 1-flid., in heads or spike-like panicles; glumes boat-shaped, awnless; 2 minute sterile lemmas at base of perfect floret.—Ten species, mostly of S. Eu., one native throughout the northern part of N. Amer., a variety of which is ribbon-grass. *P. canariensis*, CANARY-GRASS, which is cult. in Eu. for bird-food or as a cereal, sometimes escapes along roadsides. This annual species, on account of its variegated ovate spikes, is worthy of cult. as an ornamental grass.

arundinææa, Linn. REED CANARY-GRASS. A tall perennial (2-6 ft.), with flat $\frac{1}{2}$ in.-wide lvs. and an elongated spike-like panicle (open in anthesis) of whitish spikelets, native throughout northern Amer. in wet ground, where it is an important forage grass.—Recommended for planting in parks and grounds along the banks of streams or artificial ponds.

2890. Ribbon-grass.—*Phalaris arundinacea* var. *picta*.

Var. *picta*, Linn. (var. *variegata*, Hort.). RIBBON-GRASS. GARDENER'S GARTERS, Fig. 2890. Lvs. longitudinally striped with white. Commonly cult. for ornament and sometimes run wild about old places.

The name "*P. commutata*, or TOOWOOMBA CANARY-GRASS," has appeared in recent agricultural literature, as an intro. from Austral. The grass has been identified as *P. bulbosa*, Linn. (See Kew Bull. Misc. Inf. 1909:289).

A. S. HITCHCOCK.

PHALOCÁLLIS (Greek words referring to the delicacy of the cone formed by the crests). *Iridaceæ*. Referred by Baker and others to *Cypella*. The plant offered as *P. plumbea*, Herb., by Dutch bulb-growers is *Cypella plumbea*, Lindl., a South Brazilian species described in Volume II, page 940. B.M. 3710 (flowers chiefly lilac). F.S. 4:395 (chiefly light blue); 14:1466 (*flore striato*, veined and flushed with rich purple shades on a white ground).

PHÁRBITIS: *Ipomæa*.

PHASEOLUS (ancient Latin name, somewhat altered, of a bean). *Leguminosæ*. BEAN. The common garden and field beans, and also some species grown for ornament.

Annual or perennial mostly twining herbs, or some of them woody at the base: lvs. mostly pinnately 3-foliolate, stipellate; peduncles axillary, bearing clusters of white, yellow, red, or purplish papilionaceous fls. and more or less compressed (flat-sided) several- to many-seeded 2-valved pods. From its allied genera, *Phaseolus* is separated by minute characters of calyx, style, and keel. In *Phaseolus*, the style is bearded along the inner side and the stigma is oblique or lateral, rather than capitate on the end of the style; the keel is coiled into a spiral body, including the 10 diadelphous (9 and 1) stamens.—Many species have been described, mostly of warm countries (*P. polystachyus* is native in U. S., but not cult.), but probably not more than 150 that can be clearly separated as species.

The cultivated species of *Phaseolus* are all tropical or subtropical in nativity. Therefore they must not be subjected to frosts. Most of them are garden annuals which are planted after the danger of freezing weather has passed and the ground is well warmed. For the culture of the domesticated forms of *Phaseolus*, see

2891. *Phaseolus acutifolius* var. *latifolius*.

the article on *Bean*. See, also *Canavalia*, *Glycine*, *Mucuna*, *Soybean*, *Stizolobium*, *Vicia*, and *Vigna*.

Eleven species of *Phaseolus* are now known to be cultivated to a greater or less extent in various parts of the world. Further explorations in Mexico, Central and South America and in eastern Asia will very

probably show that a number of other distinct species not here enumerated have been domesticated locally.

The eleven species here treated fall into two groups, the one perennial, the other annual, at least in the United States.

2892. *Phaseolus multiflorus*. ($\times \frac{1}{4}$)

I. PERENNIAL BEANS.

This group includes three species, none of which is now commonly seen in cultivation.

A. Plant tall-twining, with large, fragrant, showy fls.: root not tuberous.

B. Fls. light purple to yellowish, in axillary racemes.

1. **Caracalla**, Linn. CARACOL. SNAIL-FLOWER. CORKSCREW-FLOWER. Lfts. broadly rhombic-ovate, pointed or acuminate: fls. large and fleshy, very fragrant, the large keel coiled like a snail-shell. Tropics, probably of the Old World. B.R. 341. V. 2, p. 370.—Naturalized in parts of Calif., where it grows 20 or more ft. high, sometimes becoming a nuisance. It is an old-fashioned glasshouse plant in cold climates, but is now rarely seen. *P. Bertonii*, Hort., recently intro. from Paraguay, although a close relative, is probably specifically distinct from *P. Caracalla*.

BB. Fls. red or light blue, in axillary dense capitate clusters.

2. **adenanthus**, Mey. (*P. amænus*, Soland. *P. truxillensis*, HBK. *P. cirrhosus*, HBK.). Foliage much

like that of the last, the lfts. ovate and somewhat acute: fls. very showy, red (or light blue?), fragrant: pod 4-6 in. long, usually curved. Tropics.

AA. *Plant low, spreading or trailing, annual above the ground: root tuberous: fls. small, in loose axillary, interrupted racemes.*

3. *retusus*, Benth. METCALF BEAN. Root very large and fleshy, running deep into the ground: st. roughish: lfts. rhombic to oblong, mostly obtuse and often retuse, rough on both sides, with prominent veinlets, especially beneath: fls. reddish purple: pod flat, short, broadly oblong, somewhat curved. Texas, west and south.—Lately recommended as a forage plant in the dry regions of the S. W. Not promising in Ariz. at elevations less than 4,000 ft. The lvs. are thick and heavy and adapted to dry, hot climates. Sts. grow 8-10 ft. or more long on the mountains where it is a favorite food for deer.

II. ANNUAL GARDEN BEANS.

The species of this group are all annuals with the exception that *P. multiflorus* and *P. lunatus* are perennial in tropical countries. The somewhat thickened roots of the former sometimes live over in the South, but both species are strictly annual in the northern and middle states.

A. Fls. yellow.

B. Lfts. distinctly lobed.

c. The lfts. 3-5-cut for one-fourth to one-half their length.

4. *aconitifolius*, Jacq. MOTH BEAN. A diffuse trailing plant, 1-2 ft. long with slender sts. loosely covered with rather stiff, brown hairs: lfts. 3-5-lobed at the apex for one-fourth to one-half their length, the lobes narrow; stipules small, narrow, and pointed: fls. very small, yellowish, in heads on the ends of hairy axillary peduncles: pod becoming 2 in. long, nearly cylindrical, glabrous; seeds clay-colored, cylindrical, distinctly elongated, average weight about .03 gram; hilum less than $\frac{1}{2}$ in. (2 mm.) long. India, where it is cult. for human food and

2893. Barteldes Bush Lima. Probably a form of *Phaseolus multiflorus*. ($\times \frac{1}{2}$)

2894. *Phaseolus multiflorus*. White-seeded form. ($\times \frac{1}{2}$)

for forage, but only rarely seen in collections in this country.

cc. The lfts. shallowly 3-lobed.

5. *angularis*, Willd. ADZUKI BEAN. Erect, 1-2 ft. high: sts. slightly furrowed, smooth or with scattered retuse hairs: lfts. ovate, shallowly 3-lobed, smooth or slightly roughened with scattered hairs: fls. yellow, in 2's or 3's on axillary peduncles: pods small, cylindrical; seed red, cream, black or mottled, small, average weight about .07 gram, oblong to nearly round, frequently with square end walls, ratio length to thickness (hilum to back) from 1:1 to 1.5:1; hilum $\frac{1}{2}$ in. (2 mm.) long or longer: primary lvs. ovate, their bases truncate or only slightly auriculate, their petioles $\frac{2}{5}$ in. (10 mm.) long or longer. Asia.—Cult. in N. China and

2895. Leaf of *Phaseolus vulgaris*.

2896. Cranberry Pole bean — *Phaseolus vulgaris*. ($\times \frac{1}{2}$)

Japan, where it is eaten boiled with soups or mixed with rice.

BB. Lfts. entire.

c. One wing rolled completely over keel: bases of primary lvs. cordate, their petioles $\frac{2}{5}$ in. long or longer.

6. *calcaratus*, Roxbg. RICE BEAN. Annual, erect, 1-2 ft. high, in habit much resembling the preceding species: lfts. broadly ovate: fls. yellow, in 2's or 3's in short axillary peduncles: seed varying in color from reddish brown to pale opaque, small, average weight about .05 gram, strongly elongated, ratio length to thickness (hilum to back) 1.75:1 to 2:1, hilum $\frac{1}{2}$ in. (2 mm.) long or longer: primary lvs. narrowly lanceolate. Asia.—Cult. sparingly in China and India, where it is used boiled in soups and with rice.

cc One wing pressed against but not rolled completely over the keel: bases of primary lvs. rounded or tapering, their petioles less than $\frac{2}{5}$ in. (7 mm.) long.

7. *aureus*, Roxbg. MUNG BEAN. Erect or slightly twining (some varieties strongly twining on rich ground), 1-3 ft. high, with furrowed sts. clothed with long brown hairs: lfts. broadly ovate or nearly rhomboid, orbicular, usually entire, thin, short-acute; stipules large, ovate: fls. rather small, yellowish, in clusters of 5-6 on the end of stout hairy peduncles; keel spurred: pod 3 in. or less long, nearly cylindrical, somewhat curved, bearing 10-15 beans; seeds green or golden, small, nearly round; average weight about .05 gram; hilum less than $\frac{1}{2}$ in. (2 mm.) long. Asia.—Cult. in China, where it is used for bean sprouts, vermicelli and gelatine, and extensively in India, also in Persia, Philippines, Japan. The slender pod is hairy at first, but the hairs are deciduous. *P. Mungo*, Linn. (THE URD), a related species, is distinguished by more procumbent habit, long-hairy pods, and oblong blackish seeds.

AA. Fls. not yellow.

B. Petioles of primary lvs. less than $\frac{3}{5}$ in. (7 mm.) long.

8. *acutifolius*, Gray, var. *latifolius*, G. F. Freeman. TEPARY. Fig. 2891. Annual, erect on poor or

2897. Long-podded forms of *Phaseolus vulgaris*.

dry land, under more favorable growth-conditions sts. recumbent, spreading or twining, $1\frac{1}{2}$ –9 ft. long, glabrous to puberulent: lvs. smooth above with slightly prominent veins beneath, glabrous throughout or slightly puberulent below; lfts. entire, ovate to broadly lanceolate, $\frac{3}{8}$ –2 in. wide (average width $1\frac{1}{2}$ in.), acuminate, stipellate; stipules lanceolate, $\frac{1}{2}$ in. long, striate, appressed; petioles slender, 1–4 in. long; peduncles shorter than the lvs., 2–5-fld.; bracts small, deciduous: fls. medium-sized, pedicellate, white or pale violet, few at the end of an axillary peduncle which is usually shorter than the lvs.; calyx short, broadly campanulate, 4-toothed (the upper 2 lobes united into 1), teeth acuminate; banner broad, emarginate, in fl. more than half reflexed, at the base biauriculate, $\frac{1}{2}$ – $\frac{3}{4}$ in. long; pod flattened and coriaceous when young, when mature papery, 2–7-seeded, 2–3½ in. long, $\frac{1}{8}$ – $\frac{3}{8}$ in. broad, straight or slightly curved, with prominent beak; seeds white, yellow, brown, or bluish black, either self-colored or variously flecked, round-oval to nearly round as is the navy, to strongly flattened like a diminutive lima; average weight .10–.20 gram. S.W. U. S. and Mex.—Cult. by the Indians and Mexicans of the southwestern desert region. Recently intro. by the Arizona Agric. Exp. Sta. as a very promising drought-resistant dry shell bean for hot semi-arid regions. See *Bean*, *Tepary*, p. 462; also *Ariz. Agric. Exp. Sta. Bull.* No. 68 (1912).

BB. Petioles of primary lvs. $\frac{3}{5}$ in. (10 mm.) long or longer.

c. Cotyledons not raised above the ground in the seedling.

9. *multiflorus*, Willd. SCARLET RUNNER BEAN. DUTCH CASE-KNIFE BEAN (a white variety). Figs. 2892–2894. Root thickened and tuberous, sometimes perennial in the S., but perishing in the N.: plant tall,

2898. Leaves of *Phaseolus lunatus*. Two upper ones, Willow Leaf, a very narrow-leaved form of the Sieva type; middle one, Potato Lima; lowest one, Large White Lima, the two latter being var. *macrocarpus*.

twining and slender, minutely pubescent: lvs. large; lfts. thin, terminal lfts. often 3 in. or more wide, rhombic-ovate and acute, scabrous-pubescent: fls. rather large and showy, on long naked racemes, in the Scarlet Runner type red, in the Dutch Case-Knife white, the keel not distinctly projecting: pods long (3–6 in.), with curved slender tip; seeds large ($\frac{3}{8}$ in. long or longer), much flattened or nearly cylindrical, less than twice as long as broad, not usually reniform, no conspicuous lines radiating from the hilum, color red or mahogany, and black in the Scarlet Runner, white in many other forms: primary lvs. ovate or cordate, the base deeply auriculate, petioles 1 in. or more long. S. Amer. or Mex., but now widely spread.—The Scarlet Runner form is popular as an ornamental vine for arbors and to cover windows, sometimes being known as Flowering Bean or Painted Lady. The Dutch Case-Knife is a vegetable-garden plant, grown for its beans. Various forms of the plant are grown for food by the Mexicans and these sometimes appear in our western country. Here belong the Aztec or prehistoric beans, now grown sparingly in N. Ariz., which are said to have originated from seed found in caches among the prehistoric cliff-dwellings. Melde's Perennial and Irvine's Hybrid beans are apparently white-fl. forms. The color of fl. and seed seems always to be associated in this species. A dwarf or bush form, probably of *P. multiflorus*, was intro. a few years ago as Bartelde's Dwarf Lima (see Bull. No. 87, Cornell Exp. Sta.). It is not unlikely that more than one species is passing as *P. multiflorus*, some of the Mexican forms being imperfectly understood.

cc. Cotyledons raised above the ground in the seedling stage.

d. Fl.-bracts large, conspicuous, oval.

10. *vulgaris*, Linn. COMMON BEAN. KIDNEY BEAN of the English. HARICOT of the French. Figs. 2895–2897. Erect or twining (on poor or dry soil many varieties are erect which are twining in more moist or fertile land; some varieties, however, retain the bush form under the most favorable conditions): mature plants more or less pubescent: lfts. rhombic-ovate or ovate, acuminate; peduncles shorter than the petioles, few-fld. at or near the apex: fls. small, white, yellowish or blue-purple; pod slender, somewhat curved, provided with a straight or curved tip, fleshy when young and either green or light yellowish wax-color; length of mature seed less than $\frac{1}{2}$ in., average weight more than .20 gram, no conspicuous lines radiating from the hilum: primary lvs. entire, cordate, deeply auriculate, dull green, slightly rough from fine scattered hispid pubescence, their petioles distinctly pubescent.—Both seed and plant characters very variable. There are probably about 200 distinct types, which include between 400 and 500 named commercial varieties. Here are included all of both bush and running forms of which the pods are used as green snap beans as well as the dry shell-bean type like the Navy, Boston Pea, and California Tree bean. The seven species of common beans (*P. vulgaris*, Savi, *P. compressus*, Mart., *P. gonospermus*, Savi, *P. carinatus*, Mart., *P. oblongus*, Savi, *P. ellipticus*, Mart., *P. sphaericus*, Mart.) which were separated by George von Martens (Die Gartenbohnen, 1860) according to the shape and size of

2899. Pods of Sieva, Large Lima, Potato Lima. The last two are forms of *P. lunatus* var. *macrocarpus*. ($\times \frac{1}{2}$)

the seeds, are now recognized by botanists as different varieties of *P. vulgaris*, Linn. For cult., see *Bean*. For descriptions of commercial varieties see H. C. Irish, "Garden Beans Cultivated as Esculents," Missouri Bot. Garden, 12th Ann. Rept. (1901), pp. 81-165; W. W. Tracy, Jr., "American Varieties of Garden Beans," U. S. Bur. Plant Ind., Bull. No. 109 (1907), pp. 5-173; C. D. Jarvis, "American Varieties of Beans," Cornell Bull. No. 260 (1908), pp. 149-245.

2900. Henderson Dwarf Lima, a form of *Phaseolus lunatus*. ($\times \frac{1}{2}$)

DD. Fl.-bracts small, inconspicuous, lanceolate.

11. *lunatus*, Linn. SIEVA OR CIVET BEAN. Figs. 2898-2901. Small and slender, usually not climbing very high: lfts. thin, short and broad, ovate pointed (except in special forms as the Willow-leaf): fls. of medium size, wings and keel white or whitish, banner greenish, containing chlorophyll, of different texture from the wings and keel, in axillary racemes: pods small and papery, 2-3 in. long, much curved on the back and provided with a long tip, splitting open when ripe and the valves twisting; beans small and flat,

white, brown or mottled, conspicuous lines radiating from the hilum, more than $\frac{1}{2}$ in. long; primary lvs. not lobed, in form ovate or cordate, bases deeply auriculate, upper surfaces smooth and somewhat shiny, their petioles almost perfectly glabrous. Trop. Amer.—Widely cult. in warm countries, and prized for its earliness and prolificacy. It gives rise to dwarf or bush forms, as the Dwarf Carolina, Henderson Bush Lima. Common in American gardens Var. *macrocarpus*, Benth. (*P. inamœnus*, Linn. *P. lmeensis*, P. *saccharatus*, P. *fœcundus*, P. *latissiliquus*, Macfadyen. *P. puberulus*, HBK. *P. Xuarézi*, Zucc.). LIMA BEAN. Figs. 2898, 2899. Distinguished from the Sievas by tall, robust growth and late ripening: lfts. large and thick, ovate-lanceolate; pods fewer to the raceme, straight or nearly so, without a prominent tip, not readily splitting at maturity; beans very large, white, red, black, or speckled. S. Amer.—Widely grown in the tropics, and one of the richest of beans. Unreliable in the northern states because of the short, cool seasons. There are 2 forms cult. in the U. S.: Flat or Large-seeded limas, with seeds very flat and veiny and more or less lunate in shape, and very broad flat pods, with a distinct but not prominent point, and broad ovate lfts.; Potato limas, with smaller tumid seeds, shorter and thicker pods, with a very short point, and long-ovate, tapering lfts., with angular base. In both these groups there are dwarf or bush forms.—Burpee Dwarf Lima in the former, and Kumerle Dwarf Lima in the latter. The lima bean is perennial in the tropics. See *Bean*, *Lima*.

GEO. F. FREEMAN.

PHAYLÓPSIS (Greek, *worthless*, and *appearance*). Also spelled *Phailopsis*. Syn., *Micranthus*, Wendl., not Eckl. *Acanthaceæ*. Small shrubs, probably not now in cult.: lvs. often oblique, those in one opposite pair unequal, elliptic, entire, or crenate: infl. in cylindric or

ovoid spikes, each broad floral lf. inclosing a contracted cyme of usually 3 fls.; calyx 5-lobed nearly to the base; corolla small, 5-lobed; stamens 4: caps. ellipsoid, compressed, usually 4-seeded. About 15 species, Afr., Mascarene Isls. and India. *P. parviflora*, Willd. Pubescent: st. 1-2 ft. high, branched: lvs. acuminate at both ends, nearly entire: calyx hairy, 2 antecus segms. linear-ligulate; corolla white or purplish, tube funnel-shaped at the top; ovary glabrous. Trop. and S. Afr., Mascarene Isls., and India. B.M. 2433 (as *P. longifolia*).

PHEGÓPTERIS (Greek, *beech-fern*). *Polypodiaceæ*. BEECH, OAK or SUN FERN. A group of ferns like *Dryopteris* in habit and latterly usually included in that genus, but with no indusia, the sori being entirely naked. There are numerous Trop. American and Sandwich Island species worthy of cult. in warmhouses. There are 3 native hardy species sometimes offered in the trade, the first, second, and fourth in the following list. For cult., see *Ferns*.

A. Lvs. small or medium-sized, at most tripinnatifid. (Native hardy species.)

B. The lvs. bipinnatifid, broadly triangular.

hexagonóptera, Fée (*Polypodium hexagonópteron*, Michx.). Lvs. 9-15 in. long, usually broader than long, pale green; lower pair of pinnæ deflexed and set forward; sori marginal. E. U. S.—Suitable for shaded banks with good soil and fair moisture.

polypodioides, Fée. Lvs. 5-9 in. long, longer than broad, dark green, slightly hairy beneath; sori nearer the margin than the midrib. Eu. and N. E. N. Amer. G.M. 58:297 (as *Polypodium phegopteris*).—Like preceding in cultural requirements.

BB. The lvs. tripinnatifid, lanceolate.

alpéstris, Mett. Lvs. 1-2 ft. long, 6-8 in. wide, with numerous finely cut lanceolate pinnæ, the lobes toothed; thinly herbaceous. Eu. and N. W. Amer.—Habit of *Athyrium* (or *Asplenium*) *Filix-femina* and is probably an *Athyrium*.

BBB. The lvs. ternately tripinnatifid.

Dryópterus, Fée. OAK FERN. Lvs. triangular, 3-9 in. each way, the lowest pinnæ nearly equal to the terminal, giving the lf. a ternate appearance Eu. and N. Amer.—Grows in damp places in nearly pure leaf-mold.

AA. Lvs. several feet long, decomposed.

Keraudreniana, Mann. Lvs. several feet long, decomposed, with light brownish polished stalks and straw-colored rachides; texture herbaceous; sori near the margins of the segms. Sandwich Isls.—A greenhouse species. This species has also been advertised under the name of *Polypodium*.

L. M. UNDERWOOD.

R. C. BENEDICT.†

PHELLODÉNDRON (Greek, for *cork*, and *tree*, alluding to the corky bark). *Rutaceæ*. CORK TREE. Ornamental trees, grown for their handsome foliage.

Deciduous: winter buds naked, inclosed by the base of the petiole: lvs. opposite, petioled, without stipules, odd-pinnate, with opposite crenulate lfts.: fls. diceious, in terminal panicles, or the staminate fls. nearly corymbose; sepals and petals 5-8, ovate-lanceolate; stamens 5-6, longer than petals; ovary 5-celled, with a short thick style: fr. a black drupe with 5 small 1-seeded stones.—Five or 6 closely related species in E. Asia.

2901. Sieva bean.—*Phaseolus lunatus*. ($\times \frac{1}{2}$)

The cork trees are usually medium-sized trees with rather stout spreading branches, forming a round broad head, with large leaves of aromatic odor when bruised and turning yellow in autumn, and with inconspicuous greenish flowers followed by black berry-like fruits remaining on the tree a long time after the leaves have fallen. *P. amurense* and *P. sachalinense* are hardy North, while the other species seem somewhat tenderer but have proved hardy as far north as Massachusetts. They are of rapid growth when young and seem to grow in almost any kind of soil. The first-named species has been recommended as a street tree for western cities, as it resists drought and heat in summer and seems not to be attacked by insects. Propagation is by seeds, which are produced freely when both sexes are planted, and by root cuttings dug up in fall and stored during the winter in moist sand or sphagnum; cuttings taken from the tree in July with a "heel" of older wood will root in gentle heat.

A. *Lvs. glabrous beneath or with a few scattered hairs on the midrib, glaucescent or glaucous.*

amurense, Rupr. AMOOR CORK TREE. Tree, to 50 ft.: bark of the trunk light gray, corky, deeply fissured: 1-year-old branchlets orange-yellow or yellowish gray, almost glabrous: lfts. 5-13, ovate to ovate-lanceolate, narrowed or rounded at the base, long-acuminate, minutely crenulate, and ciliate, dark green and lustrous above, glaucescent and glabrous beneath or with a few scattered hairs near the base of the midrib, 2-4 in. long: infl. puberulous: fr. globose, black, about $\frac{1}{8}$ - $\frac{1}{2}$ in. across, with a strong turpentine-like odor when bruised, in broad panicles, 2-3 $\frac{1}{2}$ in. across. June. N. China, Amurland, Japan. S.T.S. 1:93. S.I.F. 2:33. Var. **álbo-variegátum**, Scherwin. Lvs. variegated with large white blotches.—A hybrid between this species and *P. japonicum* has been observed in the Botanic Garden at Lund, Sweden.

sachalinense, Sarg. Tree, to 50 ft.: bark of the trunk dark brown, slightly fissured and broken into thin plates, not corky: 1-year-old branchlets reddish brown: lfts. 7-11, ovate to ovate-oblong, acuminate, cuneate or rounded at the base, minutely crenulate and glabrous or sparingly ciliate on the margin, dull green above, glaucescent beneath and glabrous or nearly so, 3-5 in. long: infl. nearly glabrous: fr. black, $\frac{1}{3}$ in. across or slightly more, in broad panicles 2-3 $\frac{1}{2}$ in. across. June. Saghalin, Korea, N. Japan, W. China. S.T.S. 1:94.—This is the most satisfactory and hardiest species in cult.; it forms a tall trunk with a broad crown.

AA. *Lvs. pubescent beneath, at least on the veins, and pale green or grayish green.*

B. *Infl. as broad or nearly as broad as high: ovary glabrous.*

Lavalléi, Dode. Tree, to 30 or occasionally to 50 ft.: bark corky: 1-year-old branchlets purplish brown: lf-rachis puberulous or pubescent; lfts. 5-13, elliptic-ovate to oblong-lanceolate, acuminate, cuneate at the base, minutely crenulate and ciliate, dull yellowish green above, pubescent beneath while young, at maturity often only on the veins, 2-4 in. long: infl. puberulous: fr. black, $\frac{1}{3}$ in. across, in rather loose broad panicles 2 $\frac{1}{2}$ -4 in. across. June. Cent. Japan. I.T. 5:171 (as *P. amurense*).—Often confused with *P. japonicum* and cult. under that name.

japónicum, Maxim. Tree, to 30 ft., with slightly fissured dark brown bark, not corky: 1-year-old branches reddish brown: lf-rachis densely villous or tomentose; lfts. 9-13, ovate to ovate-oblong, acuminate, truncate or subcordate and very unequal at the base, minutely crenulate and ciliate, dull green above, villous beneath all over, more densely on the veins, 3-4 in. long: infl. hoary-tomentose: fr. black, nearly $\frac{1}{2}$ in. thick, in broad panicles 2-3 $\frac{1}{2}$ in. across. June. Cent. Japan. S.T.S. 1:95.

BB. *Infl. distinctly higher than broad: ovary pubescent.*

chinense, Schneid. Tree, to 30 ft.: bark dark grayish brown, slightly fissured, not corky: 1-year-old branchlets purplish brown: lfts. 7-13, oblong-ovate to oblong-lanceolate, acuminate, rounded or broadly cuneate at the base, dark yellowish green above, villous beneath, 3 $\frac{1}{2}$ -5 $\frac{1}{2}$ in. long: infl. densely pubescent: fr. black, nearly $\frac{1}{2}$ in. across, in panicles about 1-2 $\frac{1}{2}$ in. broad and 2-3 in. long. Cent. China. Var. **glabriúsculum**, Schneid. (*P. sinense*, Dode). Lfts. pubescent only on the veins beneath. Cent. and W. China. ALFRED REHDER.

PHELYPÆA (after Louis and Hier. Phelipeaux). Also spelled *Phelipæa*. *Orobanchææ*. Herbs, puberulent or glabrous, from a thick short few-scaled base: scapes simple, elongated, remotely few-scaled or the elongated peduncles naked, scape-like, always 1-fl., bractless; calyx 5-parted, broad-campanulate, lobes acute, unequal; corolla-tube broadly ventricose, incurved, limb sub-2-labiate, with 5 broadly rounded not very unequal lobes, anterior lip at base gibbous or with 2 broad glandulose-pubescent spots; stamens included; ovary with 4 placentæ: fr. a perfect 2-valved acute, ovate caps.—About 5 species, chiefly in the Orient, but also in N. Afr. and Asia. *P. foliata*, Lamb. Parasitic leafless herb 1-1 $\frac{1}{2}$ ft. high: sts. simple, rather stout, glandular-puberulous, reddish: fl. solitary, terminal, ebracteate; calyx campanulate, unequally 5-lobed, usually somewhat 2-lipped, lobes oblong or ovate, deep red or chestnut-brown; corolla ringent, tube widely and obliquely campanulate, orange flushed with red outside, limb 2-lipped, reddish yellow outside, brilliant crimson within, the throat with 2 black hirsute spots: fr. a wide ovate caps. nearly $\frac{1}{2}$ in. long. Caucasus. It has been raised in botanic gardens in Eu.

F. TRACY HUBBARD.

PHENOLOGY (contraction of *phenomenology*; that is, the science of phenomena) is the study of the relationships between the climate of any place and the annual periods of plants and animals. Plants vegetate, bloom, and ripen fruit at more or less definite seasons, each after its kind; animals mate, bear young, migrate and hibernate each also after its kind; but these recurring events are related to the climate in which these things live: with these inter-relationships phenology has to do. The most complete means of comparing the climate of one year with that of another are the life-events of the animals and plants of the years. Thermometrical readings are the customary measures, but the thermometers record only temperature, whereas local climate is modified by conditions of humidity, cloudiness, the sequence of atmospheric changes, and many subtle agencies which cannot be measured by means of instruments. Living things are the agents that really measure climate. A record of the life-events of living things, therefore, even though imperfect, should contribute to the science of climatology; and incidentally it should contribute much to the science of biology. Records of plant-events are more comparable than those of animal-events, because plants are stationary and have no volition to adapt themselves to inclemencies by means of change of position, diet, or otherwise; therefore, plants emphatically express climatal influence. A record of the first blooming of a given apple tree, for example, during a series of years would give comparable measures of the lateness or earliness of the different seasons. Most so-called phenological observations in this country have been mere records of dates of blooming, leafing, migration of birds, peeping of frogs, and the like, without correlative data respecting the local climate. They are therefore of relatively little consequence to science. In this country the literature of phenology is meager. See Bailey, Essay 17, "Survival of the Unlike," and "Weather Review," Sept. 1896, U. S. Weather Bureau. L. H. B.

PHENOMENAL BERRY: See article on *Loganberry*, page 1900.

PHILADELPHUS (named for the ancient Egyptian king, Ptolemy Philadelphus, who reigned from 285 to 247 B.C.). *Saxifragaceæ*. SYRINGA. MOCK ORANGE. Popular ornamental deciduous or rarely half-evergreen shrubs.

Leaves opposite, entire to variously toothed, occasionally slightly revolute, and almost invariably ciliate: fls. often very fragrant, mostly white, a few creamy or with purple or rosy spots at or near the base of the petals, in racemes, or solitary or in cymose groups of 1-6; calyx-lobes, petals, and styles usually 4; stamens numerous: fr. a dehiscent commonly 2-parted 4-valved many-seeded caps.—About 30-35 species have been described. The genus is essentially Asiatic and American. *P. coronarius* is certainly a native of Armenia and the Caucasus, and several varieties of it

2902. *Philadelphus coronarius*.

extend the range to Japan, and it is wild in Eu., but whether or where it is native is uncertain, because it has undoubtedly sometimes escaped from cult. The genus has 3 roughly defined areas of distribution.—N. Asia and Japan, W. Amer. from Brit. Col. to Calif., S. Atlantic States, and Mex. It has no well-marked characters which may be used to separate the species, which therefore often resemble each other closely and are sometimes connected by intermediate forms. The latest treatment of the genus is in Schneider's *Illustriertes Handbuch der Laubholzkunde*, vol. 1, p. 362 (1905). On account of the great confusion of names in the genus, rather more synonymy than usual is given, but the selection is nevertheless of the names more likely to be met with or to cause confusion. The complete synonymy is far larger.

Syringa, the common name of *Philadelphus*, is identical with the generic name of the lilac. This arises from the use of *Syringa* by the old herbalists. Thus, in 1597, John Gerarde in his "Herball" gives *Syringa alba*, white pipe, *S. cærulea*, blue pipe, and *S. arabica*, Arabian pipe, the first being *Philadelphus coronarius*, the second *Syringa vulgaris* (lilac), and the third *Jasminum Sambac*. Tournefort, in 1700, selected *Syringa* for the first, but Linnaeus, whom we follow, chose to use it for the second. However, Tournefort's usage prevailed in English speech, while the Germans call *Philadelphus* either *Pfeifenstrauch* (=pipe-shrub, like the herbalists' "pipe," above) or *Jasmin*, perpetuating

the third element in the original heterogeneous *syringa*. The French also use *syringa* as the common name of *Philadelphus*, but in the form *seringat*.

Philadelphus generally blossoms in June; in fact, it is remarkable for the uniformity of the blossoming period, both in cultivation and in its native haunts, throughout the world. Most of the members of the genus are hardy North, except *P. Coulteri*, *P. mexicanus*, and the other Mexican species. They are well adapted to shrubberies and mostly do not grow very high, the tallest being *P. pubescens*, attaining a height of about 20 feet; others, as *P. coronarius*, *P. Zeyheri*, and *P. inodorus*, grow nearly as high, while *P. microphyllus* hardly exceeds 3 feet. If pruning is needed it should be done after flowering, since the flowers appear on the wood formed the previous year. Usually propagation is by hardwood cuttings, or by suckers and greenwood cuttings under glass; also by layers and by seeds, but when several species are growing together they are likely to hybridize.

INDEX.

For a few vernacular names, sometimes popularly written without a preceding specific name, see *P. Lemoinei*, of which they are really varieties.

A. Fls. in simple or rarely compound racemes (Nos. 1-20).

B. Calyx glabrous without, or with some scattered hairs (except in *P. sericanthus* and *P. incanus*).

C. Pistils little or not at all exceeding the stamens.

D. Styles separating less than half way down (except often in varieties of *P. Lemoinei*) (Nos. 1-12).

E. Lvs. some, generally most, of the mature ones more than $1\frac{1}{4}$ in. long.

F. The lvs. of young succulent shoots and suckers not approaching a circular outline, usually moderately toothed, if at all.

G. The calyx essentially glabrous without.

1. *nepalensis*, Koehne. Upright shrub to about 5 ft.: lvs. at maturity about $1\frac{1}{2}$ - $1\frac{3}{4}$ in. long, ovate-lanceolate, acuminate, even and distantly mucronate-denticulate, with white or yellowish tufts of hairs in the axils of lateral veins, especially on lvs. of young succulent shoots and suckers: fls. practically scentless; cup of the calyx and caps. plainly acute to long-pointed at base. June. N.E. Himalayas.

2. *Voie Lactée*. Hybrid between *P. nepalensis* and *P. microphyllus*. Similar to the preceding and superior to it, most readily distinguished by the lvs. of the young succulent shoots and suckers, which are more coarsely toothed, and not so long-pointed: caps. not seen, but probably more rounded at base. June. G.M. 55:554. G.W. 17, p. 103.

3. *pekinensis*, Rupr. (*P. coronarius* var. *pekinensis*, Maxim.). Erect shrub, to 5 ft., closely resembling *P. nepalensis*, but without the characteristic tufts of hairs on lower lf.-surfaces, and usually with purplish petioles. May, June. Mongolia, N. China.

4. *Zèyheri* (*P. Kochianus*, Koehne. *P. coronarius* *Zèyheri*, Schrad.). Hybrid of uncertain origin, probably between *P. coronarius* and *P. inodorus*. Lower than *P. coronarius*: lvs. variable, ovate to ovate-lanceolate, acute to acuminate, with hard-tipped teeth, glabrous or nearly so, or hairy along the veins beneath, those of young succulent shoots and suckers ovate-lanceolate to broadly ovate, sometimes with tufts of hairs on the youngest, as in *P. nepalensis*: fls. white, slightly fragrant or scentless.—A puzzling shrub, at times confusingly similar to *P. coronarius*. June.

5. *Lewisii*, Pursh (*P. columbianus*, Koehne. *P. Gordonianus*, Lindl. *P. californicus*, Benth. *P. cordifolius*, Lange). Upright shrub, to 8 ft., very variable: lvs. about 1–3 in. long, most not more than $2\frac{1}{2}$ in., about $\frac{1}{4}$ –2 (usually not more than $1\frac{1}{4}$) in. wide: racemes of varying length, generally but not always leafy; fls. white, borne in great profusion, in wild plants very fragrant, but, judging by some printed statements, not always retaining the odor under cult. June, July. Brit. Col. to Calif. B.R. 25:32.—Excellent.

6. *coronarius*, Linn. (*P. pallidus*, Hayek. *P. coronarius nivalis*, Hort.). Figs. 2902, 2903. Shrub, to 10 ft.: lvs. ovate-lanceolate (rarely ovate), generally acuminate, usually rather evenly mucronate-denticulate (exceptionally almost entire), rarely slightly serrate, thickish at maturity, about $1\frac{1}{2}$ –4 in. long, $\frac{1}{2}$ – $2\frac{3}{4}$ in. broad, slightly hairy beneath: fls. in rather dense racemes, white or more often with a slight creamy tone, very fragrant. May, June. Caucasus, Armenia, and probably S. E. Eu. B.B. 2:186. F.E. 39:75 (habit). J.H. III. 70:471.—This is the common syringa, or mock orange, with less attractive foliage than some, but the delicious fragrance unsurpassed. The following horticultural and 2 wild varieties are cult. Var. *flöre-plèno*, Hort. (*P. coronarius dianthiflorus*, *rosæflorus*, and probably *primulæflorus* and *multiflorus plenus*, and other names), with more or less double fls. Var. *foliis argenteo-marginatis*, Hort., lvs. white-margined. Var. *foliis aureis*, Hort., lvs. golden yellow. Var. *speciosissimus*, Hort. (*P. speciosissimus*, *P. Zèyheri speciosissimus*). Generally lower shrub than the species, with rather uniform and smaller lvs., broadly ovate to rotund. Var. *grandiflorus*, Hort. (*P.*

especially in wild specimens, with conspicuous hard-tipped teeth or serrations. Yunnan Province, China, Japan, and Tsu Shima. Var. *tomentosus*, Hook. f. & Thoms. (*P. tomentosus*, Wall. *P. nepalensis*, Lodd.). Shrub, to about 6 ft.: lvs. very hairy beneath. Himalayas and Tibet. Rather unattractive and of uncertain hardness.

GG. *The calyx tomentose.*

7. *sericanthus*, Koehne. Lvs. lanceolate, distantly blunt-toothed or entire, mature ones about $1\frac{1}{2}$ –4 in. long, $\frac{5}{8}$ –2 in. wide, glabrous beneath, or with few scattered hairs: fls. about $\frac{5}{8}$ in. across. June. Hupeh Province, China.—Larger-lvd. specimens have been distinguished as var. *Rehderianus*, Koehne.

8. *incanus*, Koehne. Lvs. ovate, more or less abruptly acuminate, dentate, with 5 principal veins, mature ones $1\frac{1}{2}$ – $4\frac{1}{4}$ in. long, $\frac{5}{8}$ in. across. June. Hupeh and Szechuan provinces. China.

FF. *The lvs. of young succulent shoots and suckers very large, ovate-lanceolate to orbicular, very coarsely toothed.*

9. *floribundus* (*P. verrucosus floribundus*, *P. grandiflorus floribundus*, Hort.). Hybrid of uncertain origin, probably with *P. coronarius* as one parent. Shrub resembling *P. coronarius*: lvs. generally hairier than in *P. coronarius*, and with characteristically very large, ovate-lanceolate to more often orbicular, generally coarsely toothed lvs. on young succulent shoots and suckers: fls. in racemes of about 5, about 2 in. across, slightly fragrant.

EE. *Lvs. rarely over $1\frac{1}{2}$ in. long (usually from about $\frac{1}{2}$ – $1\frac{1}{4}$ in.).*

10. *Lemôinei*. Hybrid of *P. coronarius* and *P. microphyllus*. Shrub with spreading branches, freely flowering: twigs and little branchlets with short hairs: ordinary mature lvs. ovate to ovate-lanceolate, rather uniform, rather small, glabrous or nearly so, acute to acuminate, with a few minute teeth, those of the young succulent shoots and suckers entire or remotely few-toothed, somewhat larger: fls. 2–9, in dense racemes, having a delicate but charming perfume. G.F. 2:617. G.L. 28:225.—The following horticultural varieties are of interest: Var. *erectus*. Flowering branches irregularly ascending, forming a more compact bush and less desirable. M.D.G. 1902:333. *Avalanche*. Graceful shrub, taller than other varieties, branches sometimes as long as 6 ft.: easily distinguished from the other varieties by its lanceolate lvs. G.C. III. 21:89. M.D.G. 1896:293; 1907:379. *Bouquet Blanc*. Lower lf.-surfaces and twigs with scattered hairs, distinctly visible: fls. in bouquet-like masses, not very fragrant. G.M. 55:487. G.W. 17, p. 101. *Candelabre*. Very low shrub, approaching *P. microphyllus* in size, hairy as in the preceding, but with a more open candelabra-like infl. M.D.G. 1896:294. *Mont Blanc*. Normally, probably, the most profusely flowering variety, but very variable in this respect. Hairs scarcely visible, a character at once distinguishing it from all the preceding. Exceedingly fragrant. *Manteau d'Hermine*. Twigs nearly or quite glabrous. *Pavillon Blanc*. Profusely flowering shrub: branches rounded or squarish in habit, twigs hairy: lvs. closely covered with silky hairs beneath. One of the most beautiful, and the sweetest scented of all the varieties, the perfume resembling that of *P. microphyllus*. *Gerbe de Neige*. Calyx hairy. *Boule d'Argent*. Fls. double, stamens mostly sterile, about $1\frac{1}{4}$ in. across, not very sweet-scented; calyx glabrous. Oldest and least desirable of double-flid. sorts. G.C. III. 18:18; 23:331. *Virginal*. Large double fragrant fls., $2\frac{1}{2}$ in. across, or wider. G.M. 54:459. R.H. 1910, pp. 408, 409. *Mer de Glace*. Double fls., similar to preceding. G.W. 17, p. 102. Var. *fimbriatus* is a distinct variety with large fls., petals twisted and deeply serrate. For other varieties of this hybrid consult list, p. 2582.

2903. *Philadelphus coronarius*.—Mock orange. ($\times \frac{1}{2}$)

grandiflorus, Hort.), with larger fls. than in the species, mostly 2 in. or more diam. Not to be confused with *P. inodorus* var. *grandiflorus*, Gray, below. Var. *salicifolius*, Hort. (*P. salicifolius* Hort., in part). Lvs. typically narrowly lanceolate, more or less willow-like, but sometimes, probably by reversion, broadly ovate, more coarsely toothed. Var. *nanus*, Schrad. (*P. nanus*, Hort. *P. salicifolius*, Hort., in part), dense bushy plants, usually not over $1\frac{1}{2}$ ft. high; long cult. and known to flower rarely. Var. *acuminatus*, A. H. Moore (*P. acuminatus*, Lange, *P. satsumi*, *P. satsumanus*, *P. yokohama* or *yokohamæ* of cult.). Lvs. more acuminate than in the species, the tips often bent to one side,

11. *phantasia* (*P. Lemoinei Fantaisie*). Hybrid between *P. Coulteri* and an unknown variety of *P. Lemoinei*. Fls. fragrant, white, tinted with pale rose at the center of the fl.; petals fringed at the edge. June. Var. *purpureo-maculatus*, Hort. Derivative of *P. phantasia*. Lvs. essentially as in *P. Lemoinei*, but proportionately somewhat broader, with numerous, short, stiff hairs beneath: fls. large, about $1\frac{3}{8}$ –2 in. across, exquisitely fragrant, with a purple spot at base of each petal; calyx with a few short, silky hairs. B.M. 8193.

12. *Étoile Rose*. Hybrid between *P. phantasia* and *P. purpureo-maculatus*. Lvs. small: fls. delicately fragrant, in rounded panicle-like racemes; petals elongate, rose-purple at base, the color diminishing toward the center of the fl. June.

DD. *Styles separated almost or entirely to the base, especially after flowering.*

13. *Conquete*. Hybrid of unknown origin. Lvs. lanceolate to narrowly ovate-lanceolate, glabrous, about 2–3 in. long, $\frac{5}{8}$ – $1\frac{1}{8}$ in. wide, entire, or with a few small teeth, on young succulent shoots and suckers larger, long-acuminate, coarsely toothed: fls. in a more or less compact but not head-like cluster, very large, to $2\frac{3}{4}$ in. across, sweet-scented; the slender thread-like styles cleft almost to the base, especially after flowering, stigmas generally short and small; calyx glabrous without. May, June. G.W. 17, p. 102.

14. *Nuée Blanche*. Hybrid between *P. microphyllus* and *P. nepalensis*. Lvs. ovate to ovate-lanceolate, glabrous, about $1\frac{1}{2}$ – $1\frac{3}{4}$ in. long, $\frac{5}{8}$ – $1\frac{1}{8}$ in. wide, entire or nearly so, on young succulent shoots and suckers ovate, acuminate, conspicuously toothed: fls. not over $1\frac{1}{2}$ in. across, sweet-scented; styles moderately slender, gradually broadening into the stigma; calyx glabrous without. May, June.

15. *Rosace*. Hybrid of unknown origin. Lvs. lanceolate, glabrous, about $1\frac{1}{2}$ – $3\frac{1}{4}$ in. long, $\frac{3}{8}$ to about 1 in. wide, entire, on young succulent shoots and suckers toothed: fls. very large, $1\frac{3}{4}$ – $2\frac{3}{4}$ in. across, sweet-scented; calyx glabrous without. May, June.

16. *Perle Blanche*. Shrub, to about $4\frac{3}{4}$ ft.: lvs. ovate, medium-sized, toothed, with small stiff scattered hairs beneath: fls. partly double, in head-like clusters, sweet-scented; calyx rather hairy without. May, June.

CC. *Pistils far exceeding the stamens.*

17. *Falconeri*, Sarg. Fig. 2904. Shrub, to 8 ft., with slender, arching branches: lvs. ovate-lanceolate, $1\frac{1}{2}$ –3 in. long, $\frac{1}{2}$ –1 in. wide, acuminate, entire or very minutely mucronate-denticulate: fls. in loose racemes of 1–6, fragrant, about $1\frac{1}{2}$ in. across; calyx-lobes very acuminate; petals rather narrow; pistils much longer than the stamens; styles separating as long slender filaments; stigmas scarcely broader than the styles. June. Origin unknown, probably Japanese. G.F. 8:497 (adapted in Fig. 2904). M.D.G. 1899:231. Gng. 8:340.

BB. *Calyx distinctly hairy or glabrate.*

18. *pubescens*, Loisel. (*P. latifolius*, Schrad. *P. grandiflorus*, P. W. Wats., under which name it is often met with, a name commonly also applied to varieties of *P. coronarius* and of *P. inodorus*, *P. nivalis*, and many other species or supposed species; it is also wrongly called *P. Gordonianus*). Shrub, to 20 ft.: bark of old branches grayish, either cracking when old and not peeling, or peeling in little flakes, so that shreds do not remain, of younger branches generally yellowish or greenish yellow: lvs. ovate to broadly elliptic or ovate-lanceolate, $1\frac{1}{2}$ – $4\frac{1}{2}$ in. long, $\frac{3}{4}$ –3 in. wide (those of young succulent shoots and suckers may attain dimensions of $7\frac{1}{4}$ × $6\frac{3}{4}$ in.), acute to acuminate, almost entire to more or less markedly mucronate-denticulate: fls. in long leafy racemes of 5–10, usually distant, somewhat

fragrant. June, July. Tenn., Ala. (last, according to Rydberg). Souvenir de Billiard (also cult. under the names *P. Billiardii* and *P. insignis*) is a horticultural variety, with ovate lvs. on the average smaller than in the species, about $1\frac{1}{4}$ – $2\frac{3}{8}$ in. long, erroneously described as a native species. Var. *intectus*, A. H.

2904. *Philadelphus Falconeri*. (× $\frac{1}{3}$)

Moore (*P. intectus*, Beadle). A natural variety with an externally wholly glabrous calyx, and with lvs. glabrous or nearly so. Tenn.

19. *verrucosus*, Schrad. A plant of uncertain origin: if hybrid, the parentage cannot be surmised. Similar to preceding, but bark of old branches purplish red or chestnut-brown, often peeling in shreds, of the younger generally brownish or reddish. June, July. Var. *pendulifolius* is a garden variety with slightly drooping branchlets.

20. *Magdalæna*, Koehne. Rather lower, spreading shrub, to about $5\frac{1}{2}$ ft.: the calyx generally with fewer short stiff hairs: otherwise closely resembling the preceding, lvs. inclined to be smaller.

AA. *Fls. borne singly or in clusters of 1–6 at the tips of the branchlets, not in racemes, except occasionally in P. mexicanus.*

B. *Pedicels and, externally, the calyx glabrous or nearly so: lvs. glabrous or with few scattered hairs.*

21. *inodorus*, Linn. (*P. coronarius* var. *inodorus*, Martyn. *Deutzia corymbosa*, Hort.). Shrub, to about 1 ft., much resembling *P. coronarius* in general appearance: lvs. ovate to ovate-lanceolate, about 1–6 in. long, $\frac{1}{2}$ – $1\frac{1}{4}$ in. broad, entire or with very few, usually very small, distant teeth. May, June. N. C. and Tenn. to Ga. and Miss. B.M. 1478. Usually hardy N. Long in cult.; inferior to *P. coronarius*. Var. *grandiflorus*, Gray (*P. grandiflorus*, Willd. *P. latus*, Lindl., also of Lodd. *P. latus* var. *grandiflorus*, Loud.). Lvs. generally more elongate, more coarsely toothed, especially on young succulent shoots and suckers. N. C. to Ga. and Fla. (last according to Rydberg), naturalized at Bushkill, Pa.

22. *latus*, Schrad. (*P. grandiflorus* var. *latus*, Torr. & Gray. *P. speciosus*, Schrad. *P. pubescens*, Lodd.). Shrub, to scarcely more than $1\frac{1}{2}$ ft.: lvs. narrowly lanceolate, with rarely a few ovate-lanceolate, teeth small, evenly disposed, on young succulent shoots and suckers more or less ovate-lanceolate, more coarsely toothed, sometimes with tufts of hairs in axils of lateral veins: fls. white. April, May. Szechuan Province, China. B.R. 25:39.

BB. *Pedicels and calyx densely hairy to tomentose (sometimes glabrate); lvs. more or less densely hairy to tomentose beneath.*

c. *Fls. white or cream-colored.*

23. *hirsutus*, Nutt. (*P. hirsutus* var. *gracilis*, Schrad. *P. inodorus* var. *hirsutus*, Wood. *P. trinervius*, Schrad. *P. inodorus*, Schrad.). Upright or spreading shrub, to 8 ft.: lvs. lanceolate to ovate-lanceolate, 1–2¾ in. long, ¾–1½ in. wide, acuminate, regularly serrate (rarely denticulate), usually with more or less numerous short, rough hairs above, closely silvery-gray coated beneath, thin and papery when young. April–June. Rocky river banks, Tenn., N. C., Ga., Ala. Gn. 26, p. 375; 34, p. 138. B.R. 24:14. B.M. 5334.

24. *mexicanus*, Schlecht. (*P. guatemalensis*, and *P. sempervirens* applied to this in Calif. are apparently garden names). Evergreen shrub, to about 6½ ft.: lvs. ovate, 1¾ in. long, ¾–1½ in. wide, acute to short-acuminate, distantly blunt-toothed, glabrous or spar-

2905. *Philadelphus Coulteri*. (×%)

ingly hairy above, scabrous beneath with short stiff, closely appressed hairs, in general pointing toward the apex: fls. occasionally in short leafy racemes (a transition to the first great subdivision of the genus, see A in key on p. 2579), 2 in. across, cream-colored, fragrant. Mex. and, it is said, Guatemala. B.M. 7600. B.R. 28:37. R.H. 1852:381. G.C. II. 19:753; 34:218.

25. *microphyllus*, Gray. Erect, to 6 ft. (usually not so tall), or in its native habitat sometimes sprawling, with spreading slender or rigid branches: lvs. oblong-ovate, ¾–1 in. long, ¼–½ in. wide, acute or subacute (rarely obtuse), entire, scarcely if at all revolute more or less densely covered with silky hairs beneath, glabrous or with short hairs above: fls. ½–¾ in. across, white, exquisitely fragrant: caps. ¼–¾ in. long, ¼–½ in. wide, glabrous or slightly hairy. June, July. Utah and Colo. to Ariz., N. Mex., and Calif. G.C. III. 2:156; 11:86; 51:225. Gn. 40:288. P.G. 5:109.

cc. *Fls. with a purple spot at base.*

26. *Coulteri*, Wats. (*P. mexicanus* var. *Coulteri*, Burb.). Fig. 2905. Shrub, to about 10 ft.: lvs. ovate, 1½–2 in. long, ¾–¾ in. wide, obtusely to sharply pointed, on young succulent shoots and suckers, larger toothed, those of both young and old covered with rough hairs above and very white-tomentose beneath, the whole like a rough piece of felt: fls. white, very fragrant; petals with red spot at the base; calyx covered with silvery white silky hair; caps. unusually large, about ½ in. long. States of Nuevo Leon and Hidalgo, Mex. G.F. 1:233 (adapted in Fig. 2905). B.R. 14.—Very distinct, desirable for southern latitudes, and one of the most pleasing of the genus.

P. argenteus, Rydb. Low straggling shrub, with handsome silvery calyx, and lvs. silvery beneath. Fort Huachuca, Ariz. Rare plant for southern rockeries or borders. Because of rarity, only one plant, or preferably seeds, should be got, to prevent extermination.—*P. brachybotrys*, Koehne (*P. pectinatus* var. *brachybotrys*, Koehne). Of uncertain standing, allied to *P. coronarius*. The following variety is of greater merit. Var. *purpureascens*, Koehne. With purple calyx and pedicels. B.M. 8324 (as *P. Delavayi*).—*P. chinensis*=*P. coronarius* var. *acuminatus*.—*P. coronarius* var. *nikoensis*, A. H. Moore (*P. satumanus* var. *nikoensis*, Rehd.). Related to var. *acuminatus*, differing in greater pubescence,

especially on the veins of lower lf.-surfaces.—*P. coronarius* var. *sempervirens*. Uncertain, probably=*P. coronarius* flore-pleno.—*P. coronarius* var. *tenuifolius*, Maxim. A variety differing but slightly from the type, of no advantage to horticulture.—*P. Delavayi*, L. Henry. Chinese, with fragrant fls., and generally more or less fringed petals, often marked with purple on the back. R.H. 1903, p. 13. Var. *melanocalyx*, Hort., is a variety with dark purple calyx.—*P. Dresden*. Hybrid of *P. Lemoinei* erectus and *P. pubescens*. Desirable.—*P. floridus*, Beadle. Desirable shrub, erect, to 6½ ft.; with attractive large, white fls., and calyx appressed silky. Suitable for S.E., and perhaps hardy N., like other southern species of this genus.—*P. Goddardii*. Name said to stand for *P. hirsutus* and *P. latus* in gardens.—*P. grandiflorus* *albus*. Not possible to determine, because of confusion existing in regard to name *grandiflorus*.—*P. grandiflorus* *latus* flore-pleno. See note on preceding name.—*P. inodorus* *sanguineus*. Unknown. Name *P. inodorus* also variously applied.—*P. Lemoinei*. Of many varieties recently produced, but not yet intro. into American trade, the following seem worthy of mention. (See also derivatives of *P. phantasia*, originally treated as varieties of *P. Lemoinei*, under the former name.) *Albre*. Branches more graceful than in the variety *Virginal*: lvs. smaller: fls. full double as in that variety. *Bannière*. Branches arched with the weight of the fls., which are about 1½ in. across. *Dame Blanche*. Fls. creamy white, very fragrant; petals fringed. *Norma*. Profusely flowering: fls. large, white. *Ophelia*. Gracefully arching branches: fls. white, fragrant.—*P. magnificus*, Rehd. Garden hybrid of *P. inodorus* and *P. pubescens*.—*P. mazzonis*, Rehd. Garden hybrid of uncertain origin; resembling *P. coronarius* (perhaps hybrid of that with *P. pubescens*), but with the lvs. of young succulent shoots and suckers very large, hairy beneath. Not of horticultural merit.—*P. nepalensis* *variegatus*. Name of unknown application.—*P. phantasia*. The following varieties not yet in the American trade are of interest: *Oeil de Pourpre*. Fls. fragrant; petals with black-purple spot at base. *Romeo*. Profusely flowering: fls. creamy white, with a purple blotch. *Sirène*. Fls. large, fragrant, white, with a very slight suggestion of rose in the lower corners of the petals. *Surprise*. Fls. fragrant; petals spotted carmine-purple. *Sybil*. Shrub with long curved branches, of pretty habit; fls. white, slightly fringed; petals pale pink spotted toward base.—*P. purpureascens*, Rehd.=*P. brachybotrys* var. *purpureascens*.—*P. Schröderii*, Rupr. Closely related to *P. coronarius*. Upright: lvs. large and thin: fls. scentless, smaller; style appressed pubescent at base. Var. *Jackii*. Of uncertain hybrid parentage and doubtful merit.—*P. sempervirens*, Hort., offered in Calif., is *P. mexicanus*, described in No. 24; the name appears to have no botanical standing.—*P. serpyllifolius*, Gray. Closely related to *P. microphyllus*, than which it is more straggling, and less attractive, although perhaps good for rockeries. The only species with leathery revolute lvs.—*P. splendens*. Supposed garden hybrid, said to be worthy of cult.—*P. stenopetalus*, Carr. This is a species whose description in important particulars suggests *P. Falconeri*, for which it may prove to be an older name.—*P. tenuifolius*, Rupr.=*P. coronarius* var. *tenuifolius*, Maxim. Not of horticultural merit.—*P. umbellatus*, Koehne. Probably hybrid of *P. coronarius* and *P. inodorus*: fls. in broad 2–5-fl. panicles, compound of long-peduncled cymes. Parentage unknown.—*P. venustus*, Koehne. Closely related to *P. coronarius* var. *tomentosus*. Perhaps distinct.—*P. Wilsonii*, Koehne. New Chinese species of the group of *P. incanus*. Value unknown.

ALBERT HANFORD MOORE.

PHILAGÈRIA (a name composed from the parent genera). *Liliacæ*. A hybrid genus between *Philesia buxifolia* and *Lapageria rosea*. A smooth climbing shrub: sts. flexuous, rigid, cylindrical: lvs. alternate, petiolate, leathery, smooth, oblong-acute, 3-nerved: fls. pendulous; sepals glaucous, pale rose-purple; petals imbricate, scarcely open at the apex; anthers 6; ovary free, 1-celled.—One species, a greenhouse hybrid, *P. Veitchii*, Mast. G.C. 1872:358; III. 55:399. Apparently not in cult. at the present time. See *Lapageria*.

PHILÈSIA (Greek, *lovely*). *Liliacæ*. An interesting shrub of extra-tropical South America, little grown. See *Lapageria* and *Philageria*.

Species one, a woody plant bearing showy pendulous red *lapageria*-like fls. about 2 in. long. It is unlike the ordinary lily types with 6 similar perianth-segms., for it has distinct calyx and corolla parts of 3 sepals and 3 petals. It is closely allied to *Lapageria*, but differs in habit, in the calycine character of the outer perianth and the monadelphous stamens. It is said to live outdoors in the most favored localities of England and Ireland.

Philesia is too slow-growing ever to become very popular. It is a short-jointed hard-wooded shrub, with rather leathery box-like leaves, and will grow to about 4 feet in height in time. The writer's experience with this plant was in a camellia house, in which a night temperature of 45° was maintained, the plants being firmly potted in a light peaty soil. It flowered but

sparingly in the latter part of the summer. The flowers were borne only singly in the axils of the leaves. Cuttings may be rooted when taken from ripened growth, but require careful management in a cool temperature, and are usually several months in rooting. If one tries to grow philesia in a too high temperature, the general result is a good crop of thrips and a case of general debility, much as with *Pernettya mucronata* under similar conditions. Philesia is probably not extraordinarily hard to manage, provided it is kept cool and in a dewy atmosphere, but it will positively rebel against forcing. (W. H. Taplin.)

buxifolia, Lam. (*P. magellanica*, Gmel.). Much branched, 3-4 ft.: lvs. alternate, linear-oblong, 1-1½ in. long, leathery, evergreen, feather-veined, glabrous, glaucous beneath; margins reflexed; petiole jointed at the junction of the blade: fls. solitary, bright rosy red; petals wavy; filaments united into a tube below the middle, then free; ovary 1-celled, with 3 short parietal placenta which bear several ovules: fr. a berry. S. Chile to Magellan. B.M. 4738. F. 1854:65. G.C. II. 18:105; III. 55, suppl. June 6. J.H. III. 42:299. G. 36:329. H.F. 4:72.

WILHELM MILLER.

PHILIBERTÉLLA: *Philibertia*.

PHILIBÉRTIA (after G. C. Philibert). Incl. *Sarcostemma* and *Philibertia*. *Asclepiadaceæ*. Climbing shrubs or half-shrubs, white-pubescent or glabrous, sometimes grown under glass or far S. for ornament: lvs. opposite: infl. umbelliform cymes, pedunculate in one axil or rarely sessile; fls. variable in size, often greenish white; calyx small, 5-parted, minutely 5-glandulose within, lobes acute; corolla very broadly campanulate or subrotate, divided slightly to the middle or deeply 5-cleft, with the lobes twisted and narrowly overlapping to the right; exterior crown membranaceous, ring-like, adnate to the base of the corolla, free from the stamen-tube or more or less connate with the median wings of the opposite anther, interior 5 crown-scales adnate with the base of staminal tube, with a variable lamina; stamens affixed to the base of the corolla, the filaments forming a short tube: fr. smooth, acuminate, somewhat thickened follicles.—About 30 species, Trop. and Subtrop. Amer. *P. clausa*, Schumann (*Philibertia clausa*, Vail). Sts. glabrous or minutely pubescent at the nodes: lvs. ovate-oblong or lanceolate-oblong, apex acute or acuminate, base rounded or subcordate, peduncles twice as long as the lvs., or more: fls. many; calyx-lobes oblong-lanceolate, acute, pubescent; corolla white, lobes oblong, fimbriate-ciliate. Fla.—A twining perennial with glossy evergreen lvs. and very sweet-scented fls., which has been offered in the trade-lists. *P. gracilis*, D. Don (*P. grandiflora*, Hook.). Twining shrub: lvs. opposite, cordate at base: the umbels borne between the petioles; calyx 5 deep acuminate segms.; corolla rotate-campanulate, more than 1 in. diam., with 5 triangular segms. and a small tooth between them, cream-colored dotted and streaked with purple inside. S. Amer. B.M. 3618. H.U. 2, p. 261. Cult. to some extent in Eu.

F. TRACY HUBBARD.

PHILLÝREA (its ancient Greek name). *Oleaceæ*. Ornamental woody plants, grown for their handsome evergreen foliage.

Evergreen shrubs or small trees: lvs. opposite, short-petioled, entire or serrate, quite glabrous: fls. small, in axillary short racemes, dioecious; calyx 4-toothed; corolla 4-lobed, with short tube; stamens 2, with very short filaments; style shorter than tube; ovary 2-celled: fr. a 1-seeded black drupe.—Five species in the Medit. region. The name is sometimes misspelled *Filaria*.

The phillyreas have small, or in one species rather large leaves, and small white flowers, followed by small

berry-like purplish black fruits. The species are hardy only South, but *P. decora*, the handsomest of all the species, is probably hardy in sheltered positions as far north as Massachusetts. They may be used in the southern states and California for evergreen shrubberies in drier and more exposed localities. They grow in almost any soil and prefer sunny positions; but *P. decora* seems to grow better if partly shaded. Propagation is by seeds sown after maturity and by cuttings of half-ripened wood under glass in summer or by layers; they are also sometimes grafted on *Ligustrum ovalifolium*.

A. Lvs. ¾-2 in. long: fr. small.

B. Shape of lvs. roundish oval to oblong-lanceolate, usually serrate.

latifolia, Linn. Shrub or small tree, to 30 ft., with spreading, somewhat rigid branches: lvs. ovate or oval to ovate-oblong, rounded or slightly cordate at the base, usually serrate, dark green and shining above, pale beneath, ¾-1½ in. long: fr. globose, concave at the apex. May, June. S. Eu., N. Afr. H.W. 3, p. 123. R.F.G. 17:1075. There are several varieties. Var. *lævis*, Ait. Lvs. ovate, almost entire or slightly serrulate. Var. *rotundifolia*, Arb. Kew. Lvs. broadly ovate or roundish ovate. Var. *spinosa*, Ait. (*P. ilicifolia*, Willd.). Lvs. ovate or ovate-oblong, sharply serrate.

mèdia, Linn. (*P. latifolia* var. *mèdia*, Schneid.). Spreading shrub, to 20 ft.: young branchlets puberulous: lvs. oblong-ovate to ovate-lanceolate, entire or serrate, dark green and shining above, ¾-2 in. long: fr. ovoid, pointed. May, June. Medit. region. N.D. 2:27. G.O.H. 116. R.F.G. 17:1075.—This species seems to be somewhat harder than the preceding and the following; the most important of the many varieties are the following: Var. *buxifolia*, Ait., with oblong-ovate, obtusish lvs. Var. *oleæfolia*, Ait. (*P. oleæfolia*, Hort.). Lvs. oblong-lanceolate, almost entire: branches erect. Var. *péndula*, Ait. Branches spreading and somewhat pendulous: lvs. lanceolate.

BB. Shape of lvs. lanceolate to linear-lanceolate.

angustifolia, Linn. Spreading shrub, to 15 ft., with glabrous branchlets: lvs. oblong-lanceolate to linear-lanceolate, usually entire, dull green above, 1-2 in. long: fr. globose or ovoid-globose, pointed. May, June. Medit. region. G.O.H. 115. R.F.G. 17:1076. Var. *lanceolata*, Ait. Lvs. lanceolate, about 1 in. long. Var. *rosmarinifolia*, Ait., has linear-lanceolate lvs., sometimes over 2 in. long, and erect branches. The 3 preceding species are very closely related to each other and considered by some botanists to be varieties of only 1 species and designated as *P. variabilis*, Timbal & Loret, or *P. vulgaris*, Caruel.

AA. Lvs. 3-5 in. long: fr. ½ in. long.

decora, Boiss. & Bal. (*P. Vilmoriniana*, Boiss. & Bal. *P. laurifolia*, Hort. *P. Medwediewi*, Sred.). Shrub, to 10 ft., with spreading branches: lvs. oblong to oblong-lanceolate, acuminate, usually entire or remotely serrulate, dark green and shining above, yellowish green beneath: fr. oblong-ovoid, purplish black. June, July. W. Asia. B.M. 6800. G.C. III. 4:673; 16:369. R.H. 1889, p. 199; 1895, pp. 204, 205. M.D.G. 1898:349. S.H. 2:523. Gn. 24, p. 490. G. 30:325; 36:657. G.W. 5:259.

ALFRED REHDER.

PHILODÉNDRON (Greek compound for *tree-loving*). *Araceæ*. Shrubby or tree-like ornamental plants, usually climbing, rarely arboreous.

Internodes more or less elongated: lvs. from entire to bipinnatifid: fls. monoecious, on spadices, with no perianth, the sterile with 2-6 stamens united into a sessile obpyramidal body, the pistillate fls. with a 2-10-loculed ovary and some staminodia, the berries inclosed in the involute spathe.—The species are all Trop.

American. They are monographed by Engler in *Das Pflanzenreich*, hft. 60 (IV. 23 Dd) 1913, who accepts 222 species. Some of them are prominent in tropical plantings.

Only a few philodendrons can be grown to have an ornamental appearance in a small state. One which goes under the name of *P. elegantissimum*, with finely cut leaves, makes a good pot specimen, although it will reach considerable height when suitable opportunities are afforded. The same may be said of *P. Selloum*, a beautiful species with pinnatifid leaves. The arborescent kinds should have a very porous rooting medium and copious supplies of water while in active growth. When climbing, they must have provision made for the roots, which are produced along the stems. Some of the species do well climbing up the stems of tall palms, such as arenga and livistona; otherwise dead trunks of tree ferns make admirable rooting substances for the roots to penetrate and cling to. Propagation is by division of the climbing stems. *P. elegantissimum* is an unidentified trade name.

A. Lvs. bipinnate.

B. Terminal lf.-segms. 3-lobed, the lobes unequal.

Selloum, C. Koch (*P. Selloum*, Hort.). Blade pinnatisect, the segms. again pinnate or lobed; terminal segms. 3-lobed, the cuspidate middle lobe about equaling the obtuse lateral ones: spathe slightly cuspidate, its tube longer than the ovate hooded blade, green without, white within. Distinguished from *P. bipinnatifidum* by the very numerous parallel translucent spots, which are visible on both sides of the lf. and are often excurrent on the margin. Brazil to Paraguay. B.M. 6773. G.W. 10, p. 211.

BB. Terminal lf.-segms. 3-5-lobed, the middle lobe much longer than the lateral ones.

bipinnatifidum, Schott. Blade pinnatisect, the segms. again pinnate or lobed; terminal segm. 3-5-lobed, the middle lobe ovate-lanceolate, acute, much longer than the obtuse lateral ones: spathe oblong-ovate, its tube scarcely distinct from its blade, purple without, white within. S. Brazil.—Does well in the open in S. Calif.

AA. Lvs. simple.

B. Lf.-blade linear or lanceolate.

crassinervium, Lindl. Climbing: lvs. linear to lanceolate-acuminate, the midnerve very thick and inflated: spathe obtuse and hooded, apiculate at the tip. Brazil. B.R. 1953.—**P. nobile**, Bull, is like this but larger: lvs. long-oblancoate, large, coriaceous, and shining, obtuse or short-acuminate, narrowed at base: tube of spathe rosy crimson inside and outside, the limb white inside and spotted outside. Guiana.

BB. Lf.-blade sagittate.

speciosum, Schott. St. tall, arborescent: petioles terete at the base, concavo-convex above, twice as long as the midrib; blade triangular-oblong-ovate, bright green, acuminate, deeply sagittate, the basal lobes rhomboidal, obtuse, abruptly narrowed on the inner side above the middle: spathes thick, green with purple margins; spadix finger-shaped, shorter than the spathe. S. Brazil.

BBB. Lf.-blade oblong to ovate-cordate.

c. Color of lvs. milky white above, with reddish veins.

Sôdiroi, Hort. Lvs. cordate, ovate, milky white with reddish veins above; petiole cylindrical, pink. *P. Sodi-roanum*, Engler, is a different plant, apparently not in cult.

cc. Color of lvs. some shade of green above.

d. Petioles tomentose.

verrucosum, Mathieu (*P. Cárderi*, Hort. *P. Lindenii*, Hort.). St. long, branching, climbing, ashy gray, scabrous, angular-cylindrical, swollen at the nodes; internodes 3-6 in. long: petioles stout-cylindrical or somewhat angled, bright metallic red, covered with soft, erect, twisted, fleshy bristles and greenish hairs 4-6 in. long; blade glabrous, green above, brilliantly polished, or with paler lines and immersed nerves, bright green beneath with salmon-violet lines between the lateral nerves, 6-8 in. long, 4-6 in. wide, ovate-cordate, the semicircular basal lobes one-third as long as the slightly undulate apical one. Costa Rica southward. I.H. 18:79 (as *P. daquense*).

DD. Petioles glabrous.

gigantæum, Schott. Climbing: petioles 3 ft. long, thick, cylindrical; blade cordate-ovate, 24-28 in. long, 16-20 in. wide, the basal lobes slightly introrse, semi-ovate or obliquely semicircular, one-fourth as long as the apical one, separated by a broad parabolic sinus: spathe-tube 2 in. long, oblong, purple; spadix very thick. Trop. Amer.

Imbe, Schott (*P. Sellowianum*, Kunth). Branches rusty purple: petioles of young plant semi-cylindrical, terete, sparsely brown-spotted, $1\frac{1}{2}$ -2 times longer than the midrib; blade like parchment, cordate-oblong, the oblong basal lobes one-half as long as the apical, separated by a wide parabolic sinus, retrorse

or subintrorse; apical lobe cuspidate: spathe green outside, red within, its broadly ovate blade dirty yellow; spadix shaped like a finger. S. Brazil. The Mexican *P. sanguineum* has been called *P. Imbe* in gardens. *P. sanguineum* differs in having more elongated lvs. which are red beneath.

spectabile, Lind. Large, of vigorous habit: lvs. 12-15 in. long, nearly as broad, silky or velvety green.

Andreanum, Devans. Lvs. rather large, cordate-ovate, with short basal lobes, bronzy green. Colombia. R.H. 1886:36. R.B. 13, fig. 30.—Sparingly grown. Looks like a narrow-ld. anthurium.

P. calophyllum, Brongn. (*P. nobile*, Bull, in part). Lvs. tufted, 2-3 ft. long, 5-6 in. broad at middle, linear-oblong, acuminate, shining above, the costa very thick at base, with linear depressions: spathe pale yellowish green outside, inside bright carmine with white margin. N. Brazil. B.M. 7827.—*P. canifolium*, Mart. Lvs. thick, coriaceous, oblong, shining above, the costa semi-terete: spathe cymbiform, green outside, purple, green and white inside. Brazil.—*P. Corsonianum*, Makoy. Lvs. $1\frac{1}{4}$ -2 $\frac{1}{4}$ ft. long, 11-18 in. broad, shortly pinnatifid, deep green above, beneath purple with green veins: spathe with a purple-crimson spotted tube, the limb light green with red spots outside, the inside carmine with darker spots. Hybrid. B.M. 8172.—*P. Devansayanum*, Lind., is a scandent species with rather small glossy green lvs. which, even to the petioles, are blood-red when young. Peru. I.H. 42:48.—*P. Duvinieri*, Hort. Lvs. broadly and deeply lobed. Brazil.—*P. erubescens*, C. Koch. Climbing: lvs. elongated ovate-triangular, 6-8 in. long, 4-6 in. wide: spathe black-purple.—*P. Glaziouii*, Hook. f., is a climber something like *P. crassinervium*: lvs. oblong-acute, deep green, 12-18 in. long, 3-5 in. broad: spathe open, yellowish,

2906. *Phlebodium aureum*.

crimson within the tube. Brazil. B.M. 6813.—*P. Ilsemanii*, Hort. Lvs. oblong, cordate, dark green, splashed or marbled with white, and sometimes tinged rose-pink. G.C. III. 43:289.—*P. imperiale* is mentioned in European trade-lists. Engler accounts for only one *P. imperiale* (of Schott) and that he makes a synonym of *P. asperatum*, Koch. Sander & Co. advertise *P. imperiale* var. *Lauchiana*: "a lovely trailing stove foliage plant, which is admirably adapted for growing on pillars or wire shapes. It is quite distinct from and greatly superior to the well-known *P. imperiale*. The habit is much more graceful, the heart-shaped foliage smaller and more elegant. Down the center, from either side of the broad light green midrib, extend irregular blotches of dark green, projecting into a clear glaucous color, the edges of which are relieved by green blotches. The bases of the petioles bear bright red and green phylloides." *P. asperatum* is a short-jointed climbing Brazilian species with cordate-ovate entire dull green lvs.—*P. Mamei*, André, Lvs. cordate-ovate, acute, variegated with white: spathe partly open above and whitish, the tube blood-red. Ecuador. R.H. 1883, p. 104 and 492; 1897, p. 573. I.H. 43:66.—*P. peritum* is *Monstera deliciosa*.—*P. Simsii*, Kunth. Lvs. coriaceous, elongated triangular-sagittate, long-cuspidate, up to 20 in. long: spathe outside black-purple on the tube, yellowish on the limb. Guana. B.M. 2643.—*P. tripartitum*, Schott. (Anthurium insignis, Mast.). Lvs. 3-parted, 6-7 in. long: spathe-tube oblong, the blade whitish, ovate, shortly acuminate. Venezuela.—*P. Warszewiczii*, C. Koch. Lvs. triangular-sagittate, bipinnatifid, primrose, the lateral primary segms. 5-8 in. long. Cent. Amer. G.W. 10, p. 211. Gt. 59, p. 23.

GEORGE V. NASH.†

PHLEBODIUM (Greek, *a vein*). *Polypodiaceae*. A genus of ferns related to *Polypodium* and sometimes united with it, but differing widely in the venation, which is broken up into ample areoles, each of which contain 2 or more free veinlets which bear the sori on their united tips.

aureum, R. Br. (*Polypodium aureum*, Linn.). Fig. 2906. Rootstocks thick, creeping on surface, densely covered with bright yellowish scales: lvs. 2-4 ft. long, deeply pinnatifid, the lobes 5-9 in. long, $\frac{1}{2}$ -1 in. wide, with numerous bright yellow sori. G. 37:405.—A rich ornamental species of easy cult. from Trop. Amer. with glaucous green lvs. It produces, however, but a small number of lvs. to a plant. In Fla. it grows on palmettos. *Polypodium Mandaianum* of the trade is a wavy-lvd. form, which originated as a spore sport of the species, *P. aureum*. It develops lvs. of great beauty, which last for a long time on or off the plant. Cut off, they are used for florists' decorations. *Polypodium Schneideri*, Hort., is said to be a hybrid of *P. aureum* and *Polypodium vulgare*.

P. glaucum var. *Mayii* or *P. Mayii*. See Phymatodes.

L. M. UNDERWOOD.

R. C. BENEDICT.†

PHLEUM (*Phleos*, an old Greek name for a kind of reed). *Gramineae*. Perennial grasses, of great agricultural value, but scarcely horticultural subjects.

Spikelets 1-flid., in a close cylindrical spike-like panicle; glumes 2, persistent, keeled, short-awned; lemma shorter, delicate, awnless.—Species 10, in temperate zones.

pratense, Linn. TIMOTHY. HERD'S-GRASS. Figs. 2907, 2908. Commonly cult. for hay and for pastures, either alone or together with red clover or other grasses. It was intro. into Md. about 1720 from Eu., where it is native, by Timothy Hanson, and hence called timothy. The other name is said to come from a man by the name of Herd, who found it growing in N. H. and began its cult. It is better adapted for hay than for pasture, and for the latter is suited to temporary rather than permanent pasture.

A. S. HITCHCOCK.

2907. *Phleum pratense*.—Timothy. To show habit of root and top.

PHLOGACANTHUS (Greek for *flame*, and *acanthus*). *Acanthaceae*. Glasshouse plants grown for the ornamental flowers.

Tall half-shrubby herbs with entire or somewhat toothed lvs.: fls. white, red or greenish in long terminal or short lateral spikes; calyx 5-parted; segms. linear, awnlike, acuminate; corolla-tube long, broad, curved; limb 2-lipped, upper lip erect, entire or 2-lobed; lower lip 3-parted; perfect stamens 2, inserted on the lower part of the tube; anthers with 2 parallel cells; ovary many-ovuled; caps. round or obtusely 4-angled.—Species 12-15, India, Malaya, to New Guinea. Several of the species have been more or less cult. at one time or another. Used like the others of the family as decorative pot-plants in the greenhouse. They require a rather warm, damp atmosphere and a soil rich in humus. Prop. by cuttings or seeds.

thyrsiflorus, Nees (*Justicia thyrsiflora*, Roxbg.). Shrub, 3-7 ft. high: lvs. 7 x $1\frac{1}{4}$ in., lanceolate, glabrous: fls. orange, in long, dense, villous thyrses; corolla $\frac{2}{3}$ in. wide, tubular, 2-lipped. India.—Cult. in S. Fla.

P. curviflorus, Nees. Shrub, 3-6 ft. high: lvs. large, elliptic, acute at both ends, toothed, glabrous: fls. yellowish, with an elongated corolla. Himalayas. B.M. 3783. H.U. 2, p. 259.

HEINRICH HASSELBRING.

PHLOMIS (old Greek name used by Dioscorides). *Labiatae*. JERUSALEM SAGE. Stout mostly tall plants sometimes grown in the open for the dense axillary whorls of rather large yellow, purple or white flowers.

Plants more or less woolly, some of the species conspicuously white-woolly, shrubs or perennial herbs: lvs. all alike, or the uppermost reduced to bracts: whorls many- or few-flid.; fls. sessile; calyx usually plicate, truncate or with 5 equal teeth; upper lip of the corolla (galea) broad and compressed or strongly concave, rarely narrow and falcate; lower lip 3-cleft and spreading; tube usually bearing a woolly ring inside; stamens 4, didynamous, ascending under the upper lip, one pair of filaments

often appendaged at base; style 2-lobed: nutlets 4, obovoid or ovoid, triquetrous, glabrous or pubescent.—Medit. region and to China, perhaps 70 species. Perhaps a dozen species have been cult., but they are rather coarse plants except for wild gardening and among shrubbery. They are of the easiest cult. Prop. by seeds, cuttings, and the herbaceous species by division. *P. tuberosa*, Linn., of Eu., has run wild sparingly in the E. It is a vigorous and hardy species, prop. by subterranean tubers.

A. Fls. yellow.

fruticosa, Linn. JERUSALEM SAGE. Shrub, 2-4 ft. high, divaricately much-branched, yellowish tomentose: lvs. ovate to oblong, rounded or wedge-shaped at the base, rugose, green above and white-tomentose beneath: whorls 20-30-flid., one or two at ends of branches; bracts broadly ovate or ovate-lanceolate: fls. yellow, showy. S. Eu. B.M. 1843. Gn. 79, p. 114. G. 7:177; 35:713.—In the E. it blooms from June to July. In S. Calif., it blooms in winter, and has the merit of withstanding drought and heavy sea winds. In New Eng. land it needs protection in winter.

lunarifolia, Sibth. & Smith. Undershrub, erect and branching, green but oppressed-tomentose, 6 ft.: lvs.

2908. *Phleum pratense*.—Timothy. ($\times \frac{1}{2}$)

oblong or ovate-oblong, obtuse at apex, narrowed at base, paler and almost hoary beneath, the lower ones long-stalked: fls. golden yellow, $1\frac{1}{2}$ in. long, in a showy terminal whorl or head 4 in. across with 2 pendulous floral lvs. beneath; bracts small, or orbicular; calyx $\frac{3}{4}$ in. long, 10-ribbed; corolla with villous 2-keeled galea, and large lower lip with 2 wings or lobes at end. Asia Minor. B.M. 7699.—A striking plant.

Lychnitis, Linn. **LAMP-WICK PLANT**. Somewhat woody, 2 ft., hoary: lvs. sessile and amplexicaul, oblong-linear, narrowed at both ends, white-tomentose beneath: whorls few-fld., much shorter than the floral lvs.; bracts broad at base; fls. yellow, the corolla twice longer than calyx. S. Eu. B.M. 999.—The specific name *Lychnitis* refers to the use of the slender radical lvs. as lamp-wicks.

viscosa, Poir. (*P. Russeliana*, Benth.). Shrubby, glabrous, but viscid above, with elongated branches: lvs. ovate and oblong-lanceolate, the lower ones petioled and strongly cordate at base; floral lvs. cuneate-lanceolate and acuminate, much surpassing the fls.: whorls many-fld., remote, with lance-linear rigid bracts; corolla yellow, twice longer than calyx, the galea emarginate, lower lip with broad lobe. Asia Minor. B.M. 2542 (as *P. lunatifolia* var. *Russeliana*).

AA. Fls. purple, or pinkish, at least inside.

tuberosa, Linn. Herb. 3-6 ft. high, nearly smooth, with thickened root: lvs. deeply cordate, ovate, petioled, crenate, the lower ones triangular-ovate and 6 in. or more long; floral lvs. 2-3 in. long, 6-8 lines wide, oblong-lanceolate: whorls 30-40-fld., bearing purple fls. that are white-bearded inside. S. Eu., E. and N. Asia. B.M. 1555.—Little planted; known mostly as a weedy naturalized species.

Herba-venti, Linn. Much-branched, 1-2 ft., hairy: lvs. oblong-lanceolate, or ovate-oblong, crenate, coriaceous, rounded at base, either canescent or green beneath: whorls 10-20-fld., much surpassed by the long floral lvs.; fls. purplish, tomentose on outside; galea much arched; lower lip short. Medit. B.M. 2449. G. 35:712.—The name *Herba-venti* means "wind herb." It is recorded that "when exposed to wind and rain, the leaves are apt to lose their softer parts, leaving merely a network of fibers, pervious to the wind, whence the old name of *Herba-venti*."

cashmeriana, Royle. Sts. several, stout, terete, densely white-woolly, 2-3 ft. high: lvs. linear-oblong, obtuse, rugose and crenate, cordate at base, pubescent above, the radical ones long-petioled: whorls many-fld., $1-1\frac{1}{2}$ in. diam.; bracts numerous, filiform, ciliate and tomentose; fls. pale purple; galea very large, tomentose but not fringed; lower lip very broad; calyx-teeth spine-like and half length of the tube. Afghanistan, Himalaya. B.R. 30:22. J.F. 3:284.

Sâmia, Linn. Pubescent, 2-3 ft., simple or sparingly opposite-paniculate-branched: lvs. ovate-oblong, cordate and somewhat acute, petioled, rugose and crenate, green above and tomentose beneath: whorls 10-15-fld., bracts many, linear, very acute; fls. hairy, greenish white outside, pinkish and purple-veined inside. Greece, Asia Minor. B.M. 1891. G. 35:711. L. H. B.†

PHLÓX (Greek for *flame*, once applied to species of *Lychnis*). *Polemoniaceæ*. Showy and popular flower-garden herbs, perennial and annual.

Erect or diffuse, tall or low, mostly perennial, glabrous, pubescent or hairy, a few of them woody at base but mainly herbaceous throughout: lvs. mostly opposite or sometimes the upper ones alternate, entire: fls. in bright colors, blue, red, blue-red, purple, white, in terminal cymes or thyrses; calyx narrow-tubular or sometimes nearly campanulate, 5-ribbed and 5-cleft, the lobes sharp-pointed; corolla convolute in bud, salverform, with a very slender tube and a flat-spreading 5-lobed limb, the lobes obovate or broader and some-

times notched; stamens 5, usually unequal in length or in point of attachment, usually included; ovary 3-celled, oblong or ovoid, the style slender: caps. 3-valved, the seeds 1 or few in each cell, usually 1.—Species 48 as defined by Brand in Engler's *Das Pflanzenreich*, hft. 27 (IV. 250), 1907, one of which is Siberian and the

others N. American, in woods and thickets and on prairies and plains, some of them alpine and arctic.

From a horticultural point of view, the phloxes may be thrown into five groups: (1) the annual phloxes, *P. Drummondii*; (2) the highly developed summer

perennial tall phloxes of nurseries and gardens, *P. paniculata* and *P. maculata*; (3) the moss pinks, *P. subulata* and its variants, useful as carpeters; (4) those useful in alpine and rock-gardening, although little employed for the purpose in America, represented by *P. multiflora* and the caespitose Rocky Mountains set which seems not to be in the lists; (5) the early blooming perennial woods and plains species not yet much domesticated but often naturalized in grounds, as *P. pilosa*, *P. divaricata*, and others. As a group, phloxes are amongst the most satisfactory of garden plants.

2909. Cultivated forms of *Phlox Drummondii*.

Their neat habit, bright-colored flowers, profuseness of bloom, and ease of culture make them favorites everywhere. Most of the domesticated kinds are summer bloomers, but *P. subulata* is spring-flowering.

The annual phloxes, derivatives of *Phlox Drummondii*, of Texas, have risen to first place as garden annuals. This species has been much modified by domestication, so that the named garden varieties are numbered by dozens. These garden forms differ in stature, color, size and shape of flower. Some are semi-double. An effort has been made to produce a yellow flower, but apparently a true yellow has not yet been secured. The colors run to the cyanic series, in many interesting variations. *Phlox Drummondii* is of the easiest culture. This fact, together with the profusion and long season of its bloom, is an important reason for its popularity. It blooms all summer and until frost if the stock and conditions are good. It needs a warm sunny place. It will grow even in poor soil, but in order to develop to its highest perfection it must have good soil and the individual plants must be given room (say 1 foot apart each way). Seeds are usually sown in the open as soon as the weather is settled; sometimes they are sown indoors, but the plants bloom so young that this is rarely practised. If the ground is poor and dry, the plants usually cease blooming by midsummer, but if plant-food and moisture are abundant they may be expected to continue their bloom until late autumn. To attain this result most perfectly, the old flower-

cluster should be removed; the plant is an end-bloomer, and when the terminal flower-cluster has matured the other shoots continue the growth and thereby provide a succession of bloom. This phlox has now varied so much under domestication that packets of mixed seed are likely to give tall and dwarf, large-flowered and small-flowered forms, with very unsatisfactory results. If mixed colors are desired, pains should be taken to secure seed that will produce plants of similar height and season. Some of the cheap seed may produce very disappointing plants even under the best conditions.

The summer perennial phloxes of gardens are of several races. They are probably the issue of *P. paniculata* and *P. maculata*, although their origin and characteristics need to be worked over. This group of plants is amongst the most showy of garden herbs. The terminal panicles have become 1 foot long in some forms, and as densely filled as a hydrangea. They are specially desirable when color display is sought in connection with formal or semi-formal designs, as on terraces and by balustrades. The colors are most frequent in reds, but there are many purple, white, salmon, and parti-colored varieties. The summer perennial phlox should have a rich and rather moist soil if it is to be grown to perfection. It should never suffer for moisture or food. Let each clump have a space, when fully developed, of 2 to 3 feet across. The plants as purchased from nurseries usually do not come into full floriferousness until their third year. For the highest satisfaction in blooms, the plants should be relatively young or at least often renewed by dividing the clump. The stool gradually enlarges outward. From the young vigorous shoots on the outside of the clump the new plants should be reared, if one desires to propagate the variety to any extent. Old stools should be taken up every year or two, and divided and transplanted. This work is performed in the fall, after the growth has ceased. By this process, the plants do not become weak and root-bound. Inferior and vigorous seedlings are often allowed to grow about the old plant, causing the named varieties to "run out." The modern varieties should not remain undisturbed for more than three or four years. One of the requisites is to secure in the first place stock that is strong and healthy. Phloxes usually bloom in early summer and midsummer, but if the tips of the shoots are pinched out once or twice in early summer, the bloom may be delayed until late summer or autumn. Named varieties are propagated by side shoots and by cuttings of well-maturing shoots. Seeds give new and often interesting forms.

A. Species annual, pubescent: upper lvs. often alternate.

1. *Drummondii*, Hook. Figs. 2909, 2910. Erect branching annual, more or less villous and viscid, 6-18 in. tall; lvs. alternate, oblong-acute or lanceolate, the upper ones more or less clasping; fls. showy, in broad mostly flat-topped cymes, the calyx-lobes long and narrow and spreading or recurving in fr., the corolla-lobes broad-ovate. Sandy soils. Texas. B.M. 3441. B.R. 1949.—This is the original of the common annual garden phlox, now cult. in numerous varieties. The seeds were received in England in the spring of 1835, from Texas, having been collected by Drummond. In Oct. of that year it was described and figured in B.M., by W. J. Hooker, as *Phlox Drummondii*. The fl. was described as "pale purple without, within, or on the upper side, of a brilliant rose-red or purple, varying exceedingly on different individuals in intensity, and in their more or less red or purple tinge: the eye generally of an exceedingly deep crimson." Lindley described and figured it in B.R., for 1837, describing the fls. as "either light, or deep carmine, on the inner surface of their corolla, and a pale blush on the outside, which sets off wonderfully the general effect. A bed of this plant has hardly yet been seen; for it is far too precious and uncommon to be possessed by any one, except in small quantities; but I have had such a bed described to me, and I can readily believe that it produced all the brilliancy that my informant represented."

The annual garden phloxes are now of many kinds and races. They may be thrown into two groups: Var. *rotundata*, Voss, with petals large, broad, and entire or nearly so, making a circular outline; var. *stellaris*, Voss, the star phloxes, the petals narrow, cuspidate or variously fringed or cut. To the former belong such races or forms as *Heynholdii*, *Deppel*, *Isabellina*, *formosa*, *splendens*, *hortensiaeflora* or *verbenæflora*, *grandiflora*. With the latter (var. *stellaris*) may be classed *cuspidata*, *fimbriata* or *laciniata*, *stellata*. There are also dwarf and intermediate races of annual phloxes as well as semi-double forms. For a discussion of the heredity of color in *Phlox Drummondii*, see Gilbert, Journ. Agr. Research, July, 1915.

There are several annual phloxes in Texas, some of them perhaps to be regarded as variants of *P. Drummondii*. *P. villosissima*, Small (*P. Drummondii* var. *villosissima*, Gray), is very villous and viscous, the fls. large and more scattered, the lvs. mostly opposite and the blade thick and bristly: corolla pale lavender, the

2910. Quedlinburg or star phlox. A horticultural form of *Phlox Drummondii*. (Natural size)

limb $\frac{1}{2}$ -1 in. broad, lobes broad-obovate and often abruptly pointed. *P. tenuis*, A. Nelson (var. *tenuis*, Gray) is small and slender, not villous, glabrous or slightly pubescent: lvs. mostly alternate, the blades thin and linear or linear-lanceolate: fls. lavender, small, the limb about $\frac{1}{2}$ in. across, lobes rhombic-ovate and acute. *P. áspera*, A. Nelson. With short rigid hairs: lvs. opposite, the blades thick, narrow-lanceolate to linear: calyx and pedicels glandular, the calyx-lobes awned; corolla violet, the tube glandular-pubescent; lobes cuneate-obovate, about $\frac{1}{2}$ in. long, mucronate. *P. Roemeriana*, Scheele. Glabrate or somewhat hirsute: lvs. mostly alternate, spatulate-oblong or lanceolate, sessile, usually acute or acuminate: fls. solitary or few, pink or rose-colored; corolla-tube not surpassing the calyx (in this differing from the other annual Texan phloxes); limb of corolla less than 1 in. across, the lobes roundish obovate and entire; ovules 4 or 5 in each cell.

AA. *Species perennial, of various habit, either pubescent or glabrous.*

B. *Flowering st. erect and usually stiffish* (Nos. 2-9).

C. *Plant mostly glabrous, at least below (exceptions in variety of No. 5).*

D. *Infl. large and thyrselike: plants tall.*

2. *paniculata*, Linn. (*P. decussata*, Hort. *P. acuminata*, Pursh. *P. cordata*, Ell. *P. undulata*, Ait.). SUMMER PERENNIAL PHLOX of gardens, in many forms. Fig. 2911. Plant stout and erect, 2-4 or 6 ft., glabrous: lvs. thin, oblong-lanceolate and mostly tapering at the base, acute or acuminate: calyx-teeth awl-like. Woods, Pa.,

2911. Summer perennial phlox, of the *P. paniculata* and *P. maculata* group.

west and south. Summer. B.M. 1880.—The parent of the greater number of perennial phloxes of gardens, although some of these may be hybrids with the next. "Fls. pink-purple, varying to white," according to Gray. In cult. varying much in color. This plant, in several

2912. *Phlox glaberrima*. ($\times 1\frac{1}{2}$)

forms, persists about old homesteads and sometimes becomes naturalized. *P. amplifolia*, Brit., with st. villous, glandular above, lvs. broader, ranging from Ind. to Tenn. and Mo., is considered by some to be a form of *P. paniculata*.

3. *maculata*, Linn. (*P. pyramidalis*, Smith. *P. reflexa* and *P. penduliflora*, Sweet). SUMMER PERENNIAL PHLOX. Slenderer, and mostly less tall, usually with purple-spotted st.: lvs. very smooth and usually thicker than those of the above, the upper ones usually clasping: calyx-teeth short: fls. as in above. Range of the last, and in cult., but less important horticulturally than *P. paniculata*. Summer. Var. *suaveolens*, Brand (var. *candida*, Michx. *P. suaveolens*, Ait. *P. tardiflora*, Penny. *P. longiflora*, Sweet. *P. alba*, Moench). St. glabrous, not spotted: fls. sweet-scented, white.

The foregoing treatment of the synonymy of the two species entering into the origin of the summer perennial phloxes is essentially that of Gray. Brand removes a number of these names into a separate category comprising a range of hybrids, and accounts for other old horticultural names, as follows:

3a. *paniculata* $\times$ *maculata*, Brand. *P. pyramidalis*, Smith; *P. decussata*, Lyon; *P. reflexa*, *P. excelsa*, *P. Wheeleriana*, *P. Shepherdii*, *P. penduliflora*, Sweet; *P. missoirica*, Salm-Dyck; *P. omniflora*, *P. atrocaulis*, *P. Ingramiana*, *P. pulchella*, *P. Vernoniæna*, Hort.; *P. Youngii*, *P. Coldryana*, Court.; *P. speciosissima*, Maund; *P. Bridgesii*, *P. Broughtonii*, Marn.; *P. Van Houttei*, *P. Marianna*, Lindl.; *P. insignis*, De Jonghe; *P. Oldryana*, Walp. Several other old Latin names are also referable to this hybrid group.

DD. *Infl. small and loose or flat-topped: plants lower.*

4. *ovata*, Linn. (*P. carolina*, Linn. *P. triflora*, Maund). A foot or two tall, the sts. erect from a short decumbent base, glabrous or very nearly so: lvs. narrow-ovate to oblong-lanceolate, the lower ones tapering to base and the upper ones somewhat clasping: fls. pink or light red, about 1 in. across, the straight or slightly curving tube twice or more longer than the rather short and broad calyx-teeth. Pa. to Ala., mostly in elevated regions. B.M. 528. Gn. M. 2:168.

5. *glaberrima*, Linn. Fig. 2912. Differs in somewhat taller growth, linear-lanceolate to narrow-lanceolate taper-pointed firm nearly veinless lvs. which have revolute margins, and in the narrow very sharp-pointed calyx-teeth. Va. to Wis., and south to Fla.

Var. *suffruticosa*, Gray (*P. suffruticosa*, Vent. *P. nitida*, Pursh). Stiffer, sometimes pubescent above: lvs. considerably broader: fls. varying to flesh-color. Ga. and Tenn., south and west. B.M. 1344 (as *P. carolina*), and B.R. 68.

2913. *Phlox divaricata* ($\times \frac{1}{2}$).

cc. Plant distinctly hairy or pubescent (exceptions in No. 9).

d. Sterile, prostrate or running shoots arising from the base of the plant.

6. *divaricata*, Linn. (*P. canadensis*, Sweet). WILD SWEET WILLIAM. Fig. 2913. Sts. slender, pubescent, 10-18 in. tall: lvs. varying from linear-oblong to ovate-lanceolate, mostly acute: fls. in small cymes terminating short branches, 1 in. across, blue or pinkish blue, handsome and somewhat fragrant, the corolla-lobes often notched, the calyx-lobes narrow and subulate. Woods and copses, in lowish grounds. Que., west and south, to Fla. and La. B.M. 163. G.F. 7:256 (reduced in Fig. 2913). Gn. 60, p. 251; 76, p. 45. G.L. 18:335. G.W. 2, p. 555. R.B. 24:185. Gn.W. 23:433. Gn.M. 2:167.—A very attractive early spring fl., often coloring the floor of woods. Prefers rich soil. Var. *Láphamii*, Wood. Lvs. ovate: fls. bright blue; petals obtuse and entire. This name is listed abroad; plant said to be stronger-growing and with longer-blooming season than the species. G.M. 55:556.—*P. divaricata* has received considerable attention from cultivators abroad.

7. *stolonifera*, Sims (*P. reptans*, Michx.). Low and weak, the flowering sts. reaching 6-12 in., the sterile ones long and prostrate, the plant thinly glandular-hairy: lvs. short-ovate or obovate, more or less obtuse: fls. few in each cyme, purple or violet, the lobes mostly

entire, the calyx-lobes narrow and subulate. Pa. and Ky. to Ga., mostly in the upper regions. B.M. 563. Var. *véna*, Hort. (*P. véna*, Hort.), has rose-colored fls. with dark purple throat; a garden form.

dd. Sterile prostrate shoots none.

8. *amœna*, Sims (*P. Wálteri*, Chapm. *P. involu-crata*, Wood). Sts. 6 in. or less high from a decumbent base, pubescent or hairy: lvs. numerous, mostly in rosettes at the base, few on the flowering sts., small, oblong-lanceolate to linear-oblong, mostly obtuse but sometimes nearly or quite acute: fls. numerous for size of plant, purple, pink or white, lobes usually entire, calyx-lobes narrow and sharp-acute. Dry lands, Va. to Ky. and south. B.M. 1308. G.M. 56:157. Var. *foliis variegatis*, Hort., with lvs. variegated, is listed.

9. *pilosa*, Linn. (*P. aristata*, Michx. *P. cuspidata*, Scheele). Sts. slender but erect, 2 ft. or less tall, pubescent or hairy (nearly glabrous forms occur): lvs. small, linear or linear-lanceolate, widest near the base, acuminate: fls. numerous in rather loose cymes, varying through purple, pink and white, the lobes entire, the calyx-lobes awn-like. Dry fields, woods, Ont. and Man. to Fla. and Texas, growing as far east as N. J. B.M. 1307. L.B.C. 1251, 1731. G.L. 27:117. Gn.W. 23:495.

BB. Flowering sts. diffuse and branching, often creeping, low, sometimes caespitose: plants of more or less tufted habit.

c. Corolla-lobes 2-3-parted or very strongly notched.

10. *bifida*, Beck. Low, the sts. stiff and sometimes almost woody and often 1 ft. long and rising 3-8 in. from the ground, minutely pubescent: lvs. linear and rigid, 2 in. or less long: fls. scattered, violet-purple, the lobes 2- or 3-cleft as far as the middle or farther into narrow spreading segm. Prairies, Mich. to Mo. and Tenn.—Rarely cult.

11. *Stellaria*, Gray. Fig. 2914. *Stellaria*-like: glabrous: lvs. linear, sparingly ciliate toward the base: fls. scattered, usually long-peduncled, pale blue to whitish, the lobes cleft only at the apex into short oblong parts. Lexington, Ky., to S. Ill. and Tenn. G.F. 1:257 (adapted in Fig. 2914).—How much, if any, of the *P. stellaria* of the trade is this species and how much is forms of *P. subulata*, is to be determined.

cc. Corolla-lobes shallow-notched or entire.

d. Peduncles usually bearing few to several slender-pedicelled fls.

12. *subulata*, Linn. (*P. setacea*, Linn.). GROUND PINK, MOSS PINK. Fig. 2915. Tufted or matted species, in many forms, the depressed sts. more or less

2914. *Phlox Stellaria* ($\times \frac{1}{2}$).

pubescent: lvs. crowded or fascicled (except on the flowering sts.), narrow-linear to linear-lanceolate, very sharp and usually stiff, ciliate: fls. nearly 1 in. across, light blue, pink or white, in small clusters standing 2-6 in. above the ground, the lobes obovate or entire. Dry banks and fields, N. Y., west and south, reaching Fla.; run wild in patches along many roadsides, in cemeteries, and elsewhere. B. M. 411 and 415. Gn. 67, p. 218; 71, p. 166; 75, p. 29. F. W. 1878, frontis. Gn. M. 2:167. G.L. 22: 358.—A much-prized old garden plant, useful for colonizing where it is desired to cover the earth with a mat. It blooms profusely in spring. The garden forms are many, as: Var. *nivalis*, Hort. (*P. nivalis*, Lodd.), white-fl., style short; ovules commonly 2 or 3 in each cell. L. B.C. 8:780. Var. *aristata*, Hort. (*P. aristata*, Lodd.), has fls. pure white, sometimes lilac-tinted; ovules 1 in each cell. L. B.C. 18:1731. Var. *Nelsonii*, Hort., (not *P. Nelsonii*, Brand), white, with rose-red eye; compact. G.W. 15, p. 430. Gn. 75, p. 275. Var. *Héntzii*, Voss (*P. Héntzii*, Nutt.), lobes entire or nearly so, white, lavender or purple. Southern states. Var. *annulata*, Hort., whitish blue, with purple ring. Var. *atropurpurea*, Hort., rose-purple with crimson ring. Var. *grandiflora*, Hort., fls. large, red; plant dwarf. Var. *stellaris*, Hort., with star-like white fls. in profusion. Var. *cærulescens*, Hort., with bluish fls. Var. *pallida*, Hort., large-fl., rose-colored shaded lilac. Var. *frondosa*, Hort., vigorous form; fls. pink with dark center. Var. *lilacina*, Hort., compact, lilac-fl. G.C. III. 41:383. G.M. 55:283.—Some of the foregoing forms are described or listed as if derived from *P. Stellaria*; but whether from the species *P. Stellaria*, Gray, or the race of *stellaria* or *stellaris* of *P. subulata*, is not always clear.

DD. *Peduncles chiefly axillary and mostly 1- to 3-fl., or the fls. nearly sessile.*

E. *Lvs. crowded or fascicled: plant forming a mat or tuft.*

13. *Douglasii*, Hook. Very low and densely tufted, pubescent or nearly glabrous: lvs. very narrow, pointed, the margins at base often ciliate: fls. small and short-stalked, purple, lilac or white, about 1/2 in. across, the lobes

obovate and entire, the tube little exceeding the calyx. Utah and Mont., west. Gn. M. 2:168.

14. *multiflora*, A. Nelson. Somewhat similar in habit to *P. subulata*, producing large fls. in spring so freely as to hide the foliage: caespitose, the branching prostrate base woody, the herbaceous nearly erect shoots 2-4 in. high, the branches simple and 1-fl.: lvs. broad-linear, glabrous, opposite or fascicled: fls. rose, lilac or lavender, fragrant; tube of corolla exceeding calyx, the lobes 3/4 in. long, obovate and entire. Foothills Colo. to Mont.—Offered in the W.

EE. *Lvs. little if at all fascicled: plant only loosely tufted.*

F. *Style nearly or quite equaling the corolla-tube.*

15. *adsurgens*, Torr. Fig. 2916. Sts. 3-6 in. long, diffuse and ascending, glabrous except the peduncles and calyx: lvs. ovate-lanceolate or

ovate, acute, less than 1 in. long: fls. rose-colored or whitish, nearly or quite 1 in. across, the obovate lobes entire, the tube nearly twice longer than calyx. Ore., in Cascade Mts. G.F. 1:66 (adapted in Fig. 2916).

FF. *Style very short.*

16. *speciosa*, Pursh. Variable in size, sometimes ascending to 3 ft., more or less glandular above: lvs. 2 in. or less long, linear to lanceolate, the uppermost broad at base: fls. rose-pink or whitish, in corymbs, the lobes obovate, the tube little surpassing the calyx. Ariz. and Calif. to Wash., in many forms.

17. *nana*, Nutt. (*P. triovulata*, Thurb.). Fig. 2917. Only a few inches high, glandular-pubescent: lvs. 2 in. or less long, linear, sometimes alternate: fls. light red or rose to white, scattered or somewhat corymbose, about or nearly 1 in. across, the lobes usually entire and roundish, the tube somewhat surpassing the calyx. Texas to Ariz. G.F. 1:413 (adapted in Fig. 2917).

Many other species may be expected to appear in the lists of dealers, and there are many Latin names of domestic forms of *P. Drummondii*, *P. paniculata-maculata*, *P. subulata*.—*P. Arendsii*, Hort. A summer-flowering dwarf perennial phlox originating with G. Arends, Germany, said to be hybrid of *P. divaricata* (*P. canadensis*) and *P. paniculata* (*P. decussata*). Sts. stiff and wiry, about 2 ft. high: fls. lavender, mauve and violet, in flattish or rounded heads.—*P. Brittonii*, Small. Of the *P. subulata* set, growing on dry mountain slopes in Va., W. Va., N. C.: corolla-lobes deeply emarginate rather than shallowly emarginate or entire as in *P. subulata*: upper part of plant glandular: fls. mostly white, with 2 magenta spots at base of lobes: lvs. numerous, subulate or nearly so.—*P. carnea*, Sims. Probably a hybrid of *P. maculata* and *P. glaberrima*: 1 1/2-3 ft., erect, st. not spotted: lower lvs. narrow-lanceolate to linear, the upper ones oblong: fls. rose-colored to purplish, in terminal corymbs, on very short pedicels. Southern states. B.M. 2155. L. B.C. 8:711.—*P. criterion*, Miell. Like *P. Drummondii*, but peren-

2915. *Phlox subulata*. (× 3/4)

2916. *Phlox adsurgens*. (× 1/2)

2917. *Phlox nana*. (× 1/2)

nial: perhaps hybrid of *P. paniculata* and *P. Drummoudii*. F.S. 8:800.—*P. Lindsayiana*, Hort., apparently of the *P. subulata* group, said to be a hybrid and useful for rockery and border.—*P. sibirica*, Linn. The one Asian species, occurring also in Alaska: a low loosely cespitose species, 6–9 in. high, white-fl'd., mostly villous-pubescent: lvs. narrow-linear: corolla-lobes obovate or emarginate.

L. H. B.

PHŒNICOPHŒRIUM: *Stevensonia*.

PHŒNIX (Theophrastus gave this name to the date palm, perhaps thinking of Phœnicia, where the Greeks were supposed first to have seen it, or of the Phœnician purple, or of the fabled bird of Egypt). *Palmaceæ*. A distinct and exceedingly useful genus of palms, planted for fruit, ornament and shade.

Palms with sts. spineless (in many species the lower lfts. are reduced to long stout spine-like processes), without trunks, or with stout or slender, short or long, erect or inclined trunks, often cespitose, clothed above with the persistent bases of the lvs.: lvs. terminal, spreading, recurved, unequally pinnate; segms. somewhat fasciculate or almost equidistant, elongated-lanceolate or ensiform, acuminate, rigid, inserted by the wide base; margins entire or folded on their entire length; rachis laterally compressed, convex on the back; petiole plano-convex, usually spiny, with very short rigid pinnae; sheaths short, fibrous: spadices usually many, erect or nodding in fr., or pendent, appearing among the lvs.: peduncle strongly compressed: branches usually somewhat umbellate: spathe basilar, entire, long, compressed, 2-edged, coriaceous ventrally and at length dorsally divided; bracts usually obsolete; fls. small, leathery, yellow: fr. a berry or drupe, oblong, orange, brown or black, the seed always grooved.—Species 10–12, perhaps more, in Trop. and Subtrop. Asia and Afr. The botanical monograph of the genus *Phœnix* by Beccari (in *Malesia* 3:345) admits only 10 species, although there are about 60 names. Such a "lumping" of species is very unwelcome to the horticulturist, and it is probable that nearly all the synonyms cited below represent forms that are abundantly distinct for horticultural purposes. The following account of the genus is adapted from the work of Beccari, especially the Asiatic species. A good horticultural appreciation of *Phœnix* is that by William Watson, of Kew, in G.C. III. 9:234, 298, from which liberal extracts are made below. *Phœnixes* differ from all other pinnate-lvd. palms in having the lvs. folded upward and lengthwise, and in the peculiar form of the seed, as seen in the date stone. The plants are either male or female.

The fruits of only one species are used for food; viz., *P. dactylifera*. (For date-culture, see *Date*.) In England, only *P. rupicola* ranks among popular decorative plants. Of all palms, the cultivated species of *Phœnix* are the most difficult to define. Many hybrids have been raised in the gardens of the Riviera, where several species flower and fruit every year. It is almost impos-

sible to keep these pure. Kerchove records the wonderful fecundity of a *phœnix*; *P. reclinata* at Nice fertilized with pollen from *P. tenuis*, *P. reclinata* and *P. pumila* produced 20,000 seeds. The raising of *phœnixes* from seed is done on a large scale on the Riviera. The seeds are sown in beds in the open and the seedlings transplanted into shallow trenches like celery, so that the trenches may be regularly flooded during the summer drought. Next to the coco-palm, the date is one of the most useful trees in the world. *P. canariensis* is the noblest of all *phœnixes*, and one of the most majestic palms in cultivation. Its rate of growth is astonishing: a tree supposed to be only ten years old had a trunk 4 feet high, 3 feet in diameter at the base, with about one hundred leaves forming a head 25 feet across. Another specimen of about the same size bore eight bunches of fruit, each weighing about fifty pounds. *P. sylvestris* is the wild date of India, where it is cultivated for its

sap, which yields sugar and "toddy." The trunk attains a height of about 4 feet when seven years old, and it is then tapped by cutting a notch in the stem at the top and catching the sap as it runs out. The tree continues to yield annually fifteen to eighteen gallons of sap for twenty to twenty-five years, or eight pounds of sugar a year. Many thousand tons of date-sugar are produced every year in Bengal alone from this and other palms. "*P.*

reclinata and *P. spinosa* are united under the former name by Beccari. Taking the dwarf, cespitose, shiny-leaved elegant plant found in Cafraria as far south as Gra-

hamstown, and comparing it with the tall, solitary stem, huge-headed, gray-green-leaved plant of the tropical regions of Africa, it is difficult to believe that they are merely forms of one species." An interesting novelty in *phœnix* is the plant known as *P. Roebelenii*, the pygmy *phœnix* (Fig. 2919.) Specimens twenty to thirty years old have stems not over 2 feet high. Watson says: "It is by far the smallest of all the many kinds of *phœnix* known, and is also exceptional in the form of its stem and in the elegance and soft texture of its bright green leaves." Watson adds that

it deserves to rank with *Cocos Weddelliana* and *Geonoma gracilis* for usefulness in a small state. This palm suckers freely and in a wild state grows in clumps. *P. Roebelenii* is often treated as a variety of *P. humilis*; but Watson and others think that it is a distinct species and that in the form and texture of its leaves it resembles *P. rupicola* more than any other species. Because of its distinctness horticulturally and the general uncertainty in the genus, it is advisable to keep *P. Roebelenii* distinct for the present at least. It is native in the Laos region of Indo-China, where it was discovered by Mr. Roebelin, who went there regularly every year and exported the seed to Europe by way of Bangkok. It is specially abundant in the Nam Ou River Valley, and occurs also toward Pac Lay.

The botany of *Phœnix* is much confused, and no one knows what is planted in this country under the different names. The species hybridize freely, and it is probable that most of the cultivated forms are hybrids

2918. *Phœnix Roebelenii*.

of various mixtures. While some of the garden names are considered by botanists to be synonyms, they may represent distinct plants to the horticulturist. Any treatment of Phœnix as represented in North America must now be tentative.

Cultivation of phœnix.

In Florida.—In moist land no special care is necessary in setting out these palms. All they require is shade after the planting of small specimens, and a mulch of old grass or stable-manure. They must be frequently tilled and fertilized. Always use a fertilizer rich in ammonia while they are making their growth. In autumn, a fertilizer containing 10 or 12 per cent of potash should be used, with a good addition of phosphoric acid. This will make the plants more hardy to endure occasional cold spells. On high dry pineland, holes 3 to 5 or 6 feet deep and wide should be dug for the large-growing species, and these holes should be filled with old stable-manure, bones, muck, and clay. Plant in a saucer-like depression about a foot deep in the center, and apply a heavy mulch of old stable-manure after the plant has been set out. If stable-manure is not at hand, old leaves and grass may be used instead. Small plants should be well shaded for a year or so, and they also should be kept constantly moist during the dry season. All hardy palms should be set out in November, December, and January. One is not likely to be successful in transplanting them in the dry season from March to June.—In Florida, experience has been had with plants under the following names: *P. canariensis* is the most beautiful as well as the most massive of the tall-growing single-stemmed species. The trunk in young specimens is immense. It is a fast grower in rich moist soils, but very slow and unsatisfactory in high dry sandy lands. It is excellent

2919. Phœnix Roebelenii of horticulturists, considered by some botanists to be a form of *P. humilis*.

as a single specimen on lawns, or for streets. Its dense immense crown of elegantly curving pinnate leaves, each often 15 feet long and of a very pleasing green color, and its stately and rapid growth, combine to make this species an ideal avenue tree for central Florida, along with *Sabal Palmetto*, *Washingtonia robusta* and *Phœnix sylvestris*. Farther south *Cocos plumosa* and *Oreodoxa regia* must be added. There are hybrids of this species and *P. sylvestris* and *P. dactylifera*. Seeds from the Riviera and Italy seldom produce plants true to name because the plants evidently are pollinated by the species mentioned. It is necessary to import the seeds

from the Canary Islands, if plants true to name are desired. *P. tenuis* is only a more slender form of it. *P. canariensis* is easily distinguished by its greenish yellow leaf-stalks and spines.—*P. sylvestris* is a very stately and beautiful palm with light bluish green leaves, growing well on high pineland but doing best on rich moist soils. There are hybrids between this species and *P. canariensis*.—The date palm, *P. dactylifera*, is common in many gardens, the product of seeds taken from the commercial dates bought in the shops. Most of the real date palms do not look beautiful. They are rather coarse, but a few of them show a dense crown of deep bluish green leaves. It often produces large bunches of orange-yellow juicy but rather bitter fruit. The mocking-birds are very fond of it. The foregoing three phœnixes are hardy as far north as Jacksonville. The remainder are all more tender.—*P. reclinata* is a most beautiful palm with slender stem and a dense crown of reclining leaves. Great confusion exists concerning this fine palm, as quite a number of the species having more massive stems and much broader and more spiny leaves are labelled with this name. The true *P. reclinata*, as understood in Florida, has soft leaves, and the leaflets are scarcely spiny. Although it suckers, the offsets are not so abundant or so vigorous as in the plant known as *P. spinosa*. It is really a one-stemmed species. The trunk is very slender, scarcely more than 4 or 5 inches in diameter. It grows as well on high dry pineland as in moister and richer soil, but the growth is much more rapid in good soil.—*P. spinosa*, from a horticultural standpoint, is very distinct from the last. The leaves are very vigorous, deep green and each leaflet terminates in a very sharp spine. The foliage is so extremely spiny that it is very difficult to trim the plants. This palm always grows in clumps of five or six or more stems, and it attains a height of 25 to 30 feet. The trunks are rather rough and massive, 9 or 10 inches in diameter, and the leaves are recurving, as in the last.—*P. farinifera*, or the palm grown in Florida under this name, is similar in growth to *P. spinosa*, but the leaves are lighter green with a slight glaucous hue, and the spines on the leaflets are even more formidable. The leaves, particularly at their lower end, are covered with a fine mealy substance.—*P. zeylanica* is one of the most beautiful and distinct of all the phœnixes, with the color of the Colorado blue spruce. If single stems are desired, the suckers should be removed as soon as they appear. This species thrives on high and low land.—*P. leonensis*, by botanists referred to *P. reclinata*, grows in large dense clumps 10 to 12 feet high, scarcely forming trunks. The leaves are deep green, rather soft to the touch and not spiny. Only the petioles are provided, as in all these palms, with formidable spines. It blooms in spring, and fruits abundantly in winter. It grows evidently best on high pineland.—*P. paludosa* forms large clumps, and massive trunks from 1 to 1½ feet in diameter and 15 to 25 feet high; a strong grower but rather coarse in appearance. It grows well on high and low lands.—*P. acaulis* does not form trunks. It is a low, very rigid little palm. The leaves are so spiny that it is difficult to walk among the clumps.—*P. rupicola* (*P. cycadifolia*) is the most elegant and beautiful of all the phœnixes in central Florida. Specimens 6 to 7 feet high look extremely beautiful. The leaves are glossy green and very smooth, suggesting the foliage of some species of *Cycas*. They are elegantly curving to all sides, and as the leaflets are all arranged horizontally in one plane, well-grown specimens form objects of great beauty. It grows well only in rich moist soil and half shade.—*P. Roebelenii* is a dainty little phœnix now represented in many Florida gardens, but it grows well only in rich moist soil and in half-shady spots. It excels all other small palms in grace, elegance, and beauty. (H. Nehrling.)

In California.—The number of species and varieties of phœnix grown in California is a problem so complex

that one dares not attempt a solution. The nursery trade recognizes the following names: *P. canariensis*, *P. cycadifolia*, *P. dactylifera*, *P. leonensis*, *P. Roebelenii*, *P. reclinata*, *P. rupicola*, *P. sylvestris*, and *P. tenuis*. Occasionally other names are met with in private collections, but no others appear in California plant catalogues. All are considered hardy except the dwarf *P. Roebelenii*. Specimens of *P. dactylifera* grow as high as 100 feet. Some specimens grown from seed saved from commercial dates have made

50 feet of trunk in thirty years, while others of the same seeding have made but 8 feet. Either there are numerous hybrids in California or else some species that no one knows. Specimens are known in all shades of green and glaucous-green, all habits of growth, stiff and upright, pendulous and soft, narrow leaves and broad ones, slim-folded and wide-spreading, the latter like an inverted leaf of *Jubæa spectabilis*. No one has attempted to straighten them out. The only species easily recognized everywhere and by everyone is *P. canariensis*, the gem of the genus. This is regarded by one eminent Californian nurseryman as a garden hybrid, but it always produces fertile seeds, and seedlings from it do not vary, which cannot be said of any other phoenix here. Next in popularity comes *P. reclinata*; the others are found only in collections. *P. canariensis* is most easily removed from the ground, and the best time is August and September, the hottest weather, as then they recuperate faster. The only other time to remove is in the early spring, before growth, and then if the weather turns cold it is dangerous. (Ernest Braunton.)

In the North.—Although phoenixes cannot be considered to be as decorative subjects as the howeas and chrysalidocarpos, they are among the hardest of palms. For any unfavorable situation where any palm can be expected to thrive, recommend a phoenix. Outdoors they endure the hottest sunshine without losing a particle of color, whether placed in jars, vases, or beds. As house-plants they are unequaled for resistance to neglect. They also bear the tying and untying and the crowding and wear and tear of public decorative work better than any other palms. The date palm is not quite so graceful as *P. rupicola*; *P. leonensis*, or *P. spinosa*, is slightly stiffer than *P. rupicola*, but very handsome. Other kinds useful to the florist are *P. canariensis*, *P. farinifera*, *P. pumila*, and *P. tenuis*. (This paragraph has

been adapted from an article in Scott's "Florists' Manual" which embodies the experience of Mr. Scott and of the undersigned. (W. H. Taplin.)

INDEX.

(Various other names will be found in horticultural literature, but the following comprise those known to the American trade.)

acaulis, 8.
Andersonii, 1.
canariensis, 10.
cycadifolia, 1, 12.
dactylifera, 12.
excelsa, 12.
farinifera, 4.
Hanceana, 6.
humilis, 6.
Jubæa, 10.
leonensis, 2.
Loureiui, 7.
macrocarpa, 10.
melanocarpa, 2.
paludosa, 3.
pumila, 9.
pusilla, 4, 5.
reclinata, 2.
Roebelenii, 7.
rupicola, 1.
senegalensis, 2.
spinosa, 2.
sylvestris, 11.
tenuis, 10.
zanzibarensis, 2.
zeylanica, 5.

A. Texture of lfts. flaccid.

1. *rupicola*, T. Anders. (*P. Andersonii*, Hort. Calcutta. *P. cycadifolia*, Hort.).

St. 15-20 ft. by 8 in., solitary, slender, naked: lvs. 10 ft., glabrous, bright green: petiole compressed; segms. 1½ ft., 2-ranked, not fascicled, flaccid, bright green: fr. oblong, shining yellow. Sikkim, Himalaya. G.C. II. 8:45. F. 1887, p. 165. I.H. 25:318. F.R. 1:143. A.G. 13:141. A.F. 4:569. Gn.M. 6:288. G.Z. 22, p. 97. R.H. 1912, p. 150. G.W. 1, p. 35.—A form with some of the lfts. white is figured in I.H. 34:3.

AA. Texture of lfts. rigid.

B. Arrangement of lfts. 2-ranked.

c. Form of lfts. lanceolate.

2. *reclinata*, Jacq. (*P. leonensis*, Lodd. *P. senegalensis*, Van Houtte. *P. spinosa*, Schum. & Thom. *P. zanzibarensis*, Hort.). St. to 25 ft. or more: lvs. 2-ranked, bright green, obliquely arcuate-recurved toward the apex; lfts. rigid, approximate, strict, 12 in. long, 1 in. wide, lanceolate, acuminate, pungent, the terminal 9 in. long, slightly

bifid, the lowest spinescent. Trop. and S. Afr. F. 1871, p. 135. A.F. 4:568. A.G. 13:141; 14:410; 16:346. G. 10:409. Gt. 51, p. 623. Gn. 39, p. 140. R.B. 37, p. 334. R.H. 1911, p. 103.—*P. melanocarpa*, Naudin, has black edible frs.; found in garden at Nice. It is "supposed to be a variety of *P. senegalensis*," or by some a hybrid of *P. dactylifera*. R.H. 1894, pp. 493, 496, 497.

cc. Form of lfts. ensiform, with filiform tips.

3. *paludosa*, Roxbg. In groups in the wild state, almost tree-like: trunks 8-25 ft. high, 3-4 in. diam., often reclining, annulate: lvs. 8-10 ft.; lfts. 1-2 ft.,

2920. Phoenix palm.—An unusually straight-trunked specimen of the *P. dactylifera* group.

opposite and alternate, 2-ranked, ensiform, with filiform tips, whitish or mealy beneath; petioles 3-5 ft. long, slender, scurfy, with many long spines; sheath fibrous: fr. black-purple. Along rivers and bays. Trop. Asia. R.H. 1912, p. 423.

BB. Arrangement of lfts. 2-4 or many-ranked.

c. Position of lfts. equidistant.

d. Color of lvs. dark green.

4. *pusilla*, Gaertn. (*P. farinifera*, Roxbg.). Shrubby: caudex at most 4 ft., thickly clothed with old lf.-sheaths: petiole with 1 or 2 pairs of spines; lfts. subopposite, 4-ranked, ensiform, rigid, pungent, dark green: fr. black. Ceylon and S. India.—The caudex is said to have a farinaceous pith, and the foliage to be so spiny that it is impossible to walk through clumps of it.

DD. Color of lvs. light green.

5. *zeylanica*, Hort. (*P. pusilla*, Becc., not Gaertn.). St. 8-20 ft. high, rarely much shorter: lvs. rather short; lfts. very many, subequidistant, 7-10 in. long, bright green, quadrifariouly inserted, linear-lanceolate: fr. obovoid-oblong, red at length violet-blue, $\frac{1}{2}$ in. long. Ceylon.—Fr. edible.

CC. Position of lfts. grouped or fascicled.

d. St. bulbiform: lvs. short.

E. Lfts. scattered, irregularly fascicled.

6. *humilis*, Royle. Sts. short, tufted, bulbiform, rarely elongated: lvs. subglaucous; lfts. scattered, interruptedly fascicled. Very close to *P. acaulis*, but distinguished by the very long-peduncled, fruiting spadix. Hilly districts of India. Var. *Hanceana*, Becc. (*P. Hanceana*, Hort.), from China, is cult.

7. *Roebelénii*, O'Brien. Figs. 2918, 2919. Lvs. 1 ft. or more long; lfts. 5-7 in. long, shining, dark green, soft, curved, subglaucous, often approximate, mostly falcate, not spinous at the tip. Assam to Cochin-China. G.M. 38:80; 53:996. A.G. 15:201. G.C. III. 6:475; 11:731. G.F. 3:273 (adapted in Fig. 2918). A.F. 38:284. G. 22:147; 37:377. Gn. 65, p. 309. Gn.M. 6:289. J.H. III. 64:76. Gt. 61, p. 392.—This dwarf palm, like a date palm but only about 2 ft. high, is variously understood. Beccari, in Webb's, vol. 3 (1910), treats it as a valid species; but Blatter subsequently, in Journ. Bombay Nat. Hist. Soc., makes it a synonym of *P. humilis* var. *Loureirii*, Becc.

EE. Lfts. in nearly opposite fascicles.

8. *acaulis*, Buch. Caudex bulbiform, 8-10 in. diam., densely clothed with sheaths and bases of spiny petioles: lvs. 2-6 ft.; lfts. in subopposite fascicles, many-ranked, $\frac{1}{2}$ -1 $\frac{1}{2}$ ft. long, very rigid, somewhat glaucous, marginal nerve very strong; petiole 1 ft. or more, with many spines: fr. bright red to blue-black. India.

DD. St. erect: lvs. long.

E. Lvs. very slender.

9. *pumila*, Hort. St. slender, graceful, 6-10 ft.: lvs. 10-16 ft. long, recurved, drooping; lfts. 8-12 in. long, 4-ranked. Gt. 20, p. 173 (desc.).

10. *canariensis*, Hort. (*P. tenuis*, Versch. *P. Jübæ*, Webb). Resembling *P. dactylifera*, but more slender and graceful in all its parts: lvs. more numerous. Canary Isls. R.H. 1888:181; 1893, pp. 126, 127; 1912, p. 77. G.C. III. 15:405; 32:81; 54:433. V. 19:51. Gng. 5:215; 12:657. Gn. 57, p. 255. A.F. 22:659. G.W. 8, pp. 26, 28. G. 3:379 (as *P. tenuis*). J.H. III. 68:446. Var. *macrocarpa* is cult. in Florida.

EE. Lvs. more robust.

F. Foliage glabrous.

11. *sylvestris*, Roxbg. St. solitary, stout, 25-40 ft. high, clothed with persistent petiole-bases, the crown very large: lvs. 10-15 ft., glabrous, grayish green;

petiole spiny; lfts. 1-2 ft., fascicled, 6-18 in. long and $\frac{3}{4}$ -1 in. broad, 2-4-ranked, rigid: fr. orange-yellow, the seed rounded at both ends, pale brown. Very close to *P. dactylifera* and perhaps the origin of that plant. India. I.H. 10:351. V. 16:101. F. 1872, p. 29. Gn. 54, p. 117. G.C. III. 10:105. G. 1:248; 9:116. R.H. 1912, p. 149. —A hybrid of *P. sylvestris* and *P. canariensis* secured by E. H. Hart is highly praised.

FF. Foliage glaucous.

12. *dactylifera*, Linn. (*P. cycadifolia*, Hort.).^a DATE PALM. Fig. 2920. St. erect, to 100 ft. and more: lvs. glaucous, arcuate-ascending; lfts. linear-lanceolate, acuminate, 8-16 in. long, strongly complicate, the lower 4-ranked, the upper 2-ranked, irregularly and remotely aggregate: fr. cylindrical-elliptical, 1-2 in. long. Arabia, N. Afr. R.H. 1893, p. 127; 1912, p. 109. G.W. 11, p. 24. Var. *excelsa*, Hort., is cult. in Fla. See Date.

P. andamanensis, Hort. Similar to *P. rupicola*, but more elegant, differing from those in cult. by the regularity of its pinnae and narrowness of the terminal one. Andaman Isls.—*P. dumosa*, Hort. Saul, 1893. Of "dwarf habit." Seems unknown to botanists. —*P. natalensis* and var. *variegata* are offered, but no description is available.—*P. paradensis* is advertised.—*P. Sanderiana*. Presumably intro. within recent years by Sander & Co., St. Albans, England.

WILHELM MILLER.

JARED G. SMITH.

N. TAYLOR.†

PHOLIDOCÁRPUS (Greek, *scale* and *fruit*: the fruit is covered with a scaly coat). *Palmaceæ*. A palm of the oriental tropics. Trunk tall: lvs. orbicular, 4-5 parted; petiole spinous: fr. globose or ovoid with a tessellated pericarp; seed laterally inserted. About 5 species, Malaya, all very imperfectly known. One species, *P. Ihur*, Blume, is sometimes grown in the warm-house and may be suitable for outdoor growth in S. Calif. This has lvs. similar to those of *Borassus flabelifer*, the petioles are armed with stout spines, the spadix loosely branched and the drupe ovoid, about as large as a fair-sized hen's egg, the rind rugose and tessellated and has 3-4 seeds. Malaya.

PHOLIDÔTA (Greek, *scale* and *ear*; the scales of the unopened raceme are said to recall the rattle of a snake). *Orchidaceæ*. Orchids with the habit of *Cœlogyne*, to be grown in a warmhouse, 55° to 65°.

Rhizomes creeping: pseudobulbs consisting of a single internode: fls. small, short-pedicelled, in slender racemes, each with a large bract; sepals and petals short, broad; labellum excavated or sac-like; column very short, winged around the top.—A small genus containing about 20 species, natives of India, S. China, and the Malay Archipelago. For cult., use strong light rich potting material, broken pots, old dry cow-manure, plenty of drainage. Do not allow to become very dry.

imbricata, Lindl. Pseudobulbs oblong sulcate: lvs. oblong-lanceolate, plicate, 6-12 in. long: raceme long-peduncled, 3-8 in. long; fls. small, rather crowded on the raceme, white or yellowish, with a shade of violet. Feb.-May. India. B.R. 1213; 1777. L.B.C. 20:1934.

chinensis, Lindl. A small creeping epiphyte: pseudobulbs caespitose, 1-2-lyd.: lvs. oblong-undulate, acuminate: fls. greenish white, in drooping racemes not more than 2-3 in. long; sepals ovate; petals linear; labellum oblong, recurved.—This plant has long been known from Chinese drawings.

HEINRICH HASSELBRING.

PHORADÉNDRON (Greek, *tree thief*). *Loranthaceæ*. The mistletoe of E. N. Amer. is *P. flavescens*, Nutt. (*Viscum flavescens*, Pursh), Fig. 2921. It is parasitic on deciduous trees as far north as N. J. and S. Ind. and extending southward to Fla. and Texas; also Calif. F.R. 3:590. It makes dense bunches 1-3 ft. across, with thick oval or obovate yellowish green evergreen lvs. The forking twigs are terete, and break easily at the base. The fls. are dioecious, borne in very

short spikes or catkins: berries amber-white, globular, small. It is collected for Christmas greens (see *Greens, Christmas*). The Old World mistletoe is *Viscum*; see also *Loranthus*. (Trelease, *Phoradendron*, 1916.)

The phoradendrons are not cultivated. There are about 100 species of them, all American, largely tropical,

but a few in the western states. The oak mistletoe of California is *P. villosum*, Nutt. A related genus is *Arceuthobium* (or *Razoumofskya*), extending across the continent of North America, but too small, or even minute, to have decorative value.

PHORMIUM

(Greek, *basket*; referring to one use to which this fiber plant is put). *Liliacæ*. NEW ZEALAND FLAX. Very stout rigid perennial herbs prized in subtropical gardening, and in New Zealand used for fiber.

Leaves all radical from a short and stout branched fleshy-rooted rhizome, long-ensiform, equitant, yielding an exceedingly tough fiber: scape tall and leafless, with caducous bracts, short-branched toward top: fls. dull red or yellow, in a terminal panicle, on jointed pedicels; perianth tubular and curved, of 6 segms. connate at base, the 3 inner ones long and spreading at tip; stamens 6, exceeding the segms.; ovary oblong and 3-angled and 3-celled, bearing a slender declinate style: caps. oblong or narrower, loculicidal, bearing many compressed black seeds.—Species 2, in New Zeal. and Norfolk Isl. These plants are popular outdoor subjects in Calif. and climates of like mildness, making very bold lawn clumps. In regions of cold winters, they are known as greenhouse tub-plants or as subjects for planting out in summer in subtropical bedding. They are prop. by seeds or division; if by the latter method, it is well that they be planted outdoors in sandy soil in May and divided in September.

For certain combinations and in places where it can have plenty of moisture, *Phormium tenax* is a valuable plant, having a very distinct and unusual character all its own. The type is easier of cultivation than the variegated kinds. Much better results can be secured by raising the typical form from seeds than by division. Seed sown in February and grown on rapidly will make good plants for bedding purposes the spring of the following year. The seedlings may be either planted out or grown in pots: in the latter case, give a rich compost and plenty of water after the plants have taken hold. With good treatment one may expect at the end of a year and a half a well-furnished specimen 3 to 3½ feet high in a 6-inch pot. If one can afford room in a warmhouse, so much the better. The variegated forms require partial shade and uniform moisture; they do not come true from seed. (J. F. Cowell.)

A. Lvs. to 9 ft. long (in the wild), deep green, glaucous beneath, usually margined with a colored line.

tanax, Forst. NEW ZEALAND FLAX. Fig. 2922. Robust: lvs. attaining 9 ft., 2-5 in. wide, flat above, dark green, margin and keel bright red or brownish:

scape 5-10 or even 15 ft. high, terete and glabrous, reddish purple, bearing numerous fls. which are usually dull red but varying almost to pure yellow; perianth 1-2 in. long: caps. stout, erect or inclined, 2-4 in. long. B.M. 3199. Gn. 26, p. 397; 50, p. 369; 70, p. 99; 73, p. 123. G. 33:553; 36:554. F.E. 18:288. G.L. 27:219. A.F. 13:748. R.H. 1848:5. V. 13:340. Var. *atropurpureum*, Hort., has reddish purple foliage. R.H. 1877, p. 389. Var. *atropurpureum variegatum*, Hort., a "veritable fountain of white, purple and rose-color." Var. *atropurpureum nanum*, Hort., is a dwarf form. Var. *nigro-pictum*, Hort. (*P. purpureum nigro-limbatum*, Hort.). Lvs. deep green, with a narrow margin of blackish purple, which becomes broader and more distinct toward the base, making in mature plants a zigzag line which outlines the 2-ranked habit of the lvs. Var. *variegatum*, Hort., lvs. striped creamy yellow and white. R.H. 1878, p. 86. G.C. III. 29:169. Var. *Veitchianum*, Hort. (var. *Veitchii* and *P. Veitchianum*, Hort.), broad creamy white stripes on a light green ground. A.F. 5:39. The type and varieties all have the red margin. Var. *Powerscourtii*, Hort., differs from the type in narrower and more rigid lvs.; said to be hardier and freer-blooming. G.W. 1907, p. 3.—*P. tenax* is a most useful fiber plant in New Zeal., ranking in economic importance in the native flora only below the main timber trees.

AA. Lvs. to 5 ft. long, pale green, seldom glaucous or margined.

Cookianum, Le Jolis (*P. Colensoi*, Hook. f. *P. Forsterianum*, Col. *P. Hookeri*, Gunn.). A smaller plant and less rigid: lvs. 2-5 ft. long, the apex usually much less split than in *P. tenax*: scape 3-7 ft. high, more slender, green, with smaller panicle: perianth 1-1½ in. long, yellower than the above: caps. long, pendulous, terete and twisted, 4-7 in. long. Var. *variegatum*, Hort., has yellowish white stripes. F.M. 1874:112. G.Z. 19:113. *P. flaccidum*, Hort., is presumably a form of this species.

WILHELM MILLER.

L. H. B.†

2922. *Phormium tenax*.

PHOTÍNIA (Greek, *photeinos*, shining; alluding to the shining foliage). Including *Heterómeles* and *Pourthiæa*. *Rosacæ*, tribe *Poméæ*. Ornamental woody plants, grown for their attractive flowers and fruits and the evergreen species also for their handsome foliage.

Deciduous or evergreen shrubs or trees: lvs. alternate, short-petioled, stipulate, usually serrate: fls. in corymbs or short panicles; petals 5, orbicular; stamens 10-20; styles 2, rarely 3 or 4, connate at the base: fr. a small, 1-4-seeded pome with persistent calyx and with the top of the fr. rounded and hollow.—About 30 species, nearly all in E. and S. Asia, only 2 in Calif. and Mex.

Closely allied to the *Aria* group of *Sorbus*, which differs chiefly in the top of the fr. being solid and pointed.

The photinias in cultivation are shrubs, rarely trees, with rather large evergreen or smaller deciduous leaves turning scarlet or deep red in fall and with white flowers in many-flowered or sometimes few-flowered corymbs followed by very attractive red or scarlet fruits. The evergreen species are tender in New England, and bear only a few degrees of frost; but the deciduous *P. villosa* is hardy as far north as Massachusetts, and is very conspicuous in fall by the scarlet coloring of the foliage and afterward by the numerous scarlet fruits, which retain their bright color until midwinter and are not eaten by birds. Of the evergreen species, *P. arbutifolia*, which is very similar to *P. serrulata* and also to *P. glabra*, is the best known; it is a very striking object in winter, with its large clusters of bright red fruit ripening in December and contrasting well with the glossy dark green foliage. The photinias are not very particular as to soil, but thrive best in a rather light sandy loam, and the deciduous ones prefer sunny positions. Propagation is by seeds or by cuttings of half-ripened wood under glass and by layers; also by grafting on hawthorn or quince.

A. *Lvs. deciduous: fls. in corymbs or umbels. (Pourthiæa.)*

villôsa, DC. (*P. variabilis*, Hemsl. *Pourthiæa villosa*, Deene. *Sorbus terminalis*, Hort.). Upright shrub, to 15 ft., with slender spreading or upright branches, or small tree: lvs. short-petioled, broadly obovate to oblong, cuneate, acuminate, sharply serrate, dark green and glabrous above, more or less pubescent beneath when young, $1\frac{1}{2}$ -3 in. long: fls. white, in $1\frac{1}{2}$ -2-in.-broad, glabrous or villous corymbs terminal on short lateral branchlets: peduncles warty: fr. about $\frac{1}{2}$ in. long, bright scarlet. June; fr. in Oct. Japan, China. G.F. 1:67. S.I.F. 1:49.—A very variable species. Var. *lævis*, Dipp. (*P. lævis*, DC. *Pourthiæa arguta*, Hort.), Fig. 2923, has narrower lvs., only sparingly pubescent when young and soon glabrous, glabrous infl. and somewhat larger fr. G.F. 4:377 (adapted in Fig. 2923). Var. *sinica*, Rehd. & Wilson. Shrub or tree, to 30 ft.: lvs. thinner, elliptic or elliptic-oblong, sparingly pubescent at first, soon glabrous: infl. an umbel-like 5-8-fld. raceme, rarely corymbose, to 15-fld., loosely villous. Cent. China.

subumbellâta, Rehd. & Wilson. Slender-branched shrub, 3-10 ft.: lvs. very short-stalked, elliptic-ovate to rhombic-ovate, acuminate, broadly cuneate or rounded at the base, sharply serrulate, glabrous, bright green above, pale or glaucescent beneath, $1\frac{1}{2}$ -2 $\frac{1}{2}$ in. long: fls. in umbel-like 2-9-fld. glabrous racemes subtended by 2-3 crowded lvs.; pedicels slender, $\frac{1}{2}$ -1 in. long: fr. ovoid, nearly $\frac{1}{2}$ in. long, scarlet. May, June; fr. in Oct. Cent. China.

AA. *Lvs. evergreen: fls. in broad panicles.*

B. *Stamens 20. (Euphotinia.)*

C. *Petioles longer than $\frac{1}{2}$ in.: lvs. usually 4-6 in. long.*

serrulâta, Lindl. (*P. glabra* var. *chinensis*, Maxim. *Cratægus glabra*, Sims, not Thunb.). Shrub, to 20 ft., quite glabrous: winter buds about $\frac{1}{2}$ in. across, ovoid: lvs. with about 1-in.-long petioles, oblong, usually rounded at the base, acuminate, serrulate, dark green and shining above, yellowish green beneath, 5-7 in. long; petioles about 1 in. long: panicles 4-6 in. broad, with thick sh and slightly angular branches; fls. $\frac{1}{2}$ in. across: fr. globose, $\frac{1}{4}$ in. across, red. May-July. China. B.M. 2105. L.B.C. 3:248. L.D. 8:554 (all as *Cratægus glabra*). G.W. 15, p. 247.—Stands fairly well in Washington, D. C.

Davidsoniæ, Rehd. & Wilson. Tree, to 45 ft.: winter buds minute, acutish: branchlets appressed-pubescent while young: lvs. oblong-lanceolate or oblong, acuminate or acute cuneate at the base, serrulate, lustrous and bright green above, paler beneath and pubescent on

the veins at first, soon glabrous, 3-5 in. long; petioles about $\frac{3}{4}$ in. long: panicles 4-5 in. broad with slender terete branches, sparingly pubescent; fls. nearly $\frac{1}{2}$ in. broad: fr. subglobose, orange-red, $\frac{1}{2}$ in. across or slightly more. May: fr. in Oct. Cent. China.—One of the handsomest evergreen trees of Cent. China; recently intro.; probably as hardy as the preceding species.

CC. *Petioles shorter than $\frac{1}{2}$ in.: lvs. usually 2-3 in. long.*

glâbra, Maxim. (*Cratægus glabra*, Thunb. *Sorbus glabra*, Zabel). Shrub, to 8 ft.: lvs. on nearly $\frac{1}{2}$ in.-long petioles, elliptic or obovate to oblong-obovate, cuneate at the base, acuminate, serrulate, 2-3 $\frac{1}{2}$ in. long: panicles 2-4 in. across; fls. $\frac{1}{2}$ in. across: fr. subglobose, red. May-July. China, Japan. S.I.F. 1:47.

BB. *Stamens 10. (Heteromeles.)*

arbutifolia, Lindl. (*Heteromeles arbutifolia*, Roem. H. *salicifolia*, Abrams. *Cratægus arbutifolia*, Ait., not Lam.). TOYON. TOLLON. Shrub or small tree, to 20 ft.:

2923. *Photinia villosa* var. *lævis*. ($\times \frac{1}{2}$)

young branches and infl. usually tomentulose: lvs. oblong to oblong-lanceolate, acute at both ends, sharply serrate, shining above, 2-4 in. long: fls. white, in 2-5-in. broad panicles; stamens 10: fr. bright red, $\frac{1}{2}$ in. across. June, July; fr. in Nov.-Feb. Calif. S.S. 3:193. B.R. 491.—Called Christmas berry in Calif., where the frs. are much used for Christmas decoration.

P. amphidôza, Rehd. & Wilson (*Stranvæsia amphidôza*, Schneid.). Shrub, to 10 ft.: lvs. deciduous, elliptic to oblong, serrate, loosely tomentose at first, soon glabrous, 2-3 $\frac{1}{2}$ in. long: fls. 3-6; calyx densely tomentose: fr. subglobose, scarlet, $\frac{1}{2}$ in. across. Cent. China.—*P. arguta*, Wall. (*Pourthiæa arguta*, Deene.). Closely allied to *P. villosa*: lvs. longer and narrower, firmer, densely white-tomentose beneath when young: corymbs larger. Himalayas.—*P. Beauverdiâna*, Schneid. Shrub or small tree, to 20 ft.: lvs. deciduous, oblong or obovate-oblong, densely serrulate, glabrous, 2 $\frac{1}{2}$ -4 in. long: corymbs 2 in. across: fr. subglobose, scarlet, $\frac{1}{2}$ in. across. Cent. China. Var. *notabilis*, Rehd. & Wilson (*P. notabilis*, Schneid.). Lvs. elliptic to obovate-oblong, 3-5 in. long: corymbs loose, 3-4 in. across: fr. ovoid, $\frac{1}{2}$ in. long. Cent. China.—*P. elliptica*, Nichols, is *Eriobotrya elliptica*, Lindl., a Himalayan species not in cult. in this country.—*P. japonica*, Nichols.—*Eriobotrya japonica*.—*P. parvifolia*, Schneid. Shrub, to 6 ft.: lvs. elliptic, long-acuminate, serrulate, nearly glabrous, $1\frac{1}{2}$ -2 in. long: fls. 2-3 on filiform stalks 1-2 in. long: fr. ovoid, scarlet, $\frac{1}{2}$ in. long.

ALFRED REHDER.

PHOTOGRAPHY, HORTICULTURAL. As a means of description and of record, photography is of great importance to horticulture in all its branches. A reference to newspapers, magazines, and to trade catalogues of the day shows an almost universal use of the "half-tone" engraving process; and these engravings are merely photographs transferred to a copper plate, and by means of minute chemically-etched dots given a printing surface for the typographic press. Many other illustrations—notably many in this *Cyclopedia*—are adapted from or drawn directly from photographs, being then engraved by another photographic etching process on hard zinc. Other processes are now employed, as yet principally for newspaper use, which transfer much of the beauty of the photograph through the photogravure method. As will be noted farther on in this article, there is also actual photography in colors now available. To a limited and decreasing extent, photographs are also printed on the prepared surface of boxwood blocks, and used in lieu of a drawing as a sketch for the wood-engraver.

Every experiment station and agricultural college finds in photography an indispensable adjunct both to its records and to its descriptive work. For the botanist, photography provides both an uniquely accurate means of recording plant details, and of portraying the appearance of the growing plant in its habitat. A photographic herbarium is an excellent supplement to the usual dried specimens of the botanist. Some of the larger nursery and seed establishments are also coming to maintain photographic equipments, in order that they may readily preserve views of the varieties which it is desired to advertise.

In horticultural journalism, photography is of prime importance. In advanced collegiate institutions and at the meetings of various progressive horticultural societies and institutes, the presentation of photographs by means of the stereopticon is found to be of enormous advantage, and the teaching or entertainment is made more efficient through this means. Recently, the motion-picture camera, through the use of which in connection with suitable projecting apparatus, operations in the field are presented a close simulation of actual life, has been availed of to advantage. For example, a "film" of considerable length records all the operations attendant upon the planting, cultivation and marketing or preserving of asparagus in the large areas devoted in California to the culture of that vegetable. A drama has been "staged" at a great gladiolus farm, and one rather grotesque film ingeniously recorded the seemingly accelerated growth of an unfolding lily and of a rose in the process of opening. Therefore, all branches of horticultural activity are concerned with photography, and the progressive instructor dealing with horticultural problems in an educational institution, or handling the government's money in the experiment-station work, must be able to practise at least some one photographic method with a fair degree of proficiency, if he is to accomplish the best results.

As horticultural photography differs essentially from the line of work in which the ordinary portrait photographer is engaged, some special skill and certain items of equipment are desirable for the tradesman, or experimenter, or teacher who wants to make his illustrations effective. Those who deal with many photographs from many "artists," come to know the thoroughly inadequate work of the ordinary professional, who is fitted both as to equipment and skill only for the picturing of the human face and form. Not once in twenty times does satisfactory and efficient horticultural photographic work come from the professional; and, therefore, the horticultural instructor or tradesman is best served by taking up photography in an independent manner, if he gives the subject adequate attention.

Apparatus.

For views outdoors of trees, plants, and the like, any view camera of the regulation or of the "folding" type will answer, although, as it is often desirable to obtain relatively large details of fruits or flowers or plants *in situ*, a bellows of more than the usual focal capacity or length is preferred. The modern "long-focus" cameras are suitable, and the size most used by horticulturists is that taking a plate 5 by 7 inches in dimensions. For such size a rectilinear lens with a focal length of 7 or 8 inches is advisable; and if one of the two lenses forming the combination is available as an objective of about double the focal length of the combination, and the camera is provided with a bellows which draws out several inches beyond the focal length of this single lens, much facility in operation is provided. Any of the modern high-class view lenses are suitable, and those of the anastigmatic type, which are not only rectilinear but also render views in a flat and correct perspective, are preferable. It need not be assumed, however, that the very highest-grade lens is essential, for in the hands of a thoughtful and reasonably skillful operator, an ordinary rectilinear lens, costing, for the size mentioned, but \$15 or \$20, will often do satisfactory work. Whatever lens is used, it should be fitted into a quick-working shutter, as outdoor exposures, with modern rapid plates, must be made in small fractions of a second. The shutter, it may be explained to the unacquainted reader, is merely a convenient device for opening and closing the lens to the light for the interval of time desired by the photographer.

As there is frequent misconception of the work done by a lens, it may not be amiss to suggest to the inquiring horticultural photographer an investigation on his own account. The *Photo-Miniature* No. 140, "Lens Facts You Should Know," is a brief, clear, and concise statement of the principles, properties, and construction of lenses, which may be consulted to advantage. The focal length of any lens, in connection with the size of the plate upon which it is to be used, determines the angle and amount of view included. The human eye is a lens of about 16 inches focal length, and to have a photograph render perspective as seen by the average eye, an objective of the same focal length is required. Thus, on a 5 by 7 plate, a lens of 8 inches focal length will include twice as much in the view, and show it in half the size as seen by the eye. This forced perspective is sometimes desirable and sometimes unpleasant. If the 8-inch lens is composed of two elements on what is known as the symmetrical plan, the rear element may usually be used alone (by screwing out the front lens), and it will have approximately double the focus of the combination. This will give about the perspective seen by the human eye, and will need to be used in connection with a bellows of at least the same length or "draw" as the focal length of the lens. Some of the high-grade lenses are now made on what is termed the "convertible" plan, each of the two elements being of a different focal length. Thus a certain lens which as a whole is of $7\frac{1}{2}$ inches focus, includes one element of 12 inches focus and one element of 18 inches focus. Either of these single lenses, or the combination, may be used separately, so that from a given position three views, including proportions differing as 5, 8, and 12, may be made.

To photograph an object in natural size, the double lens is preferable. If the lens is of 8 inches focus, it will give natural size when placed equidistant between the object and the ground-glass focusing-screen of the camera, at double its focal length. Thus the bellows would need to be drawn out so as to have 16 inches between the ground-glass and the lens, while the object to be photographed should be maintained in position 16 inches from the lens.

A tripod, capable of adjustment as to height, and of

sufficient rigidity to sustain the camera in a moderately high wind, is easily obtained. The cheaper forms are fairly efficient, but the photographer who has much traveling to do finds it preferable to obtain one of the more expensive and carefully fitted types, which fold into a smaller compass.

For indoor work, including the making of photographs of fruits, flowers, or plants in large detail, a special form of camera-stand is very desirable. One arranged so that the camera may be maintained in an inclined or nearly vertical plane, while the object to be photographed rests on a plate-glass exposing-stand in front of the lens, gives great facility and ease of operation, and does away with many difficulties of illumination. A few experiment stations possess devices of this kind. A form which has been found exceedingly satisfactory in practice is described in an out-of-print number of *The Photo-Miniature*, "Photographing Flowers and Trees," and is here reprinted by permission in Figs. 2924 and 2925, showing the camera-stand both as arranged for horizontal and for vertical work.

2924. Adjustable camera-stand, horizontal position.

In operation with this device the flower, fruit, or plant to be photographed is laid upon or placed in front of the plate-glass stand, and the camera, fastened by its tripod screw upon a movable bed, is adjusted as a whole, or through its bellows, until the desired size and focus are secured. The background may be varied as desired by cardboards or cloths placed out of focus in relation to the plate-glass stand. The camera-stand is mounted on casters, so that it may be readily moved about to secure the most favorable lighting. Objects which can best be handled on a horizontal plane may be disposed somewhat as shown in Fig. 2924. For work of this sort a north side-light is found vastly preferable to the conventional sky-light. A greater mistake in the equipment of a studio for horticultural work could not be made than to provide the sky-light deemed essential by old-fashioned professional photographers, although now happily abandoned by the more progressive workers for a "single-slant" light, which gives far better results. There should be provided in the workroom of the horticultural photographer several good reflecting surfaces, so that the side of the object opposite the main source of light may be properly illuminated.

All the apparatus above mentioned is applicable to color-photography by the Lumière method, as herein-after sketched; but motion-picture photography requires apparatus peculiar to itself.

Under certain conditions, the use of the "flashlight" methods may be advantageous in horticultural photography; as, when an outdoor object must be obtained at night, or indoors where a flower may wilt under prolonged exposure. Flashlight processes depend upon the explosion or the rapid combustion of certain metals—as magnesium—which, either alone or in combination with oxygen-giving chemicals, produce a light of great brightness and high actinic power for an instant. Further information upon flashlight may be found in

2925. Adjustable camera-stand, vertical position.

The Photo-Miniature No. 135, "Flashlight Photography."

The horticultural photographer also requires an outfit for developing and printing; but as this may be conventional, it is not deemed necessary to discuss it here.

Plates and color-values.

As practically all horticultural photography has to do with the tints of growing things, the well-known color inaccuracy of the ordinary dry-plate is a serious disadvantage. The ordinary plate responds most actively to the rays at the blue end of the spectrum, and is very sluggish in taking an impression from green, yellow and red, the latter color, indeed, being rendered practically the same as black. Yellow, which in actual color-value is on a par with light blue, and sometimes to the eye seemingly more intense than white, is rendered by the ordinary plate as a dark color, as all operators who have photographed yellow roses, yellow apples, yellow plums, and the like, will have observed. Fortunately, there are available photographic plates, known as isochromatic or orthochromatic plates, which, to a certain extent, correct these difficulties;

and the skilful operator may, by the use of the proper plate and in some cases a suitable ray-filter, give approximately correct values to all the colors of the spectrum. For all ordinary horticultural uses, when blue and yellow are not found in the same subject, the commercial orthochromatic or isochromatic plates of the most rapid speed are satisfactory. These give to yellow its proper value, at the same time improving the rendering of the green foliage and slightly increasing the truth of representation in pink, lavender, and the lighter red shades.

It is very much better, then, for the photographer who has to do with horticultural work to confine himself exclusively to these plates for all his work. If he has a subject including blue flowers, the especial activity of the blue rays, which otherwise would render the photographic impression as intense as if the object was white, can be restrained by a suitable ray-filter, which is applied in front of the lens. This ray-filter is either a glass cell filled with a 1 per cent solution of potassium bichromate, or a piece of plane optical glass covered with a suitably stained collodion film sealed with another optical glass and provided with a convenient mounting for slipping on the lens. (Such ray-filters may be commercially obtained at small cost, but ought to be known to be adequate for the particular plate to be used.) With this ray-filter and the plate before alluded to, the yellow is slightly over-valued, but the blue is given its proper relation. The beauty of outdoor photographs is vastly increased by the use of the plate and ray-filter mentioned, because a proper color-value is given to the sky, and the cloud-forms are preserved in all their attractiveness. If the subject is a heavily loaded peach tree, for example, the accentuation of the yellow, brought about by the use of the ray-filter, will give a needed slight exaggeration of color-value to the fruit, which, under treatment by an ordinary plate, will be almost indistinguishable from the mass of foliage. With the usual ray-filter the exposure required is practically trebled. In this *Cyclopedia*, advantage has been taken of orthochromatic plates in photographing many of the subjects. The carnations, Plate XXII, Vol. II, show a variety of shades properly rendered by the means indicated. The grapefruit, Plate L, Vol. III, is an example of the use of the ray-filter also to obtain the full color-value of the fruit.

A difficulty known in photographic practice as halation must also be counteracted if the fine detail of subjects involving much light is to be preserved. Halation is caused by the reflection of brilliantly lighted objects from the back of the glass plate carrying the sensitive emulsion. Light possesses enormous velocity, and there is an almost inconceivably rapid play back and forth between the two surfaces of the glass plate, which is covered only on its face by the sensitive photographic emulsion. This results in a thickening of all the finer lines which should be rendered in the positive as white. It may be counteracted by "backing" the plate with a composition which will absorb all the rays of light that pass through the emulsion on the face; but in current practice a slightly less adequate and much more convenient prevention of halation is secured in the use of what are known as "double-coated" plates. A "slow" emulsion, first coated on the plate, is covered by a "fast" emulsion, with the effect of absorbing into the under-coating, in exposure, the overplus of light. These plates, incidentally, also give greater latitude of exposure, and their use is recommended, with the provision that both coatings should by all means be orthochromatic.

Even with the aid of the isochromatic plate and the ray-filter, the photography of shades of red is difficult, because of the lack of actinic or chemical quality in the red rays of the spectrum. In practice it is found necessary to give a very much prolonged exposure to objects containing red, and then to restrain the over-exposure

upon development by means of a suitably compounded developing solution.

Lantern-slides.

A lantern-slide is a positive on glass, and therefore is made from a negative. It is made preferably on a special plate, much slower than the regular photographic dry-plate, because coated with silver chloride rather than a silver bromide emulsion. The slide is usually faced with a paper mask, so as to include only the desired portions of the picture, and protected by a cover glass. Negatives of any size may be used if a suitable arrangement is provided for reduction. This can readily be arranged by an adaptation of the camera-stand illustrated in Fig. 2924. A pair of light bars is added, running from the top of the plate-glass frame to a support at the other end of the stand, and a piece of heavy muslin or light canvas thrown over this serves to exclude the excess of light. A ground-glass frame is added back of the plate-glass, which latter is removed to give place to a turn-table arrangement, made to take and hold negatives of various sizes. In practice, the ground-glass end is turned toward the strong light, the negative to be used is adjusted in the turn-table, and the image focused in the camera as usual. The 5 by 7 size largely used by horticulturists is in just the right proportion for the ordinary lantern-plate of American practice, which is $3\frac{1}{4}$ by 4 inches. Slides may also be made by contact, if the negative to be used is of suitable size. The familiar 4 by 5, $3\frac{1}{2}$ by $3\frac{1}{2}$, and $3\frac{1}{4}$ by $4\frac{1}{4}$ hand-camera films are often so used, being placed in contact with a lantern-plate in an ordinary printing-frame, and given a short exposure to an artificial light. Such slides are seldom of good quality.

If it is required to make lantern-slides from diagrams, engravings or any positive material, a negative is first prepared, for making which the vertical position of the camera-stand (Fig. 2925) is very convenient. For many diagrams and for most "reading slides," there is much advantage in making the slide directly without the intervention of a negative, with the result that the letters or lines are shown as clear glass. The audience sees only the message or object, the background being dark; and the excessive light reflection, tending to tire the eyes, is avoided.

In making lantern-slides, it is important to learn the proper exposure, for errors in exposure cannot be corrected in development to any great extent. The careful worker will expose several plates upon the same subject, give all the same development, and act upon the experience thus gained. The standard all too often accepted by those who use lantern-slides is unfortunately low. Manufacturers competing wholly on the lowest price basis have accustomed even thoughtful persons to think their productions adequate, instead of which they are unfortunate, because they believe rather than reproduce the object to be shown.

Lanterns for projecting these slides are now simple, convenient, and cheap. One form, available wherever access may be had to an electric-light socket, can be carried in a small case and set up for use in less than ten minutes. It perfectly projects an image up to 6 or 8 feet in diameter, and is without complications. Built of aluminum, it is solid and durable, and its cost is but one-fourth that of former apparatus.

Colored lantern-slides.

The value of a good lantern-slide is increased more than tenfold if the slide is so colored as to show upon the screen the object or scene in natural hues. It is not difficult, with suitable knowledge and sufficient practice, so to tint the lantern-slide as to accomplish this object, and there are a number of notably successful colorists whose work has given information and pleasure to thousands.

In practice, if a lantern-slide is to be colored, it is

usually made slightly less dense or "contrasty" than if it is to be shown without color. A photographer's retouching stand, which excludes light from the eyes of the worker and reflects light through the ground-glass and also through the slide to be colored, is needed. Coloring is effected by means of the use of dyes and stains of various characters, usually obtainable in the market. The color is applied by the use of brushes of varying sizes. The capable worker constantly compares the result of his efforts, either with standard slides of high quality or through projection upon a screen by means of a small lantern.

One reason why colored lantern-slides are so much more effective than those uncolored is in their exclusion of excessive light, which tends to dazzle and weary the eyes of the spectator, as previously suggested. Thus, a sky is blue and agreeable rather than white and dazzling.

Transparent colors must be exclusively employed, inasmuch as the effect to be obtained on the screen through projection is wholly that of transmitted light, and not by reflection.

The use of lantern-slides in general and of colored slides in particular for educational purposes has been greatly fostered by the action of several states in establishing departments of visual instruction, in which are grouped collections of carefully made lantern-slides upon various subjects, frequently available to residents of the particular states without other charge than transportation and a responsibility for damage. Pennsylvania, New York, Washington, Illinois, and Kansas are known to maintain such departments.

Motion-picture photography.

Reference has been made to the recent development of motion-picture photography. Motion-pictures are at present being viewed by many millions of persons daily in the various centers of population in the United States, but as yet little organized effort has been put forth for preparing motion-pictures primarily for educational purposes. Through the federal government, and in the Department of the Interior, the national parks are brought into notice by means of motion-picture films; and it is probable that a motion-picture outfit, both for the making of the exposures and for the proper display of the result, will shortly become an essential factor in connection with any modern educational institution. Particularly in reference to horticulture is it probable that the motion-picture will show to advantage orchard and planting operations and the growing of great crops (as before mentioned in connection with asparagus, for example), and similarly will teach quickly and entertainingly many things now less adequately presented.

Photography in natural colors.

Many investigators have worked on this problem, but without what might be called reasonable and available success, until, in 1907, the Lumière brothers, acute opticians and plate manufacturers at Lyons, France, painstakingly developed what is known as the autochrome process. This process uses the known but unappreciated fact that color is not an inherent property of matter, but a sensation of the eye relating wholly to the character of light reflected from any object. Exceedingly minute particles of nearly transparent starch, colored to three primary hues, are intermingled and spread in a single layer over the surface of a glass plate, and upon this layer there is coated a sensitive and so-called panchromatic photographic emulsion. These minute starch particles, averaging about 5,000,000 to the square inch, serve when the prepared plate is exposed glass side to the object (contrary to the usual practice) to separate or screen out the reflections from the object transmitting certain intensities relating to

the colors then expressed in that particular light. Thus, from a red rose with green leaves, light is reflected through these dots to the effect that the underlying photographic emulsion is suitably affected for the purpose in mind. After exposure there occurs a process of development and re-development which removes most of the photographic emulsion save such as marks out the delineation of the object as depicted by the lens, and as will serve to obscure the colors not wanted.

Under favorable conditions, the effect is an actual photograph in color upon a glass plate or transparency, which must be viewed as such by transmitted light suitably reflected from a white cloud or a white surface. If the light used in reflection has a differing spectrum from that used in the making of the view, the colors will not be seen as they were when the photograph was taken.

As yet no means have been devised for adequately duplicating these transparencies on glass, which, therefore, while very beautiful when properly made and viewed, serve rather as color memoranda or records than for the reproductive purpose conceived of an ordinary photograph.

In this book use has been made of the autochrome for obtaining the color records upon which the various color plates have been produced. For example, Plate VIII, Vol. I, showing the York Imperial apple, is a successful reproduction of an autochrome, as also is Plate XX, showing hardy bulbs in full color, and Plate XXV, celery, showing current commercial practice in exact color.

These autochromes are relatively expensive to make, but require only a special ray-filter in addition to the ordinary camera equipment. With autochrome plates the careful worker is able to obtain many important and delightful records.

Inasmuch as the autochrome is viewed with success only by transmitted light, it early occurred to those working in this method to propose the autochrome as a means of obtaining a perfectly colored lantern-slide. Several collections have been made which show in an exceedingly beautiful manner great scenery, portraits, and the like, but the disadvantages encountered are to the effect that inasmuch as the autochrome is much less transparent than the average lantern-slide, it cannot be shown with success in connection either with an uncolored or a colored lantern-slide. If autochrome lantern-slides are grouped together and shown in a relatively small image with a very intense light (preferably that of the electric arc only), the result is excellent.

Other methods said to accomplish color photography spring up from time to time. So far, however, not one of them has been found to be of a permanently valuable and desirable character, or in any sense equal to the autochrome, which in itself is rather inadequate.

The use of photography in relation to horticultural education and merchandising is merely in its infancy. It is probable that greatly improved methods of reproduction will permit of the more extensive and more effective use of photographs, and it seems certain that the moving-picture will assume a much greater importance in educational, philanthropic, and commercial practice. Acquaintance with photography is, therefore, likely to prove of increasing value to the horticulturist.

J. HORACE MCFARLAND.

PHOTOSYNTHESIS. Green plants exposed to sunlight at a growing temperature are able to manufacture organic food substances, that is, carbohydrates. The term photosynthesis, derived from Greek words signifying "light" and "putting together," is applied to this process of food manufacture. Green plants manufacture not only their own food carbohydrates but also are the sources of practically all of the organic matter which may eventually furnish food for both plants and

animals. It may be said, therefore, that life today is dependent upon the green leaf. The first carbon-containing compound made is a relatively simple substance, but the first recognizable material is sugar. The crude materials out of which organic substance is made in the cells of the green tissues are CO_2 (carbon dioxide) and water. The leaf green, chlorophyl, and the protoplasm of the cell may be regarded as the important mechanism, while the source of energy for the chemical change induced is radiant energy, light. Air ordinarily contains about .03 per cent of CO_2 , yet the ordinary green plant obtains all of its carbon for the making of organic matter from this extremely small quantity in the atmosphere. The chlorophyl is important inasmuch as it absorbs the radiant energy which is directly or indirectly responsible for the process. Chlorophyl is distributed within the cells in definite granules, or small bodies, protoplasmic in nature, commonly ovoidal in form. The light absorbed is largely from the red or red-orange portion of the spectrum. It is possible that the energy so derived is first transformed into electrical energy, yet little is known upon this point. It is certain, however, that green plants are unable to utilize energy derived, for example, from the absorption of heat. The process may be briefly pictured in the following manner: The cell-sap absorbs the CO_2 which diffuses into the tissues from the air. By means of the energy absorbed by the chlorophyl bodies, within the cells, the CO_2 is supposed to be reduced to CO (carbon monoxide), and the same means resolves the water into its constituents. The products of these molecular changes form new substances, perhaps formaldehyde (CH_2O) and oxygen (O_2). The formation of formaldehyde is still somewhat uncertain; but in any case sugar is soon recognized. In all probability the formaldehyde molecules are immediately condensed to sugar ($\text{C}_6\text{H}_{12}\text{O}_6$). It will be noted that the surplus oxygen is in reality a by-product and during active photosynthesis it is produced in such quantity as to be actively eliminated from the plant by diffusion. The usual test for photosynthesis is carried out by counting the bubbles given off from the cut stem of a water plant exposed to sunlight in a well-aerated vessel of spring-water. The content of oxygen in these bubbles is greater than that of normal air, and the rate of bubble-production is a fair estimate of the rate of photo-synthesis.

As a rule the sugar formed in the leaf does not accumulate to any large extent, but is transformed into starch. Some of the sugar, however, may be immediately diffused to other cells or "transported," supplying the needs of this substance in growth. The starch which is deposited is in the form of insoluble granules, and the formation of these bodies on exposure of the green leaf to sunlight is so rapid as to make it possible in some cases to use starch formation as an index to rate of photosynthesis. During the night, when no photosynthesis occurs, the transformation and removal of the starch usually goes on rapidly, so that within an interval of twelve hours most of that formed during the day seems to have disappeared from the leaf. It is, in fact, changed to sugar prior to transportation but may be removed to other organs of the plant, as, for example, to fleshy roots or tubers, where it may again be converted into starch, accumulating at times to a very considerable extent.

Photosynthesis is most rapid under those conditions of temperature which are favorable for growth. Under strong light and favorable temperature, however, a slight increase in the amount of CO_2 gives a higher rate of starch-production. The presence in the leaf or stem of other color bodies, such as browns and reds, is no indication that chlorophyl is absent. As a matter of fact, chlorophyl is generally present in such cases, but may be veiled by the more prominent color. In showy flowers, however, chlorophyl seldom occurs. Pho-

tosynthesis is inhibited by any condition affecting the general health of the plant, and it is low during cold and dark weather. The larger number of plants are most active in the brightest sunlight, but certain shade-loving species are injured by such exposures, and are adjusted to conditions of half-shade, such as obtain in the shade of trees or bushes.

B. M. DUGGAR.

PHRAGMITES (Greek, *growing in hedges*, apparently from its hedge-like growth along ditches). *Gramineæ*. Large grasses, useful for planting in wet places.

Tall stout perennials with long running rootstocks, strong culms and terminal panicles with the aspect of *Arundo*: spikelets 3-7-fld. Differs from *Arundo* chiefly in having glabrous sharp-pointed not bifid lemmas, the long hairs confined to the rachilla-joints, and in that the lowest floret is staminate.—Species 3, 1 in Trop. Asia, 1 in S. Amer. and 1, our species, cosmopolitan.

communis, Trin. (*P. vulgaris*, BSP). COMMON REED. Culm usually 8-10 ft. high: lvs. 1-2 in. wide. Marshes and along edges of ponds. Dept. Agric., Div. Agrost., Bull. No. 20:126. Gn. 31, p. 33.—The ornamental feathery drooping panicles appear in late summer or autumn. A form with variegated lvs. is sold under the name *P. communis variegata*, or spire-reed.

A. S. HITCHCOCK.

PHRAGMOPEDILUM (Greek, *phragmos*, a fence, alluding to the divisions of the ovary). *Orchidaceæ*. Terrestrial or epiphytic glasshouse orchids, formerly included (with *Paphiopedilum*) in *Cypripedium*.

Flowers numerous, deciduous, in a raceme or panicle; sepals 3, the lateral united into one organ located beneath the lip, the other back of the column known as

2926. *Phragmopedilum Schlimii*. ($\times \frac{1}{2}$)

the dorsal sepal; petals 3, the lateral similar, the other widely different, forming a pouch or sac known as the lip, the margins all around the orifice reflexed or turned in; column short; stamens 2; ovary cylindric, 3-celled, the walls thick, the ovules borne on placenta on the divisions.—About 11 species (Pfitzer, in Engler's *Pflanzenreich*, hft. 12 [iv. 50], 1903), Trop. Amer. from Panama south. The species here considered were contained in

Selenipedium in *Cyclo. Amer. Hort.* The genus *Selenipedium* is still retained by botanists, however, with which *Phragmopedilum* agrees in the 3-celled ovary but from which it differs in habit, conduplicate coriaceous strap-shaped lvs., the fl. being articulated above the

(Hybrid; see supplementary list,
page 2604)

ovary and deciduous, and the seeds being fusiform. The orthography of the name is somewhat confused. The word was originally spelled *Phragmopedilum* as a section of *Paphiopedilum*, and this form is adopted by Pfitzer and by Index Kewensis.

Rolfe, the English authority, at first wrote it *Phragmipedium* and more recently *Phragmipedium*. (See discussion by him in *Orchid Review*, 9, 174, 175.)

All *phragmopedilums* enjoy plenty of heat and moisture in the growing season, March to November (65° to 90°). Give good drainage. Use chopped sphagnum with broken clinkers from the furnace, and the addition of a little leaf-mold, raising the material as high above the rim of the pot as possible. This material is especially to be recommended for the young and divided plants. Give slight shade, and grow on raised benches near the glass. Water sparingly until growth begins. The four species, *P. Dominicanum*, *P. Sedenii*, *P. Schlímii* and *P. Sargentianum*, should not be overpotted. Fill pots three-fourths full of drainage, then place a thin layer of coarse fern-root, which will fill pot to level of the rim. Place the plant on top of this and then fill 2½ to 3 inches with chopped sphagnum and leaf-mold mixed with coarse sand or pulverized coal-clinkers. Keep the moss in a growing condition. (Wm. Mathews.)

E. *Dorsal sepal broadly ovate, lined*..... 8. *longifolium*

EE. *Dorsal sepal narrowly ovate, reticulate*..... 9. *Boissierianum*

BB. *Fls. appearing simultaneously; petals caudate, many times longer than sepals*..... 10. *caudatum*

1. *Schlímii*, Rolfe (*Cypripedium Schlímii*, Lind. *Selenipedium Schlímii*, Reichb. f.). Fig. 2926. Lvs. 4-6, ligulate, leathery, sharp-pointed, 9-12 in. high; scape longer than the lvs., hirsute, often branched, 2-8-fld.; sepals less than 1 in. long, ovate obtuse, the lower a little larger than the upper and concave, white or spotted with crimson on the inner side; petals like the sepals; labellum an elliptic bag with a contracted opening, white with a large crimson blotch in front; staminodium yellow. Late summer. Colombia. B.M. 5614. F.S. 18:1917. Var. *albiflorum*, Hort. Fls. white, except the yellow staminodium and a

2929. *Phragmopedilum Dominicanum*. ($\times \frac{1}{4}$)
(Hybrid; supplementary list, page 2604)

suffused blotch on the labellum. I.H. 21:183. Vars. *gigantëum* and *supërbum* are also advertised.

2. *Lindleyanum*, Rolfe (*Cypripedium Lindleyanum*, Schomb. *Selenipedium Lindleyanum*, Reichb. f.). Lvs. 15–20 in. long, leathery, deep green, with yellow margins; scape many-fl., pubescent, 2–4 ft. high: upper sepal ovate-oblong, undulate, light green with brownish veins; petals 2 in. long, deflexed, green with brown veins, ciliate; labellum olive-green, with brown veins and much spotted on the side lobes. Guiana. G. W. 13, p. 570.

3. *Sargentianum*, Rolfe (*Selenipedium Sargentianum*, Rolfe). Fig. 2927. Lvs. tufted, 6–8 in. long, oblong-lanceolate, acuminate, with golden margins; scape 6 in. high, 2–3-fl.: dorsal sepal oblong, acute, pale yellow with red veins; lower sepal ovate, subacute, shorter than the lip; petals longer than the sepals, strap-shaped, slightly twisted, undulate, ciliate, pale yellow streaked with red and with bright red margins; labellum yellow, with pale red veins, deflexed side lobes speckled with red. Brazil. B. M. 7446. G.C. III. 15:781. A. G. 21:423.

4. *carcinum*, Rolfe (*Cypripedium Pearcet*, Hort. *C. carcinum*, Lindl. & Paxt. *Selenipedium carcinum*, Reichb. f.). Lvs. 1 ft. long, springing in sedge-like tufts from the long creeping rhizome: scape longer than the lvs., 3–6-fl.: fls. mostly pale greenish, with the segms. bordered with white and having purple tips; sepals broadly ovate, waved, as long as the lip; petals more than twice as long, pendent, narrow, and much twisted; labellum oblong, the upper margins flat; staminodium provided with 2 hairy processes. Peru. B. M. 5466. F.S. 16:1648.

5. *Klotzschianum*, Rolfe (*Cypripedium Schomburgkianum*, Klotzsch. *Selenipedium Klotzschianum*, Reichb. f. *S. Schomburgkianum*, Debois). Lvs. linear, 6–12 in. long, scarcely $\frac{1}{2}$ in. wide, rigid, keeled; scape longer than the lvs., hirsute, purple, 2–3-fl.: dorsal sepal ovate-lanceolate, pale rose-colored, with reddish brown veins, the lower ovate, boat-shaped, colored like the upper one; petals $3\frac{1}{2}$ in. long, linear, twisted, colored like the sepal; labellum greenish yellow, the inflexed side lobes whitish, spotted. British Guiana. B. M. 7178. G.C. III. 15:625.

6. *vittatum*, Rolfe (*Cypripedium vittatum*, Vell. *Selenipedium vittatum*, Reichb. f.). Lvs. 1 ft. long, linear-ligulate, acute, margined with yellow: sts. few-fl., 12–18 in. high: dorsal sepal oblong, subacute, greenish striped with red; lower sepal about twice as broad as the upper, green; petals linear, pendent, undulate, reddish brown, striped with green and green

toward the base, longer than the sepal; labellum shorter than the sepals, brown, greenish spotted with reddish brown inside. Brazil. I.H. 23:238.

7. *Hartwegii*, Pfitz. (*Cypripedium Hartwegii*, Reichb. f. *Selenipedium Hartwegii*, Reichb. f. in part). Lvs. broadly ovate, much attenuated at apex; scape glabrous, many-fl.: dorsal sepal oblong, acute, pale green, with rosy veins and whitish margin; petals linear-ligulate, from a somewhat cordate base, velvety-glandulose on the inside toward apex, pale yellow-green with rose-pink border; lip yellowish green, tinged brown in front, the inflexed margins dotted with rose. Peru.

8. *longifolium*, Rolfe (*Selenipedium Roezlii*, Reichb. f. *S. Hartwegii*, Reichb. f. in part. *Cypripedium longifolium*, Warscz. and Reichb. f. *C. Roezlii*, Regel). Lvs. tufted, 8–12 in. long, narrowly strap-shaped, tapering to point, strongly keeled; scape 2 ft. high, purplish, sparingly pubescent: fls. large; upper sepals ovate-lanceolate, pale yellowish green, faintly streaked with purple; lower sepals ovate, obtuse, shorter than the lip; petals $3\frac{1}{2}$ in. long, spreading, narrowly lanceolate, twisted, pale yellow with rose-colored margins and with a white line on the edge; labellum 2 in. long, green shaded with dull purple or brown in front, side lobes yellow, spotted with pale purple. Costa Rica. B. M. 5970, 6217. I.H. 20:138. R.H. 1873, p. 416; 1893, pp. 18, 19. F. M. 1874:119. F. 1871:126.—*S. Roezlii*, sometimes considered as a distinct species, is of more robust habit, having lvs. 2 ft. long and green scapes. Var. *magniflorum*, Hort. (*Cypripedium magniflorum*, Hort.), has the petals margined with white. A.F. 7:707. The following varieties also are distinguished in cult.: *grandiflorum*, *latifolium*, and *roseum*.

9. *Boissierianum*, Rolfe (*Cypripedium reticulatum*, Reichb. f. *C. Boissierianum*, Reichb. f. *Selenipedium Boissierianum*, Reichb. f.). Plant of vigorous habit: lvs. about 3 ft. long, acuminate: scape few-fl. or sometimes paniculate, 3–7-fl.: fls. of peculiar light green tints, with a few sepia-brown and green blotches on the whitish inflexed part of the lip and with some brown spots on the margins of the sepals; ovary dark brown, with green apex and ribs; upper sepals ligulate-lanceolate, very crisp; lower sepals oblong, about equal to the labellum, crisp; petals spreading, long-linear, twisted and very crisp on the margins. Peru. G.C. III. 1:143; 21:54, 55. G.F. 4:603. J.H. III. 55:51.

10. *caudatum*, Rolfe (*Cypripedium caudatum*, Lindl. *C. Lindenii*, Van Houtte. *C. Warsceviczianum*, Reichb. f. *Selenipedium caudatum*, Reichb. f.). Lvs. strap-shaped, rather stiff upright, about 1 ft. long; scape 12–24 in. high, about 4-fl.: dorsal sepals 5–6 in. long, lanceolate, pale yellow, verging on creamy white and veined with greenish, lower sepal similar; petals pendent, twisted, often attaining a length of nearly a yard, yellowish, shaded with brown on the outside and becoming brownish crimson toward the tips. Peru. F.S. 6:566. R.H. 1857, p. 318; 1883, p. 351; 1885, p. 472. G.C. II. 3:211; 26:269. Gn. 3, p. 313; 26, p. 72; 32, p. 301; 46, p. 85. A.F. 3:132; 6:859; 35:479. R.B. 24:25. Gng. 5:265. G.M. 31:557; 33:795; 35:489.—One of the largest of the genus and remarkable on account of the extremely long petals. Peloric forms with the third sepal (labellum) resembling the other two have passed under the name of *Uropedium Lindenii*, Lindl. Var. *roseum*, Hort. (*Selenipedium caudatum* var. *Warsceviczii*, Godfroy.). Sepals yellow, with orange veins; petals deep purple; labellum deep yellow in front, green behind. I.H. 33:596. Var. *Wallisii*, Hort. (*Selenipedium Wallisii*, Reichb. f. *Cypripedium Wallisii*, Hort.). Lvs. paler green: fls. pale, and in every way more delicate than the type. Gn. 49, p. 140. G. 19:34. Numerous other varieties of this species are distinguished in cult. The following names occur in trade lists: *albreum*, *luxemburgense*, *rubrum*, *supërbum*, *Seegerii*, *splëdens*, *nigrëscens*, Hort.

(Hybrid; supplementary list,
page 2604.)

P. Ainsworthii, Rolfe & Hurst. (Cyrtipedium Ainsworthii, Reichb. f. Selenipedium Ainsworthii, Reichb. f.). Fig. 2923. Hybrid between *P. longifolium* × *P. Sedenii*. Lvs. ligulate, acuminate, 1½ ft. long; scape shorter, pubescent, few-fl.; upper sepal oblong, acutish, undulate, whitish or yellowish green with a pale purple border; lower sepal very broad and concave with a reflexed margin, shorter than the lip; petal broad, purple, with a green midvein and a pale area near the base; side lobes of the lip yellow, with numerous spots.—*P. alboburpureum*, Rolfe & Hurst. (Cyrtipedium alboburpureum, Reichb. f. Selenipedium alboburpureum, Reichb. f.)= *P. Dominianum* × *P. Schlimii*. Fls. larger than those of *P. Sedenii*; sepals oblong, acute, whitish with a purplish tinge on margins; petals 5-6 in. long, pendent, twisted, purplish, lip purplish on borders, the white infolded margin purple-spotted. Gn. 21, p. 332. J.H. III. 52:69.—*P. Brönnii*=*P. longifolium* × *P. Sedenii*.—*P. Brönnii leucoglossum*.—*P. Brysa*.—*P. Boissierianum* × *P. Sedenii*.—*P. Calurum*=*P. longifolium* × *P. Sedenii*. Fls. large, about 5 in. across petals; dorsal sepal oblong-ovate, pale green, with longitudinal purplish ribs, flushed red on outside; petals lanceolate, undulate, pale green in the center and at the base, margins rose-red; labellum oblong, rose-red tinted with brown in front; side lobes deeply inflexed, cream-white, with irregular spots of purple. G.Z. 29:241. F. 1884:145.—*P. cardinale*, Reichb. f. (Cyrtipedium cardinale, Reichb. f.)= *P. Schlimii* × *P. Sedenii*. Lvs. long, straight; dorsal sepal bluish-white, slightly streaked with green; petals broad, ovate-oblong, undulate, white tinged with rose-purple near the base; labellum intense purple; staminodium white. Gn. 27:520.—*P. Chlorops*=*P. caricinum* × *P. longifolium*.—*P. Cleola*=*P. Boissierianum* × *P. Schlimii*.—*P. conchiferum*=*P. caricinum* × *P. longifolium*.—*P. Penclans*=*P. Calurum* × *P. caudatum*.—*P. Perseus*=*P. Lindleyanum* × *P. Sedenii*.—*P. porphyreum* (Cyrtipedium porphyreum, Reichb. f.)= *P. longifolium* × *P. Sedenii*. Lvs. broadly strap-shaped, acute, about 1 ft. long; fls. mostly purple, resembling those of *P. Sedenii*, but without protuberances on the open sides of the lip. The sepals and petals are oblong and more acuminate.—*P. Saundersianum*=*P. caudatum* × *P. Schlimii*.—*P. Schroederæ* (Cyrtipedium Schroederæ, Hort. Veitch, ex-Reichb. f.)= *P. caudatum* × *P. Sedenii*. Plant of the habit of *P. Sedenii*, with fls. resembling those of *P. albo-purpureum* but larger; upper sepals nearly ochre-colored, with purple veins; lower sepals very broad, ochre-colored, with purple veins; petals long-lanceolate, undulate, pendent, 4 in. long, greenish white in the middle, crimson-purple around the margin; labellum purple outside, inflexed lobes yellow, with brown blotches.—*P. Sedenii* (Fig. 2930)=*P. longifolium* × *P. Schlimii*. Lvs. numerous, crowded, 12-18 in. long, tapering to a point; scapes 12-18 in. high, about 4-fid. but often sending out secondary flowering branches from the axils of the bracts after the first fls. have fallen; fls. 3½-4 in. across the petals; lower sepal oval, greenish white, upper sepal oblong, acute, with faint purplish green veins; petals lanceolate, twisted, purple shading to greenish white at the base; labellum rich crimson-purple shading to paler purple behind, spotted inside. A very luxuriant free-flowering plant. F.M. 1876:206; 1878:302. R.H. 1879:470. G.Z. 21:1. O. 1910, p. 88. Var. *candidulum*, Reichb. f. Sepals white; petals white tinged with rose; labellum darker rose. The following names are also in the trade: *grandiflorum*, *sanguineum*, *superbum*.—*P. tenellum*=*P. longifolium* magnificum × *P. Schlimii*.—*P. Titanum*=*P. Lindleyanum* × *P. longifolium*.—*P. Uranus*=*P. grande* × *P. Lindleyanum*.—*P. urgrande*=*P. Lindleyanum* × *P. longifolium*.—*P. Weidlichianum*=*P. longifolium* × *P. Schlimii*. G.M. 34:274.

GEORGE V. NASH.

PHRYMA (one of the many names which Linnaeus never explained). *Phrymaceæ*. One genus and one species comprises the family. It is a hardy perennial herb of little horticultural value.

Erect, divaricately branching, with coarsely toothed ovate lvs. and small purplish or rose-colored opposite small fls. borne in long slender terminal spikes. It seems to have been rarely cult. in Eu. and offered in America by dealers in native plants. *Phryma* has been considered an outlying member of the verbenaceæ family. This is because its ovary is 1-celled, while others of the Verbenaceæ, as a rule, have a 2- or 4-celled ovary. There is some evidence for regarding it as a 2-celled

verbenaceous plant in which only half the ovary develops. This plant has the infl. of the verbenaceæ tribe and the habit of *Priva*. Ovule solitary, erect, orthotropous, laterally affixed at the base; seed without albumen; cotyledons convolute; radicle superior; stamens 4, didynamous; style slender and stigma 2-lobed.

Leptostachya, Linn. LOPSEED. Height 2-3 ft.: lvs. 3-5 in. long, thin, the lower long-stalked; fls. at first erect, soon spreading, and the calyx in fr. closed and abruptly deflexed against the axis of the spike, the teeth long, slender, and hooked at the tip. June-Aug. Common in moist and open woods, New Bruns. to Man., south to Fla. and Kans.; also E. Asia.—This very widespread and relatively unattractive plant has stimulated considerable speculation on the problem of the distribution of plants. Horticulturally, it may be worthy a place in the wild-garden for its botanical interest. The mature calices adhere to clothing, like a bur, by the hooked tips of the teeth. L. H. B.

PHRYNIUM (from Greek word for toad, because the plant inhabits marshes). *Marantaceæ*. Maranta-like plants with creeping rootstocks and large oblong showy radical leaves.

The genus is closely allied to *Calathea* and *Maranta* and is often confused with them. The Marantas are New World plants with 1 seed-bearing locule in the fruit, whereas *Calathea* and *Phrynium* have 3-seed-bearing locules, or at least a 3-celled ovary. In *Calathea*, the fl.-cluster is terminal on a leafy st. or rarely on a leafless scape arising directly from the rhizome; in *Phrynium*, the cluster is lateral from the sheathing petiole. In *Calathea* the corolla-tube is usually slender; in *Phrynium* it is usually short.—Species 14 and a few others of doubtful position are admitted to the monograph by Schumann in 1902 (Engler's *Das Pflanzenreich*, iv. 48), and other species have been described since then; they are native in India, Malasia to New Guinea.

Phryniums are grown the same as *calatheas* and *marantas* (which see). *P. variegatum*, N. E. Br., is probably a variegated form of *Marantia arundinacea*. It is a stove plant of dwarf habit with ovate-lanceolate acuminate green lf.-blades which are marked with cream-white or white stripes and bands. I.H. 33:606. F.R. 3:469. Gt. 46, p. 581. J.H. III. 28:27; 61:560. It is a worthy plant, now coming to be popular. *P. Micholitzii*, Hort. Lvs. broadly oblong, about 10 in. long, acute, green and broadly white-striped above from the midrib outward, paler beneath, midrib claret-red, petiole red. New Guinea. G.C. III. 33:suppl. April 18. R.H. 1903, p. 226. *P. floribundum*, Lem., is *Calathea violacea*, Lindl., a tall species with oblong or oblong-lanceolate lvs. green above and purplish and glaucescent beneath and violet-colored fls., from Brazil. B.R. 961. L.B.C. 12:1148. For *P. eximium*, see *Calathea eximia*.

L. H. B.

PHYGELIUS (Greek, *sun flight*, because it was said to love the shade). *Scrophulariaceæ*. Small South African shrubs, hardy South and useful in greenhouses, something like pentstemon.

Plants erect, glabrous or nearly so: lvs. opposite, stalked, crenate-dentate; fls. many, long and tubular, scarlet, with exserted stamens in 2 pairs, and a long, filiform declined style; calyx 5-parted; corolla trumpet-shaped, the limb with 5 short nearly equal blunt lobes; fr. a many-seeded caps.—Species 2.

capensis, Meyer. CAPE FUCHSIA. Fig. 2931. Two to 3 ft., becoming woody at the base, glabrous, the st. with 4 angles or narrow wings: lvs. ovate to ovate-lanceolate, rounded at the base, firm and veiny, bluntly small-toothed; fls. slender, 2 in. long, somewhat curved, 2-lipped, purple-scarlet, 1-4 together on the ends of straight-spreading peduncles, drooping. Cape of Good

Hope. B.M. 4881. R.H. 1857, p. 599; 1886, p. 473. F.S. 11:1111. R.B. 25:36. G. 4:607; 35:591. Gt. 7:168. G.W. 13, p. 91.—A fine subshrub blooming in summer and hardy in protected places as far north as Philadelphia. In the N. it is known as a greenhouse plant. It is excellent for planting out, enduring heat and dry weather as well as geraniums, or even better. It is prop. by seeds and also by cuttings. The cuttings may be taken from the late autumn shoots of outdoor plants. *Phygelius* is a showy plant, deserving to be better known.

P. æqualis, Harv. Infl. closer, the pedicels much shorter; calyx-segms. lanceolate or nearly oblong rather than ovate or oblong-lanceolate; corolla-tube nearly straight, about equal rather than oblique at apex; described as a handsome shrub with habit of a fuchsia. Transvaal to the eastern region of S. Afr., whereas *P. capensis* is more of the coast and central region, although reaching the Kalahari. Apparently not in cult.

L. H. B.

PHÝLICA (old Greek name, now transferred to these plants). *Rhamnaceæ*. Evergreen shrubs, rarely trees: lvs. alternate, crowded, ovate, lanceolate or linear: fls. small, axillary or in dense crowded heads or spikes; calyx obconical, urceolate or cylindrical, 5-cleft, its limb persistent; petals wanting or bristle-like or cucullate; stamens 5; ovary 3-celled: fr. inferior, crowned by the permanent calyx. S. Afr. Prop. by cuttings of half-ripened shoots. *P. plumosa*, Thunb. Branches and twigs pubescent: lvs. linear-lanceolate, smooth above, tomentose beneath with revolute margins: spike oblong or roundish; bracteoles villous, twice as short as the tubular minutely pilose calyx, hairs of the tube reversed, appressed, segms. ovate-lanceolate. S. Afr. G.W. 10, p. 306. *P. ericoides*, Linn. Branches fastigiate; twigs thinly pubescent: lvs. short-petioled, spreading or erectish, linear or linear-subulate: infl. terminal heads on the rather umbellate twigs; fls. small; involucre hemispherical, its scales ovate, foliaceous, cuspidate; calyx turbinate, smooth, longer than the very villous bracteoles, segms. ovate, acute, hirsute; petals concave, cucullate: fr. a smooth caps. S. Afr. G.W. 10, pp. 305, 306.

PHYLLÁGATHIS (Greek, probably alluding to the involucre head). *Melastomaceæ*. Greenhouse woody plants, with ornamental foliage and attractive flowers.

Plants with short thick sts.: lvs. opposite or the terminal solitary, large, petioled, roundish, cordate at the base, entire or denticulate, prominently nerved: fls. crowded into a short-peduncled sometimes involucre head, rosy, about $\frac{1}{2}$ in. across; petals 4, rarely 3; stamens 8, rarely 6; ovary 4-celled, rarely 3-celled: caps. top-shaped, 4-valved.—Species a half-dozen and more, Malay Archipelago and China. The lvs. of *P. rotundifolia* are praised for their colors, both above and below, their venation, their plaited character, and their strong shadows and reflected lights. The lvs. are glossy green above, tinted along the curved nerves with metallic blue and purple; beneath they are a rich coppery red, with the prominent nerves of a brighter color. For the general cult. of melastomeaceous plants, consult *Melastoma* and *Medinilla*.

These are very ornamental stove perennials. Their cultural requirements from March to the end of summer call for a high temperature. From the end of February and through March the night temperature should stand at 65°; this may be gradually increased until it reaches 70° to 75° the middle of May. This high temperature should be held until the autumn, when it may be gradually reduced until the plants are held at about 60° for December and January. As the temperature is raised and the days become longer, increase the syringing, which will provide a moisture that greatly benefits this class of plants. In the spring and summer, they will require plenty of water at the roots. Give ventilation, to keep the temperature at the right mark, but not so as to cause cold drafts to strike the plants, otherwise they may be seriously injured.

In the spring and summer, the plants will need shading, but not too heavy as it will make the foliage soft. Late in autumn and winter they will stand full sun. Any renewing of the earth or compost or repotting should be done about the middle of February. A good compost to use is a fibry loam four parts, fibry peat one part, well-decayed cow-manure one part, and a moderate quantity of sand to make it open.—The plants may be increased by half-ripened wood or by

leaf-cuttings taken in February or March.

For wood cuttings, start a few old plants early and when the growth shows half-ripeness the cuttings may be taken off with three joints and placed in small pots, using a mixture of loam, peat, and sand in equal parts. These pots may

be placed in a warm propagating-bed, where they have a bottom heat of 80° to 85° and by covering with glass, kept shaded and moist, they will soon root. Leaf-cuttings may be placed in a warm propagating-bed, inserting the petiole in the sand; see that the under part of the leaf lies flat on the sand. Keep shaded and moist and they will show growth

in different parts of the leaf. Another way to root them is when they have pushed out side growth of 2 or 3 inches, cut a piece of the woody stem with the young growth and insert in pots and plunge where they can have bottom heat. After they are rooted and potted, place them where they will get a fair amount of

2931. *Phygelius capensis*.
($\times \frac{1}{2}$)

light, and keep the atmosphere moderately humid, shading when the sun becomes too strong. Grown on by shifting until they are in 8- or 10-inch pots, they will produce good and satisfactory plants. (J. J. M. Farrell.)

rotundifolia, Blume. St. short and thick, rooting at intervals, 4-sided, dark purple: lvs. 6 in. or more by $4\frac{1}{2}$ in., roundish ovate, abruptly acuminate, denticulate, 10-ribbed lengthwise, plaited above; floral parts in 3's or 4's, in a many-fl. head: fls. reddish, subtended by dark purple scales. Sumatra. B.M. 5282.

P. gymnantha, Korth. St. short: lvs. cordate-ovate, glossy green, ciliate, 7-nerved: fls. pink, in a close head; petals lobed. Borneo.—*P. hirsuta*, Cogn. Differs in floral characters: calyx-lobes very short and broadly rounded; petals obovate and rounded; ovary adherent to calyx: lvs. cordate-ovate or broader, with 3 pairs of curving lighter-colored side veins and also banded crosswise: infl. standing higher than the handsome lvs. Borneo. L.H. 41:3.

WILHELM MILLER.
L. H. B.†

PHYLLÁNTHUS (Greek for leaf-flower, the flowers of some species being apparently borne on leaves). *Euphorbiaceæ*. Mostly shrubs, some herbs or trees, often cultivated in greenhouses for their graceful or curious foliage; some species have economic uses for which they are cultivated in tropical lands.

Leaves small, alternate, entire, usually 2-ranked on

the small lateral branches which then resemble pinnate lvs., such as walnut or sumach, and even fall like lvs., leaving conspicuous scars on the main branches; several species have the branches flattened into lf.-like organs with fls. and rudimentary lvs. on the margins: fls. axillary, apetalous, monöcious or dioecious, in small clusters or singly; sepals 4-6, imbricate; disk present but no rudimentary pistil in the staminate fls.; stamens 2-6 (or more), usually 3; styles slender; ovary 3-celled, 2 ovules in each cell.—About 500 species, mostly in tropical regions. Related to *Breynia*, *Glochidion*, and *Securinega*. Some of the species commonly cult. under the name of *Phyllanthus* belong more properly to *Breynia* or *Glochidion*. The genus has not been thoroughly studied since Mueller monographed it in D.C. Prod. 15, II; 274, where it is divided into 44 sections, some of which, as *Emblica*, *Cicca*, *Bradleia* and *Xylophylla*, have been considered separate genera.

Most of the species here included are grown as ornamental shrubs in the greenhouse. *P. acidus* (*P. distichus*) is often cultivated, especially in the gardens and lowlands of Jamaica and the West Indies for the fruit which is pickled or made into preserves; it is acid and astringent; the root is an active purgative and the seed is also cathartic. *P. Emblica* is also grown in the tropics for the edible fruit. *P. nivosus* is often used in greenhouses and for bedding out in summer, and in the warmer parts of Florida for permanent hedges.

In general, *phyllanthus* is propagated from green-wood cuttings from the larger side shoots rooted in sand in the hothouse. They are usually taken in August or before. Some leaves are left on the cutting and the sand is kept just moist but not allowed to dry. The snow-bush grows readily from root cuttings. *P. acidus* and *P. Emblica* and some other species are often grown from seeds; the latter is difficult to propagate vegetatively except by layering.

A. Branches terete or angled: lvs. well developed.

B. Lvs. not distinctly distichous, often variegated.

nivosus, Bull. (*Breynia nivosä*, Small). SNOW-BUSH. Shrub of loose habit, with dark, wiry, somewhat zig-zag branches: lvs. 1-2 in. long, broadly ovate-elliptical, obtuse, white and green variegated, or sometimes all white at the tips of the branches: fls. small, greenish, hanging by long pedicels from the lf.-axils. S. Sea Isls. F.M. 1874:120. I.H. 25:332. G.Z. 18:145. Var. **röseo-pictus**, Hort. Lvs. mottled with pink and red as well as green and white. Gn. 10, p. 261. F. 1878, p. 13. Var. **atropurpureus**, Hort. (*P. purpureus*, Hort.?). Lvs. dark purple. Forms of this species are commonly planted in the tropics.

Ferdinándi, Muell. Arg. Lvs. thick, oblong-ovate, 1-1½ in. wide, 2-3 in. long, bluntly acuminate: fr. about ½ in. thick. Austral.—A good foliage shrub, hardy in S. Calif.

BB. Lvs. distichous on lateral branches, resembling pinnate lvs.

C. Stamens 6-10, filaments united, anthers not opening vertically.

grandifolius, Linn. (*P. juglandifolius*, Willd. *P. werroxfolius*, Hort.). Foliage branches 1-2 ft. long, leaving large scars on the thick main branches when they fall: lvs. thick, oblong-lanceolate, rounded or cordate at base, 1 in. wide, 4-5 in. long: fr. large, 3-celled. W. Indies to S. Amer.—Tall and symmetrical growing, foliage with a metallic luster; hardy in S. Calif.

CC. Stamens 2-4.

D. Sepals of staminate fls. 5-6; anthers opening vertically; filaments connate.

Émblica, Linn. EMBLIC. MYROBOLAN. A much-branched shrub or small tree: foliage branches 3-12 in. long, with 100 or more linear-elliptical, obtuse lvs. close together and about ½ in. long: fls. small, short-

pedicelled, in the axils of the lower lvs: styles connate, caps. baccate, ¾-1 in. diam. Trop. Asia. L.B.C. 6:548. —Fr. used raw or preserved: foliage handsome, resembling fir or hemlock: lvs. and bark rich in tannin.

longifolius, Lam. Low shrub: lvs. ½-1 in. long, linear: fls. small, short-pedicelled, axillary; styles nearly free. Mascarene Isls.—Hardy in S. Calif.

DD. Sepals of staminate fls. 4; anthers not opening vertically.

ácidus, Skeels (*Averrhoa ácida*, Linn. *Cicca disticha*, Linn. *P. distichus*, Muell. Arg. *P. Cicca*, Muell. Arg. OTAHEITE GOOSEBERRY. WEST INDIA GOOSEBERRY STAR GOOSEBERRY. JIMBLING. Fig. 2932. Shrub or small tree, up to 20 ft. high, main branches stout and marked by scars of fallen foliage-branches: lvs. ovate, acute, 1-2 in. long: fls. usually on separate branches below the foliage, sometimes in the lf.-axils: fr. ¾ in. long, thick, fleshy. India and Madagascar.

2932.
Phyllanthus acidus—
Otaheite gooseberry.

púlcher, Wall. (*P. pallidifolius*, Muell. Arg. *Rèidia glaucescens*, Miq.). Small shrub, foliage branches straight, with 25-40 lvs.: lvs. ½ in. long, ovate-elliptical, apiculate, pale green above, glaucous beneath: fls. small, red and yellow, drooping on pedicels 1 in. long. Malay region. B.M. 5437. G.F. 4:161. Gn. 67, p. 83.

AA. Branches flattened into lf.-like organs, with the fls. and rudimentary lvs. along their margins.

speciosus, Jacq. (*P. Arbúscula*, Gmel. *P. latifolius*, Hort. *Xylophylla latifolia*, Sims). SEASIDE LAUREL. Small shrub: floriferous branches lanceolate, striate, crenate, ½-1 in. wide, 2-4 in. long: fls. whitish, striate, pedicels slender. Sept. Jamaica. B.M. 1021.

angustifolius, Swartz (*P. elongatus*, Steud. *Xylophylla elongata*, X. *montana*, Sims). Similar to *P. speciosus*, the floriferous branches narrower, ¼-½ in. wide, 3-6 in. long: fls. red. July. W. Indies. B.M. 2652. L.B.C. 1091.

P. acuminatus, Vahl, related to *P. distichus*. Trop. Amer.—*P. carolinénsis*, Walt., an infrequent low weed from Pa., south.—*P. Chantrieri*, André, related to *P. pulcher*. Cochín-China. R.H. 1883, p. 537.—*P. epiphyllanthus*, Linn., related to *P. angustifolius*, the flat branches curved. B.R. 373.—*P. falcatus*, Swartz=*P. epiphyllanthus*.—*P. glaucescens*, HBK., related to *P. pulcher*. Trop.

Amer.—*P. isolepis*, Urban, similar to *P. speciosus*, but the flat branches tend to be rhomboid.—*P. linearis*, Swartz, related to *P. angustifolius*. W. Indies.—*P. mucronatus*, HBK.=*P. acuminatus*.—*P. Niruri*, Linn. A tropical weed with lvs. like *P. Emblica*.—*P. salviaefolius*, HBK., related to *P. pulcher*. S. Amer. R.H. 1883, p. 176.—*P. Seemannianus*, Muell. Arg. Fiji Isls.—*P. turbinatus*, Sims = *Breynia turbinata*.—*P. zeylanicus*, Muell. Arg.=*Glochidion zeylanicum*, A. Juss, which is a small tree of Malaya, with coriaceous elliptic-oblong or oblong-lanceolate lvs., and depressed caps. often nearly 1 in. long.

J. B. S. NORTON.

PHYLLOUREA: *Codiaeum*.

PHYLLITIS (Greek, *a leaf*, from the simple foliage). *Polypodiaceæ*. A group of ferns, including several or only the following species, according to different fern students. Lvs. simple, strap-shaped, with the sori almost at right angles to the midrib, grouped in pairs on contiguous veins, the indusia facing together.

Scolopendrium, Newman (*Scolopendrium vulgare*, Smith. *S. officinarum*, Hort.). HART'S TONGUE. Lvs. 10–15 in. long, cordate at base or sometimes long-eared, 1–2 in. wide, herbaceous, in tufts sometimes of 50 or more lvs. Probably the rarest wild fern in Amer., growing only in three localities in Tenn. and N. Y., and near Owen Sound, Ont. Its usual habitat in Cent. N. Y. is on steep rubble limestone slopes, where it roots among loose stones, usually hidden by jewel-weed. In England it is a common wall fern, and has given rise to more than a hundred varieties, some of the commonest of which are listed below. One or two American dealers offer the species for sale. The differences between the numerous English forms depend mainly on differences in the crispiness and forking of the lvs. and on combinations of these two features. The following varieties are offered commonly in England under *Scolopendrium vulgare*: vars. *Drummondæ superba*, *crispum*, *crispum multifidum*, *crispum muricato-fimbriatum*, *ramo-cristatum*, *Dædalea*, *sagitto-grandiceps*, Hort.

R. C. BENEDICT.

PHYLLOACTUS: *Epiphyllum*.

PHYLLÓCLADUS (Greek, *leaf branch*, referring to the phyllodia which are characteristic). *Taxaceæ*. Trees or shrubs: branches often whorled; branchlets flattened and expanded into rigid and coriaceous toothed or lobed lf.-like cladodia: true lvs. reduced to linear scales: fls. monœcious or dicecious, the male fls. fascicled at the tips of the branchlets, the female fls. sessile on the margins of the cladodia or on peduncle-like divisions of the same: ovuliferous scales 1 or several, thick and fleshy, free.—Six species, Malaya to the Philippines and New Zealand. *P. rhomboidalis*, L. C. Rich. (*P. asplenifolius*, Hook. f.). Tree up to 60 ft., or shrub on mountain tops: persistent branches more or less reticulate, cladodia or deciduous lf.-like branchlets cuneate or rhomboidal: lvs. very small, subulate: male catkins 2 or 3 together; female catkins globular, with 1, 2, or 3 fertile scales surmounted by 1 or 2 barren ones. Austral. Occasionally seen in Calif. gardens and eastern conservatories. The following species have also been cult.: *P. glaucus*, Carr., New Zeal., *P. hypophylla*, Hook. f., Borneo, and *P. trichomanoides*, D. Don., New Zeal.

PHYLLÓDOCE (after Phyllodoce, a sea-nymph mentioned by Vergil). *Ericaceæ*. MOUNTAIN HEATH. Ornamental low shrubs grown for their handsome flowers.

Evergreen prostrate and ascending shrubs: lvs. alternate, crowded, linear: fls. in terminal umbels, or axillary, nodding on slender pedicels; calyx 5-parted, small; corolla urceolate or campanulate, 5-lobed; stamens 10: fr. a many-seeded caps., dehiscent into 5 valves.—Six species in arctic regions of N. Eu. and N. Asia, in N. Amer. in the Rocky Mts. south to Calif. Often united with *Bryanthus*, which is easily distinguished by its 4-cleft rotate corolla.

The mountain heaths are heath-like, with small

leaves and handsome delicate flowers often appearing in great profusion. They are perfectly hardy, but do not thrive under ordinary conditions; they are best grown in a rockery in peaty and moist soil shaded from the mid-day sun and they like cool and moist air. The hybrid *P. erecta* is more vigorous and less particular; it is therefore better known in cultivation than the true species. Propagation is by seeds in spring in peaty soil or cut sphagnum and kept moist and shady, also by cuttings in August under glass or by layers.

AA. *Corolla urceolate* (urn-shaped).

cærûlea, Babington (*Menziësia cærûlea*, Swartz. *Bryanthus taxifolius*, Gray. *B. cærûleus*, Dipp.). To 6 in. high: lvs. slightly glandular while young, later glabrous, $\frac{1}{4}$ – $\frac{1}{2}$ in. long: fls. 2–6; calyx pubescent; corolla oblong-urceolate, $\frac{1}{3}$ in. long, glabrous, purple, turning bluish in drying. June–Aug. N. Asia, N. Eu. and boreal N. Amer. L.B.C. 2:164. S.B.F. (ed. 3) 6:886. G.W. 17, p. 261.

AA. *Corolla campanulate* (bell-shaped).

empetrifórmis, Don (*Bryanthus empetrifórmis*, Gray. *Menziësia empetrifórmis*, Smith). Five to 8 in.: lvs. glabrous, $\frac{1}{4}$ – $\frac{1}{2}$ in. long: fls. 6 or more; pedicels slender, glandular; calyx glabrous; corolla campanulate, rosy purple, about $\frac{1}{4}$ in. long. May–July. Brit. Col. to Calif. B.M. 3176. C.L.A. 21, No. 11:41. Var. *amabilis*, Rehd. (*P. amabilis*, Stapf). Fls. smaller, broadly campanulate, whitish or pinkish; anthers short. B.M. 8405. Var. *alba*, Hort. Fls. white. Var. *polifolia*, Hort. Taller: fls. purple.

erecta, Drude (*Bryanthus erectus*, Lindl. *Phyllothamnus erectus*, Schneid.). Hybrid between the preceding species and *Rhodothamnus Chamæcistus*. Six to 10 in.: lvs. slightly serrate, glabrous, $\frac{1}{2}$ in. long: fls. 2–10, corolla rotate-campanulate, rosy pink, $\frac{1}{2}$ in. across. F.S. 7:659. J.F. 1:58.—Originated about 1845 in the nursery of Cunningham & Fraser, at Comely Bank, Edinburgh.

P. Brèweri, Heller (*Bryanthus Breweri*, Gray). Allied to *P. empetriformis*. Corolla larger, divided to the middle; stamens exserted; fls. axillary, forming terminal spikes. Calif. B.M. 8146. —*P. glanduliflorus*, Howell (*Bryanthus glanduliflorus*, Gray). Allied to *P. cærûlea*. Lvs. glandular: fls. ovate-urceolate, sulfur-yellow, pubescent outside. Ore. to Alaska and Sitka.

ALFRED REHDER.

PHYLLÓSTACHYS: *Bamboo*.

PHYLOTÆNIUM: *Xanthosoma*.

PHYMATODES (Greek, *a close network*). *Polypodiaceæ*. A group of stove ferns allied to *Polypodium* and sometimes united with that genus, but differing in the fine copious irregular areoles formed by the anastomosing veinlets and the free included veinlets spreading in every direction. For culture, see *Fern*.

AA. *Lvs. simple*.

Swartzii, Underw. (*Polypodium Swartzii*, Baker). Lvs. 2–4 in. long, $\frac{1}{4}$ –1 in. wide, narrowed gradually toward both ends: sori in a single row each side of the midrib. Fla. Keys and Trop. Amer.

musæfolium, Blume. Lvs. 1–3 ft. long, 3–4 in. wide, with an acute point, the lower part winged to the base; main veinlets very distinct, forming rectangular meshes, with numerous small sori almost covering the whole surface. E. Indies.—Known also as *Drynaria* and *Polypodium musæfolium*.

AA. *Lvs. deeply pinnatifid*.

nigréscens, Blume (*Polypodium nigréscens*, Blume). Lvs. 2–3 ft. long, 1 ft. or more broad, cut nearly to the rachis into numerous entire lobes 1–2 in. wide; surfaces naked, dark green; sori in a single row nearer the midrib than the edge, sunk in deep cavities which are prominent as wart-like projections on the upper side. India to Polynesia.

glaucom, Kunze (*Polypodium glaucom*, Kunze). Lvs. 12–18 in. long, 6–8 in. broad, cut down to a winged rachis into entire lobes $\frac{1}{2}$ in. or more wide, both sides naked, glaucous; veinlets indistinct; sori forming a single row close to the midrib. Philippine Isls.—*Phlebodium Mayii*, Hort. (A.G. 19:455. F.E. 10:600), is a horticultural form with crinkly lvs. G.C. III. 23:328, fig. 121.

L. M. UNDERWOOD.

PHYSALIS (Greek for *bladder*, because the thin calyx enlarges and incloses the fruit). *Solanaceae*. **HUSK TOMATO. GROUND CHERRY.** Herbs of warm and temperate countries grown somewhat for the edible fruits and also for the ornament of the great colored fruiting calyx of some species.

Annual and perennial plants, sometimes lightly woody at base, straggling or diffuse in growth, glabrous or pubescent, summer-flowering: lvs. alternate (often opposite or subopposite on short shoots), mostly angled and distinctly petioled, usually soft in texture; fls. not showy, usually on axillary or extra-axillary peduncles, mostly blue or yellowish or whitish; calyx 5-toothed or -cleft, becoming large and bladder-like and inclosing the 2-celled globular yellow or greenish often more or less viscid berry; corolla rotate or short bell-shaped, usually with purplish spots in the center, plicate, short-tubed and mostly 5-toothed; stamens 5; style slender, the stigma somewhat 2-lobed.—Probably 75 species, mostly American, but a few in Eu. and Asia. The species are variable and therefore confusing to the systematist. The genus is allied to *Nicandra*, and more remotely to *Capsicum*, *Lycopersicum* and others.

Most of the species are of little consequence horticulturally, although *P. Alkekengi* and *P. Franchetii* are much prized for the glowing red very large calices, and *P. pubescens* and *P. peruviana* are grown for their edible fruits. Several of the species are known for their fruits where they grow in a wild state, and they may sometimes be transferred to gardens. In most parts of the United States and Canada one or more species grow about gardens, in fields, and in waste places. These species are popularly known as "ground cherry." The fruits are often made into preserves, although they are sometimes eaten raw. The common cultivated species are annuals, or are usually treated as such in this country. They require no extra care. The seeds are sown indoors in the North, in order to secure as much of the crop as possible before frost. Most of the

2933. *Physalis ixocarpa* in its cultivated form. (Fruits $\times \frac{1}{4}$)

cultivated species are long-season plants, and therefore need to be forwarded in the spring. The high colors of *P. Alkekengi* and *P. Franchetii* do not develop until the fruit is ripe; give a warm, sunny exposure; the plants do not withstand frost; let the plants stand 1 to 2 feet apart in the row.

A. Plants with large red calices in fr.

Alkekengi, Linn. **ALKEKENGİ. STRAWBERRY TOMATO. WINTER CHERRY. BLADDER CHERRY.** Diffuse grower, usually with zigzag mostly simple angled setose pubescent sts.: lvs. ovate, with broad base, angular,

2934. *Physalis pubescens*. (Fruits $\times \frac{1}{4}$)

the petiole widening at the top: fls. whitish, the anthers yellow: fr. red (sometimes eaten), the ripe large calyx blood-red and very showy. Seems to be native from S. E. Eu. to Japan, but now adventive or naturalized in many parts of the world; it represents a variable group, from which different forms may be separated. Gn. 41, p. 577; 49, p. 233; 57, pp. 28, 432.—The strawberry tomato is an old garden plant, grown for its highly colored bladders. The plant grows 12–18 in. tall. Of easiest cult. In the N., plants are usually started indoors. It is a perennial, the root withstanding much frost if protected, but it is usually grown as an annual. Not hardy in the northern states.

Franchetii, Mast. (*P. Alkekengi* var. *Franchetii*, Hort.). **CHINESE LANTERN PLANT.** Differs from *P. Alkekengi* chiefly in its greater size, making a plant 2 ft. tall, glabrous, petioles shorter, and bearing calices 2 in. diam.: originally described as an annual, by others said to be sometimes biennial, but apparently perennial; probably variable in duration. Japan. G.C. III. 16:441. Gn. 48, p. 435; 49:232; 57, p. 28; 58, p. 196. G.M. 37:626. J.H. III. 29:343. R.H. 1897:376, and p. 35. R.B. 22:61; 23, p. 91. Gt. 45, p. 636; 46, p. 193. G.W. 4, p. 196. A.G. 18:81. F.R. 1:426.—One of the most profusely advertised novelties of recent years. It is a most striking and showy plant. It was brought to England from Japan by James H. Veitch, and first described with a name by Masters in 1894. In 1879, however, it had been described by Franchet, of the Jardin des Plantes, Paris, as a form of *P. Alkekengi*, but without name. The frs. are very brilliant orange-red in autumn. The berry is said to be edible. It is very likely a variant of *P. Alkekengi*. The plant called *P. Bunyardii*, Hort., is a very free-fruited form, not so robust as *P. Franchetii*, with glowing calices; probably a form of this species or by some suggested as a hybrid with *P. Alkekengi*.

AA. Plants with green or yellow or at most only red-veined calices. Mostly grown for the edible berry.

B. Sts. glabrous or very nearly so.

ixocarpa, Brot. **TOMATILLO.** Fig. 2933. Erect annual, 3 or 4 ft. tall, bearing smooth branches and lvs., the latter thin, ovate or lance-ovate and variously toothed or notched: fls. large and open ($\frac{3}{4}$ in. or more across), the border bright yellow and the throat bearing 5 black-brown spots; anthers purplish: husk or enlarged calyx purple-veined and entirely filled by the

large round, purplish sticky berry, and is sometimes torn open by it. Mex., and intro. northward to the northern states.—The form in cult., described here, is probably *P. capsicifolia*, Dun., now regarded by some as a form of the cosmopolitan *P. angulata*. The writer prefers, however, to refer the plant to *P. ixocarpa*, although there is doubt as to the identity of the cult. plant with this species. Although the cult. plant is sometimes sold as *P. edulis* (erroneously), the frs. are usually too mawkish to be eaten from the hand (at least as grown in the N.). It is a very vigorous and productive plant and is of some consequence as an ornamental, but it is too weedy to be of much value. The fr. is larger than in the native *P. angulata*. The plant figured by Carrière as *P. violacea* (R. H. 1882:216) is the one here described. In Mex., the frs. are said to be used in the making of chilli sauce and as a dressing for meats, usually under the name of "tomatoes." The Mexican forms are confused.

BB. *Sts. pubescent or hairy.*

pubescens, Linn. **STRAWBERRY TOMATO** of vegetable-gardens. **DWARF CAPE GOOSEBERRY.** **HUSK TOMATO.** **GROUND CHERRY.** Fig. 2934. Low annual, trailing flat on the ground, or sometimes ascending to the height of a foot; lvs. rather thin and nearly smooth, more or less regularly and prominently notched with blunt teeth; fls. small ($\frac{3}{8}$ in. or less long), bell-shaped, the limb or border erect and whitish yellow, the throat marked with 5 large brown spots; anthers yellow: husk smooth or nearly so, thin and paper-like, prominently 5-angled and somewhat larger than the small yellow sweetish and not glutinous fr. N. Y. to the tropics.—The plant is very prolific, and the frs. are considerably earlier than in the other species. When ripe the frs. fall, and if the season is ordinarily dry they will often keep in good condition on the ground for 3 or 4 weeks. The frs. will keep nearly all winter if put away in the husks in a dry chamber. They are sweet and pleasant, with a little acid, and they are considerably used for preserves, and sometimes for sauce. The plant is worthy a place in every home-garden. It is grown more or less by small gardeners near the large cities, and the frs. are often seen in the winter markets. The chief objection to the plant is its prostrate habit of growth, which demands much ground for its cult. In good soil it will spread 4 ft. in all directions, if not headed in. The plants are set in rows 3 or 4 ft. apart and 2 or 3 ft. apart in the row. This physalis has been long in cult. It was figured by Dillenius in 1774, in his account of the plants growing in Sherard's garden at Eltham, England. In 1781–6 it was figured by Jacquin, and by him called *Physalis barbadensis*, from the island of Barbados, whence it was supposed to have come into cult. In 1807, Martyn also described it under the name of Barbados winter cherry, or *Physalis barbadensis*, and says that it is a native of Barbados. None of these authors says anything about its culinary uses. Dunal, in 1852, described it as var. *barbadensis* of *Physalis hirsuta*, but later botanists unite Dunal's *P. hirsuta* with Linnæus' *P. pubescens*, of which this common husk tomato is but a cult. form.

peruviana, Linn. (*P. edulis*, Sims). **CAPE GOOSEBERRY.** Fig. 2935. As compared with *P. pubescens*, this is a much stronger grower, the plant standing partially erect and attaining a height of 1½–3 ft.: lvs. thicker, less regularly toothed, more pointed, heart-shaped at the base, and very pubescent or fuzzy; fls. larger ($\frac{1}{2}$ – $\frac{5}{8}$ in. long), open-bell-shaped, the limb or border widely spreading and light yellow, the interior of throat blotched and veined with 5 purple spots, the anthers blue-purple: husk thicker and larger than in the last, somewhat hairy, and has a much longer point. Tropics. B.M. 1068. R.H. 1913, p. 85 (as var. *edulis*).—This species is too late for the northern states. The berry is yellow, not glutinous, and much like that of

P. pubescens in appearance, but it seems to be less sweet than of that species. This plant has been cult. for two centuries, probably. It was described and figured by Morison in 1715 in England. In 1725, Feuillée gave a description of its cult. in Peru, saying that it was then cult. with care and was greatly esteemed as a preserve. The particular form of the species cult. in our gardens is that described and figured by Sims in 1807 as *Physalis edulis*, the "edible physalis." Sims' account says that "this plant is a native of Peru and Chili, but is cult. at the Cape of Good Hope, in some parts of the E. Indies, and more especially at the English settlement of New

2935. *Physalis peruviana*. (Fruits $\times \frac{1}{2}$)

S. Wales, at which latter place it is known by the name of Cape gooseberry, and is the chief fr. the colonists at present possess; is eaten raw, or made into pies, puddings or preserves." The plant is rarely sold by American seedsmen.

L. H. B.

PHYSÀRIA (Greek, *a pair of bellows*, alluding to the didymous fruit and slender style). *Cruciferae*. Perennial herbs, low, canescent: sts. many and spreading: lvs. mostly entire: fls. yellow; calyx inflated, arched, net-veined; petals spatulate to oblong, entire: fr. strongly didymous with a narrow partition; cells inflated, membranaceous, nerveless, several-seeded. Four species, N. W. Amer. *P. didymocarpa*, Gray. Very canescent, about 3 in. high: radical lvs. petiolate with roundish toothed angled or entire blade or oblanceolate and more or less sinuately toothed below; cauline lvs. mostly entire, spatulate: racemes dense; fls. variable in size; sepals lanceolate, surpassed by the rather narrow pale yellow petals: fr. strongly didymous, rather deeply notched above, entire or more or less cordate at base. This species has been intro. abroad, in botanic gardens.

PHYSIANTHUS (Greek, *bladder flower*, referring to the base of the corolla-tube). *Asclepiadaceae*. The plants known to gardeners as *Physianthus* are species of *Araujia*, *Physianthus* now being referred to that genus. They are twiners with showy flowers, grown under glass or in the open in summer.

Including *Physianthus* and *Schubertia* (as is done by Bentham & Hooker), *Araujia* comprises a dozen or more species in the warmer parts of Amer., all with opposite lvs. and whitish or rosy fls.: corolla-tube short or long, inflated at the base; lobes 5, very wide or narrow, overlapping toward the right in the bud; crown with 5 scales attached to the middle of the tube or lower, flat and erect or convex and appressed to the staminal tube: seeds long, bearded. *Schubertia* and *Physianthus* should perhaps be considered as subgenera, the former containing the hairy plants with somewhat funnel-shaped fls.; the latter nearly glabrous plants

with somewhat salver-shaped fls. Schumann, in Engler & Prantl, separates *Schubertia* from *Araujia*, with more than half the species of the combined groups. Under this disposition, *A. graveolens* is transferred from *Araujia*. See *Schubertia*.

The species of *Araujia* resemble in superficial characters the popular *stephanotis*, having the same large white waxy fragrant 5-lobed fls. *A. graveolens*, in particular, has been suggested as a rival to the *stephanotis*, especially as it requires less winter heat, but its foliage when bruised emits a strong and offensive odor, especially with young plants. *A. sericefera* has considerably smaller fls. and is one of the several plants advertised as "cruel plants," because they entrap insects, though they may not digest their dead bodies as in the case of *nepenthes*. These "cruel plants" are mostly members of the milkweed and dogbane families, which have essentially the same kind of floral structure—a highly complicated and specialized type adapted to cross-fertilization by insects. In Fig. 393 of this work, an insect is seen struggling in the clutch of a common milkweed, with a pair of pollen-masses (a), like saddle-bags, which he may extract with one of his legs. *Araujia sericefera* catches moths in a slightly different fashion. See G.C. III. 20:523. For other "cruel plants," see *Cyananchem* and *Vincetoxicum*.

When well grown, *arauias* or *physianthus* bloom freely throughout September and October. They seem to have no special soil requirements and may be flowered outdoors from seed sown indoors in early spring, or they may be kept permanently in a cool greenhouse and grown from cuttings. It is seldom that *A. graveolens* is seen grown well in greenhouses, the plants being usually sickly and infested with mealy-bug. As a summer vine in the open it makes vigorous growth, and after midsummer it usually blooms profusely. The flowers are larger than those of *stephanotis*. Cuttings make the best flowering vines. These may be taken from the ripe wood before cool weather. Seeds are freely produced, and germinate well soon after being sown. *Arauias* are considered hardy in the most favored parts of England, and are grown outdoors in California. *A. graveolens* can be flowered in pots, but the border of the greenhouse is better. (G. W. Oliver.)

The two species likely to be met with in cult. may be characterized as follows: *Araujia graveolens*, Mast. (*Physianthus graveolens*, Hort. *P. auricomus*, R. Graham. *Schubertia graveolens*, Lindl.) Stout, woody climber, densely covered with harsh spreading yellow hairs: lvs. $3-4\frac{1}{2} \times 2-2\frac{3}{4}$ in., obovate, acuminate, greatly narrowed and cordate at the base, hairy on both sides: fls. funnel-shaped, i. e., swollen at the throat, $2-2\frac{1}{2}$ in. across, umbellate. S. Brazil. B.M. 3891. B.R. 32:21. G.C. III. 4:271. See discussion under *Schubertia*.—*Araujia sericefera*, Brot. (*A. albens*, Don. *Physianthus albens*, Mart.). Name originally spelled, by Brotero, *sericefera*, in description and on plate, but usually now written *sericifera*. Nearly glabrous: lvs. $3 \times 1\frac{3}{4}$ in., oblong-acuminate, wide and square at the base, minutely pubescent below: fls. salver-shaped, i. e., not swollen at the throat, pale rose in the bud and only faintly odorous, 1 in. across, cymose. S. Brazil. B.M. 3201. B.R. 1759. G.C. III. 2:653; 20:523. R.H. 1857, p. 89; 1883, p. 488. Gn. 24, p. 409; 34, p. 397. Mn. 6, p. 206. G. 6:363. The plant as above described is the *Physianthus albens* or *Araujia albens* of the trade. *A. hortorum*, Fourn., is probably a form of this species.

WILHELM MILLER.
L. H. B.†

PHYSIC NUT: *Jatropha Curcas*.

PHYSOCARPUS (Greek, *physa*, bladder, and *karpos*, fruit; alluding to the inflated capsules). Syn., *Opulaster*. Rosaceæ, tribe *Spirææ*. NINEBARK. Ornamental shrubs, grown for their white flowers, the attractive inflated pods and the bright green foliage.

Deciduous: bark peeling off in thin strips: lvs. alternate, petioled, stipulate, serrate and more or less lobed: fls. in umbel-like racemes; calyx-tube cup-shaped; sepals 5, valvate; petals white or rarely pinkish, spreading; stamens 20–40; pistils 1–5, more or less united at the base: follicles inflated, opening along both sutures; seeds 2–4, yellowish shining.—Thirteen species have been distinguished in N. Amer. and one in N. E. Asia. Formerly usually referred to *Spiræa*, from which it is easily distinguished by the stipulate lvs., by the inflated follicles and the long glossy seeds; sometimes united with *Neillia*, which differs chiefly in the not inflated pods dehiscent only along the ventral suture, the campanulate or tubular calyx-tube, and in the elongated inflorescence.

The ninebarks are hardy, small or medium-sized spreading or upright shrubs with usually 3-lobed leaves and with umbel-like heads of whitish or sometimes pinkish flowers appearing late in spring, and followed by clusters of small pods, inflated in some species and often assuming a bright red color late in summer. They are well adapted for shrubberies and grow in almost any soil. They propagate easily by either hardwood or greenwood cuttings, also by seeds.

A. Carpels 4–5, rarely 3.

B. Pods glabrous.

opulifolius, Maxim. (*Spiræa opulifolia*, Linn. *Opulaster opulifolius*, Kuntze. *Neillia opulifolius*, Brew. & Wats.). NINEBARK. Fig. 2936. Shrub, to 10 ft. high, with wide-spreading and recurring branches: lvs. roundish ovate, usually cordate at the base, 3-lobed, with the lobes crenately dentate, 1–3 in. long, usually glabrous beneath: corymbs 1–2 in. broad, many-fl.; pedicels and calyx glabrous or pubescent: pods 3–5, inflated, twice as long as the calyx-lobes. June. Que. to Ga., west to Man. and Kans. B.B. (ed. 2) 2:244. R.H. 1912, p. 221. Var. *luteus*, Kirchn. (var. *aureus*, Hort.). Lvs. bright yellow at first, changing to golden bronzy yellow. Var. *Debrichyanus*, Schneid.

(var. "*De Brichy*," Simon-Louis). Lvs. elongated, irregularly lobed, yellowish variegated. Var. *nanus*, Kirchn. Dwarf form with smaller, less lobed, dark green lvs.

BB. Pods tomentose.

amurensis, Maxim. (*Spiræa amurensis*,

Maxim. *Opulaster amurensis*, Kuntze. *Neillia amurensis*, Nichols.). Similar to the former, higher and of more vigorous growth: lvs. 3–5-lobed, with acute or acuminate, doubly serrate lobes, usually pubescent beneath, 2–5 in. long: fls. large, with grayish tomentose pedicels and calyx: pods only one-third longer than calyx-lobes. June. Amurland. Gt. 14:489.

2936. Ninebark.—
Physocarpus opulifolius.
($\times \frac{1}{2}$)

intermedius, Schneid. (*Opulaster intermedius*, Rydb. *O. Ramalevi*, Nelson). Shrub, to 5 ft.: lvs. orbicular in outline, 3-lobed with rounded lobes, doubly crenate, usually sparingly hairy beneath or glabrous, 1–2½ in. long: corymbs dense; pedicels and calyx finely pubescent: pods 3–5, inflated, one-third longer than the calyx-lobes. June. Ill. and Mo. to Colo. and S. D.

AA. Carpels 2, turgid, tomentose.

B. Pedicels and calyx pubescent.

bracteatus, Rehd. (*Opulaster bracteatus*, Rydb. *O. Ramàleyi*, Nelson, partly). Shrub, to 6 ft.: lvs. broadly ovate in outline, rounded or subcordate at the base, 3-lobed, doubly crenate-serrate, obtuse or acute at the apex, glabrous or nearly so, 1-3 in. long; corymbs many-fl.; bracts obovate or spatulate, often foliaceous, persistent: **fls.** nearly $\frac{1}{2}$ in. across, white; pods 2, united about half. June. Colo.—Plant more compact and fls. larger than in *P. opulifolius*.

BB. Pedicels and calyx glabrous or nearly so.

monogynus, Coult. (*Opulaster monogynus*, Kuntze. *Spiræa monogyna*, Torr. *Neillia Torrèyi*, Wats.). Fig. 2937. To 3 ft. high: lvs. smaller, $\frac{3}{4}$ – $1\frac{1}{2}$ in. long, incisedly 3-5-lobed, with incisedly serrate lobes, usually glabrous: corymbs rather few-fl.; bracts lanceolate, caducous; pedicels usually only sparingly pubescent: pods 1-2. Colo. to Calif. G.F. 2:5 (adapted in Fig. 2937).

glabratus, Rehd. (*Opulaster glabratus*, Rydb.). Shrub, 2-4 ft.: lvs. orbicular-ovate, truncate or cordate at the base, 3-5-lobed, doubly crenate-serrate, obtuse or rounded at the apex, glabrous, about 1 in. long; corymbs rather small, but numerous; bracts small, caducous: fls. about $\frac{1}{2}$ in. across, white or pink; pods 2, united to above the middle. June. Colo.—Very floriferous.

P. capitatus, Kuntze (*Spiræa capitata*, Pursh. *Opulaster capitatus*, Kuntze. *S. opulifolia* var. *mollis*, Torr. & Gray). Closely allied to *O. opulifolia*. To 20 ft.: lvs. somewhat larger, with serrate, more elongated lobes, tomentose beneath: pedicels and calyx tomentose. Ore. to Calif.—*P. malvaceus*, Kuntze (*Neillia malvacea*, Greene. *Opulaster pubescens*, Rydb. *Spiræa pauciflora*, Nutt.). To 5 ft.: lvs. slightly 3-lobed, with crenately and obtusely toothed lobes, usually pubescent: corymbs rather few-fl.; pods 2-3, not inflated, tomentose, about as long as sepals. Wyo., Idaho. B.M. 7758 (as *Neillia Torrèyi*).

ALFRED REHDER.

PHYSOCHLAINA (Greek, *bladder, outer garment*, having reference to the inflated calyx). Also spelled *Physochlæna*. *Solanaceæ*. Erect, nearly glabrous herbs: lvs. petioled, subentire: infl. a terminal corymb; calyx campanulate, lobes 5, short, elongated in fr., overtopping the caps; corolla elongate, lobes 5, short-imbricate in bud; stamens attached at the middle of the tube; ovary 2-celled: fr. a 2-celled caps.—About 5 species. Cent. Asia. *P. præalta*, Hook. (*P. grandiflora*, Hook.). Perennial: sts. 2-4 ft., corymbose upward: lvs. 4-6 in. long, 3 in. broad, irregular, base cuneate or cordate on the same branch: fls. all pedicelled; calyx-lobes lanceolate; corolla tubular-funnel-shaped or sometimes shorter-funnel-shaped in wild examples, in cult. examples wider sub-campanulate: fr. a caps. $\frac{1}{2}$ in. diam. Himalaya region. B.M. 4600.

PHYSÓPTYCHIS (Greek, *bladder fold*). *Cruciferae*. Perennial plant, felty with stellate hairs: fls. yellow, short-peduncled; calyx not saccate: fr. spherical, valves net-veined; seeds without wings. Formerly included in *Vesicaria*, but now separated chiefly by the mem-

branaceous not crustaceous siliques.—One species, Persia. *P. gnaphalodes*, Boiss. (*Vesicaria gnaphalodes*, Boiss.). Half shrub: sts. simple with basal lvs.: lvs. elliptic-lanceolate, obtuse, with prominent nerves below: fr. a short silique with deciduous style, 4-celled. Persia. A small alpine plant which in general appearance resembles an aubrietia, but its foliage is grayer and its fls. are of a bright citron-yellow color. Sparingly in cult. in Eu.

PHYSÓSIPHON (Greek, *bladder tube*). *Orchidaceæ*. Tufted epiphytes: sts. in the form of creeping rhizomes, at the end 1-lvd., 1-2 sheaths below the lf., not pseudobulbous: lf. coriaceous, narrow at base: infl. an elongated raceme: fls. small, short-pedicelled, secund; sepals joined at the base in an ovoid or urceolate tube, above free, spreading; petals dwarfed in the base of the tube, fleshy, obovate-cuneate; labellum small, articulate with the base of the column, oblong-cuneate, concave, midlobe shortly exceeding the others; column below elevated, footless or produced in a short foot, clinandrium short, often obtuse, 3-lobed; anthers terminal, deciduous, pollinia 2, waxy, ovoid. About 15 species, Mex. to Brazil. *P. Loddigesti*, Lindl. Lf.-stalks 1-2 in. high, sheathed with a brown membrane: lvs. fleshy, about 4 in. high: scapes erect, 6-9 in. high, 12-15-fl., produced from the junction of the lf.-stalk and blade; scapes are produced by the same lf. in successive years: fls. small, petals and lip minute, hidden in a green, 3-sided tube formed by the connate bases of the sepals, free part of sepals orange-brown. Mex. J.H. III. 48:71. A coolhouse orchid sometimes offered in trade-lists. *P. asaroides*, Kränzl. Rhizome long and slender: sts. very short, almost none: lvs. 3-cornered, thick, lanceolate, up to $1\frac{1}{4}$ in. long, usually reddish: fls. solitary or in pairs, very shortly stalked, green-spotted and suffused with purple outside, dark purple inside; tube of sepals 1 in. long; petals and lip $1-1\frac{1}{2}$ in. long. S. Brazil. Said to be in cult. in Eu.

F. TRACY HUBBARD.

PHYSOSTEGIA (Greek, *bladder and covering*, referring to the inflated fruiting calyx). *Labiatae*. FALSE DRAGON-HEAD. Hardy herbaceous perennials, native to America, with spikes of gaping flowers of purple, rose-color, or white; useful in borders and particularly in wild-gardens.

Smooth erect herbs with slender and wand-like sts.: lvs. opposite, sessile, mostly lanceolate or oblong and usually serrate or dentate: fls. showy, pink to purple and varying to white, in separate or paniced spikes; calyx bell-shaped, swollen and remaining open in fr., membranous, 10-nerved; teeth 5, equal; corolla 2-lipped, inflated above; upper lip concave, rounded, entire or nearly so; lower lip 3-lobed, the middle lobe commonly notched; stamens 4, didynamous; anther-cells parallel.—A few species, N. Amer., mostly along stream banks and in wet grounds, but thriving under good upland garden conditions; sometimes named under *Draccephalum*. *P. austriaca* of lists is probably *Draccephalum austriacum*.

virginiàna, Benth. (*P. virginica*, Hort. *Draccephalum virginianum*, Linn.). Sts. mostly simple, to 4 ft., producing large clumps in cult.: lvs. lanceolate, oblong-lanceolate to linear-lanceolate, 3-5 in. long, finely or rather coarsely serrate, the lvs. prominent up to the infl.: fls. an inch long, ranging from purplish red through rosy pink and lilac. Que., west and south. B.M. 467. Mn. 7:81. F.R. 5:55. Gn.M. 1:121. F.E. 15:322. Var. *álba*, Hort., is a white-fl. form. R.H. 1898:336. G.W. 7, p. 458. Var. *speciosa*, Gray, is a tall form with very acutely serrate lanceolate lvs. and dense-paniced spikes. A Texan form with erect, imbricated fls. B.M. 3386 (*P. imbricata*). Var. *gigantèa*, Hort., is advertised as a giant form, 6-7 ft. tall, with large deep rose fls. *P. virginiana* is a hardy vigorous plant of the easiest

2937. *Physocarpus monogynus*.
($\times \frac{3}{2}$)

cult., blooming in midsummer and later. The clumps should be frequently divided.

denticulata, Brit. (var. *denticulata*, Gray. *Dracocephalum denticulatum*, Ait.). A lower and more slender plant with crenulate denticulate or obscurely serrate lvs. and more slender or loosely fld. spikes: lvs. few near the infl., so that the latter is as if long-peduncled. Pa. to Ill. and far south. B.M. 214.

WILHELM MILLER.

L. H. B.†

PHYSOSTÉLMA (Greek, *bladder girdle*, referring to the shape of the scales of the crown). *Asclepiadaceæ*. Twining glabrous shrubs: lvs. opposite, leathery, shining: fls. large, umbelled; sepals small, narrow; corolla cup-shaped, lobes very short; coronal processes 5, very large, ovoid-oblong, obtuse, adnate to the anthers; column tips inappendiculate: fr. long, smooth follicles; seeds comose.—About 5 species, India, Malaya.

Wállichii, Wight (*Hoya campanulata*, Blume). Lvs. 3–5 in. long, elliptic-oblong, acuminate; nerves reticulate; petiole $\frac{1}{4}$ in. long: cymes globose, 3–4 in. diam.; peduncle stout; corolla pale yellow, lobes apiculate. India, Malaya. B.M. 4545. J.H. III. 49:461. J.F. 1:70.—Cult. in Great Britain. The treatment given to hoyas is suitable for this plant.

PHYSŪRUS (Greek, *bladder and tail*; from the purse or pouch-like spur). *Orchidaceæ*. Of the type of *Goodyera* and *Anacetochilus*, and cultivated for the foliage. By late authors, the name *Erythrodus* is used for these orchids for nomenclatorial and botanical reasons.

Stem simple, erect, leafy: lvs. petiolate, ovate to lanceolate: fls. small, in a terminal raceme; petals and dorsal sepals cohering, galeate; lateral sepals free; labellum spurred, strongly concave above the entrance of the spur and abruptly contracted, middle lobe spreading or recurved; column short.—About 40 species, native of the warm regions of Asia and Amer. The American species have their lvs. mostly spotted.

querceticola, Lindl. (*Goodyera quercicola*, Chapm.). St. ascending, 6–12 in. high: lvs. ovate or oblong-ovate, thin, on slender petioles, spotted with silver-gray: spike densely fld.; sepals and petals oblong, obtuse; labellum concave, ending in a broadly ovate, acuminate and recurved point; spur pouch-like. Aug. Low shady woods, Fla. and westward. Under the new nomenclature this species becomes *Erythrodus querceticola*, Ames.

P. validus, Rolfe. Lvs. elliptic-lanceolate, about 5 in. long: scape stout, bearing an elongated dense spike about 6 in. long: fls. small, whitish. Peru.

HEINRICH HASSELBRING.

PHYTÉLEPHAS (Greek, *elephant plant*; referring to the hard white seeds which can be worked like ivory). *Palmaceæ*. Low unarmed pinnate palms.

Stems stout, erect or prostrate and rooting: lvs. terminal, elongate, pinnatisect; segms. numerous, the upper opposite, the lower alternate or fascicled, linear-lanceolate, acuminate, midrib strong: spadices peduncled, scaled, male pendulous, female erect; spathes 2, complete, elongate: fls. dioecious; male minute, perianth lacking, stamens numerous; female very large, sepals 3, petals 5–10, 2–3 in. long, rather fleshy, staminoids many, ovary subglobose: fr. a collection of 4–6 drupes, forming a large cluster.—About 15 species, S. Amer.

macrocarpa, Ruiz & Pav. **IVORY-NUT PALM**. Caudex about 6 ft. high, creeping, rooting: lvs. 15–20 ft. long, erect, beautifully arched, pinnate, rich dark green; the pinnæ very long. Colombia and Venezuela. B.M. 4913, 4914. Gn. 24, p. 468. G.M. 57:9.—This species furnishes the “vegetable ivory” of commerce. Sometimes known as “negro’s head.”

F. TRACY HUBBARD.

PHYTEŪMA (old Greek name, meaning simply “a plant,” used by Dioscorides for some nignonette-like herb). *Campanulaceæ*. **HORNED RAMPTON**. Hardy herbaceous perennials, used for borders and alpine

gardens; not much known in this country except by fanciers and those who grow rock-garden plants and alpinists.

Low or tall, with st.-lvs. alternate, and radical lvs. larger and long-petioled, sometimes very narrow and grass-like: fls. mostly blue or purplish, varying to white, usually in dense terminal heads or spikes, sometimes somewhat umbellate, the fl.-bud long and curved; corolla opening more or less with 5 very narrow segms.

2938. *Phyteuma comosum*. A tufted alpine plant growing in a crevice. ($\times \frac{1}{2}$)

(sometimes remaining closed); stamens 5, free from corolla, filaments more or less dilated at base, anthers free and distinct; styles 2–3-cleft, often protruding, the lobes very narrow: fr. a caps. crowned by the calyx-teeth, laterally dehiscent.—Species about 40, Eu. and adjacent Asia, mostly in the mountains, sometimes at great elevations.

The flowers in *phyteuma* are mostly shades of blue, more or less purple, rarely white. There are two forms of inflorescence, the globular and the long-and-narrow, the former being the more interesting. The showy feature of *P. comosum*, at first glance, seems to be a group of colored and much elongated pistils; but these pistil-like bodies are really corollas which usually show slits at their inflated base and are narrowed above into a very slender tube from which the style and stigmas are much exerted. In this species the corolla does not open, but in the others it finally splits at the top, making a spreading or wheel-shaped flower. The plants usually seed freely and may also be propagated by division, which is best performed in spring after growth begins. They thrive in ordinary garden soil in either rock-garden or border. In an account of the cultivated species, Correvon (Gn. 63, pp. 39–41, 58) distinguishes three cultural groups: (1) the mural or wall species, comprising only *P. comosum*; (2) the rock-loving species, comprising *P. Carstia*, *P. Charnelii*, *P. confusum*, *P. globulariaefolium*, *P. hemisphaericum*, *P. humile*, *P. pauciflorum*, *P. serratum*, *P. Sieberi*, *P. Scheuchzeri*; (3) the open-ground species, as *P. austriacum*, *P. betonicaefolium*, *P. canescens*, *P. Halleri*, *P. limonifolium*, *P. Michelii*, *P. orbiculare*, *P. scorzoneraefolium*, *P. spicatum*. The rock-loving species (2) require rock fissures in full sun, without damp, little soil and that only of leaf-mold and sand. The open-ground species (3) are those of woods and pastures and are easy to grow in gardens.

The botanical account following is mainly derived from DC. Prod. 7:450 and Koch, Syn., Flor. Germ., with considerable additions in descriptions from Correvon. There is likely to be some confusion in the species and the forms known in cultivation.

INDEX.

- austriacum*, 14. *globulariaefolium*, 10. *pauciflorum*, 9.
betonicaefolium, 5. *Halleri*, 7. *Scheuchzeri*, 16.
canescens, 1. *hemisphaericum*, 11. *scorzonerifolium*, 3.
Carestia, 12. *humile*, 12. *serratum*, 12.
Charnelia, 13, 15. *limonifolium*, 8. *Sieberi*, 13.
comosum, 2. *Michellii*, 4. *spicatum*, 6.
confusum, 14. *orbiculare*, 14.

A. Infl. a raceme or panicle.

1. *canescens*, Waldst. & Kit. Scabrous, grayish green: st. unbranched: lvs. sessile; lower ones ovate, crenate-serrate, narrowed at base; upper ones nearly entire: fls. blue, short-peduncled, solitary, sparse. Hungary, Caucasus.—The plant described by Correvon under this name is said to have fls. in close spikes.

AA. Infl. a compact umbel.

2. *comosum*, Linn. Fig. 2938. The only species in the genus with umbellate infl., and in which the corollas are not finally split at the apex. A decumbent unbranched glabrous plant, 3-6 in. high, native to the Alps: fls. pale lilac below, darker purple above: roots thick and fleshy, stoutly lodged in the fissures of rocks: lvs. cordate-ovate or those on the st. lanceolate, coarsely toothed: the 2-lobed styles are long-protruded. B.M. 6478. G.C. II. 14:177. Gn. 18, p. 245, copied in Gn. 28, p. 91; 44, p. 554, and R.H. 1882, p. 452. Gn. 63, p. 39. J.H. III. 52:364. G.W. 8, p. 597. G.C. II. 26:81, copied in I.H. 34:11.—Said by Correvon to demand a fissure in a wall or face of lime-rock. A handsome species.

AAA. Infl. a spike or head.

B. Fruiting spikes long and narrow, cylindrical.

c. Flowering spikes roundish or oval.

D. Stigmas 2.

3. *scorzonerifolium*, Vill. Fig. 2939. This and *P. betonicaefolium* should probably be regarded as botanical varieties of *P. Michellii*, but for clearness and for horticultural purposes they may be considered as distinct species. A native of the Alps with long-spiked fls. of sky-blue (B.M. 2066, erroneously as *P. betonicaefolium*) or purplish blue (B.M. 2271): lvs. polymorphous.

4. *Michellii*, All. This may also be distinguished from *P. scorzonerifolium* and *P. betonicaefolium* by having the calyx pilose at the middle, it being glabrous in the other two. A native of Mt. Cenis in Sardinia, with lvs. ovate-lanceolate or narrow, not cordate: color of fls. deep blue, in lengthening spikes.

DD. Stigmas 3.

5. *betonicaefolium*, Vill. Rather tall: root-lvs. cordate-lanceolate, long-stalked: bracts fewer than in *P. Michellii* and probably not reflexed: spikes lengthening toward end of season, on st. nearly 20 in. high: fls. blue. Eu. Not B.M. 2066, which is *P. scorzonerifolium*. Gn. 63, p. 57.

CC. Flowering spikes oblong or nearly so.

D. Spikes dense.

6. *spicatum*, Linn. Woodland plant: lvs. ovate-elliptical, serrate, often brown-blotched at base, the lower ones long-stalked and cordate: fls. in a close spike, white or blue, greenish at tips. Eu. B.M. 2347. Gn. 63, p. 57. G.W. 8, p. 596.

7. *Halleri*, All. Tall and stout: lvs. ovate-orbicular, doubly and coarsely serrate, long-stalked: fl.-st. 2-2½ ft.; spike ovoid-oblong, long and close subtended by 2 long drooping bracts: fls. dark violet to white. Mountains in Eu. Gn. 63, p. 58.

DD. Spikes loose.

8. *limonifolium*, Sibth. & Smith. Fig. 2939. Tall, fl.-st. 20-28 in. high and branching: fls. light blue, open, in a long narrow spike: this may be distinguished by

the st.-lvs., which are few and pass into bracts; radical lvs. lanceolate, long-petioled, sparingly toothed. Asia Minor. B.M. 2145 (as *P. stricta*). L.B.C. 7:667 (as *P. virgata*).

BB. Fruiting spikes little elongated, merely oval.

c. Number of fls. about 5.

9. *pauciflorum*, Linn. Very dwarf, said by Correvon to be the smallest and most tufted of the genus, about 3 in. high: lvs. entire or toothed at obtuse tip; root-lvs. short, obovate-lanceolate: bracts ciliate, entire or subdentate at base, never dentate at apex: fls. few in heads with ovate-orbicular bracts, violet-blue. W. Alps, Carpathians and Pyrenees. Gn. 63, p. 40.

CC. Number of fls. about 12.

10. *globulariaefolium*, Sternb. & Hoppe. Probably a variety of *P. pauciflorum* with larger sts. and lvs. widened in the upper part and toothed, and by more globular heads: root-lvs. 2-4 lines longer and thrice as wide, and the bracts always entire at the base: fls. violet. Austrian Alps.

2939. *Phyteuma limonifolium* and *P. scorzonerifolium*, showing loose-spiked and dense-spiked forms of inflorescence.

11. *hemisphaericum*, Linn. Small plant with grass-like foliage, forming large tufts: lvs. erect; root-lvs. subentire, linear or lanceolate-linear, much or little shorter than the st.: bracts ciliate, subentire, ovate-lanceolate: fls. blue, white or yellowish. Granitic Alps.

12. *humile*, Schleich. Root-lvs. linear-lanceolate, narrowed at the base, upper ones remotely denticulate, larger than those of *P. hemisphaericum*: bracts narrowly lanceolate from an ovate base, sharply toothed: fls.

violet-blue, in globular heads. High Alps.—*P. Caréstix*, Birolì, is a thick-set form of *P. humile*. Probably *P. serratum* is also a form of this species with larger st., somewhat wider lvs., and calyx glabrous rather than minutely ciliate. Gn. 28:90; 63, p. 40.

13. *Sieberi*, Spreng. (*P. Charméliei*, Sieb., not Vill.). Lvs. cordate, ovate or ovate-lanceolate to ovate-orbicular, crenate: bracts ovate, acuminate, sharply serrate: fls. deep violet-blue, in globular heads. S. Alps and Apennines.

ccc. Number of fls. 15 or more.

14. *orbiculäre*, Linn. (*P. confusum*, Kerner. *P. austriacum*, Beck). Rootstock mostly thick, the sts. simple and usually erect, $\frac{1}{2}$ –2 ft. tall: lvs. crenate; root-lvs. cordate or ovate; upper st.-lvs. linear: bracts subserrate, spreading or reflexed: fls. purple. Eu. B.M. 1466 (as *P. cordata*). L.B.C. 2:122.—A very variable species, and widely distributed, from England to mountain pastures on the continent. Correyon keeps *P. austriacum* distinct, the basal lvs. having blades longer than petioles, upper lvs. ovate-lanceolate, and specially by the erect fl.-bracts; also *P. confusum*, from granitic rocks of the Tyrol, which seems from his description to be a very different plant, with long and grass-like lvs. and deep violet fls.

15. *Charméliei*, Vill., not Sieb. Rootstock thick and brittle: sts. 6–12 in.: lvs. soft and coarsely serrate: bracts linear-lanceolate: fls. dark blue, in globular heads. Probably a botanical variety of *P. Scheuchzeri*. Alps. Here probably belongs the cut-lvd. *P. comosum* in Gn. 19, p. 419; 44, p. 554; and *P. orbiculäre*, Gn. 28, p. 90.

16. *Scheuchzeri*, All. Sts. slender and flexible, 4–16 in. tall: lvs. ovate-elliptical, serrate, the upper ones long and narrow: bracts 18–24 lines long, reflexed or spreading: fls. deep violet-blue, in rounded heads, the bracts exceeding the head. S. Eu., in mountains. B.M. 1797. Gn. 63, p. 40.

WILHELM MILLER.

L. H. B.†

PHYTOLACCA (a hybrid name: Greek, *phytos*, plant, and French *lac*, or Italian *lacca*, lake; referring to the crimson berries). *Phytolaccaceæ*. Ornamental herbs and woody plants; some of them yield edible parts of minor value.

Shrubs, herbs, or trees, sometimes climbers, with angled or subterete branches, glabrous or nearly so: lvs. alternate, sessile or mostly petiolate, acute or obtuse, entire; stipules none: fls. small, borne in erect or nodding racemes on spikes which are at first terminal but by further growth of the st. may come opposite the lvs.; calyx of 4 or 5 persistent rounded sepals; stamens about 5–30; ovary of 5–16 distinct or connate carpels: fr. a fleshy berry; seeds 1 in each cell.—Twenty-six species as defined by Walter in Engler's *Das Pflanzenreich*, hft. 39 (IV. 83), published in 1909, distributed in tropical and subtropical regions, mostly in Amer., and a few in Asia and Afr., one species extending to Canada. They are plants of simple requirements in the regions where they grow, and are prop. readily by seeds. *P. dioica* is a very useful tree for ornament and shade in S. Calif. The common pokeweed (*P. americana*) is a familiar wild plant in E. N. Amer.; it is a plant of good habit, vigorous growth, and ornamental berries, and is sometimes placed in back borders and wild-gardens. Related genera in cult. are *Ercilla*, *Rivina*, *Agdestis*.

A. Stamens and carpels 10.

americana, Linn. (*P. decandra*, Linn.). POKE. SCOKE. GARGET. Tall stout bushy perennial herb, reaching 10–12 ft. high, the sts. soft or semi-succulent and smooth, glaucous, and the maturer parts purple-tinged: lvs. oval-oblong or oblong-lanceolate, gradually narrowed both ways, acuminate the petiole more or less mar-

gined: fls. purplish or greenish white, in peduncled simple racemes and borne on stout bracted pedicels; ovary 10-carpelled and green, ripening into a wine-purple berry. Maine through Ont. to Minn., and far southward; naturalized in Eu.; often a weed, particularly in clearings and new lands. B.M. 931. Gn. 21, p. 179. G. 7:667. Mn. 1, p. 53.—A robust plant with heavy odor, but of good habit and clean. This species, the common pokeberry, is offered by dealers in native plants and its young asparagus-like shoots are sometimes used as a pot-herb. Its flattish berries yield a crimson juice of a very distinct hue, but it has never been fixed for dyeing purposes. Children sometimes make red ink from the berries for amusement. The berries have been used to give color to pale wines, but its use for this purpose is injurious and in Portugal has been prohibited by royal decree. The roots are emetic, purgative, and somewhat narcotic. The word "poke" is supposed to come from the American Indian word *poacan*, which apparently referred to any plant yielding a red or yellow dye, as pokeweed or bloodroot. In President Polk's campaign his followers wore lvs. of pokeweed. In collecting young shoots for greens, care must be taken not to include any portion of the root, as this would give a bitter taste and might cause serious illness, as the roots contain powerful drastic principles. Small pieces of the root eaten by mistake for horse-radish or turnip are reported to have caused serious and in some instances fatal cases of poisoning. The seeds are also poisonous. Directions are given in some of the older writings for the cult. of poke for the young shoots, which are eaten early in the season as a substitute for asparagus; but the wealth of other pot-herbs renders this plant unnecessary. It may be increased by seeds or by division of the thick roots. A variegated form once cult. for ornament is shown in R.H. 1887, p. 16, the lvs. light green above often shaded rose and more or less margined white, beneath pale rose to violet.

AA. Stamens and carpels less than 10, usually 8.

esculenta, Van Houtte (*Pircunia esculenta*, Moq. *Phytolacca Kaempferi*, Gray. *P. pekinensis*, Hance). Somewhat woody, suberect, the sts. thick, green and glabrous: lvs. short-petioled, broad-elliptic or ovate, the apex somewhat acute or blunt: infl. suberect, loosely racemose, not surpassing the lvs., the peduncle and rachis glabrous: fls. pedicellate; calyx white, the parts rounded; stamens commonly 8, with white filaments and rose-colored anthers; style recurved: fr. with 8 free carpels. China, Japan.—Cult. for the edible lvs. This name is catalogued in England as "American grape."

acindosa, Roxbg. Much like the last: peduncles and rachis scabrous: filaments and anthers white; style suberect; calyx-parts green at middle, white on margin, apex acute: lvs. ovate-oblong, acuminate at apex. China and Japan; spontaneous in India and said to be cult. for its lvs. which are edible when cooked.

AAA. Stamens 20–30; carpels 7–10: fls. diœcious.

dioica, Linn. (*Pircunia dioica*, Moq. *Phytolacca populifolia*, Salisb. *P. arborea*, Hort.). Evergreen tree, attaining great thickness of trunk and spread of top: branchlets glabrous: lvs. slender-petioled, glabrous, elliptic or ovate, mostly broadly acute at apex, the mid-nerve extending at the tip: infl. racemose, scarcely surpassing the lvs., suberect or pendulous: male fls. with 20–30 stamens, and calyx-parts elliptic and obtuse, white-spotted; female fls. with about 10 staminodia, the calyx parts broad, the ovary globose and 7–10-carpelled: fr. berry-like, the carpels connate at base and free at top. S. Amer., the "umbú" and "bella sombra" of Spanish-speaking people.—This species was intro. into Santa Barbara some 40 years ago, and is now well distributed in S. Calif.; there are trees with spread of top of 50 ft. and trunk 6 ft. diam., with buttresses 2 ft. high. It is a tree of astonishingly rapid growth, soon

making a good shade. In a recent freeze, it is reported that trees have lost their lvs, but the growth remained uninjured.

L. H. B.†

PIARÁNTHUS in part: *Caralluma*.

PICEA (ancient Latin name derived from *pix*, pitch). *Pináceæ*. SPRUCE. Ornamental trees, grown for their evergreen foliage and regular pyramidal habit; many species are valuable timber trees.

Evergreen trees with usually whorled spreading branches: lvs. usually 4-angled with white lines formed by numerous stomata arranged in rows and on all 4 sides, or compressed and stomatiferous only on the upper or ventral side which, on the lateral branchlets, by twisting of the lf.-stalk appears to be the lower one, sessile and jointed at the base to a short stalk projected from a prominent cushion called a pulvinus: fls. monocious, catkin-like, terminal or axillary; the staminate yellow or red, consisting of numerous spirally arranged anthers with the connective enlarged at the apex and scale-like; the pistillate greenish or purple, consisting of spirally arranged scales each subtended at the base by a small bract and bearing 2 ovules at the inner side: cones pendulous or spreading, with persistent scales not separating from the axis after shedding the seeds, which are provided with a large and thin obovate or oblong wing.—Thirty-eight species in the colder and temperate climates of the northern hemisphere from the arctic circle to the high mountains of the temperate regions. They are all mentioned below and all of them except 4 are in cult. The names *Picea* and *Abies* are often exactly transposed by horticulturists and others.

The spruces are usually tall trees of pyramidal habit, sometimes dwarfed in horticultural varieties or in alpine forms, with spreading usually whorled branches clothed densely with acicular spirally arranged leaves. The catkin-like flowers appear in spring and are often very conspicuous by their bright red color. These are followed by usually pendent cones, green or purple before ripening and light to dark brown at maturity. The spruces are not only highly ornamental, but also very valuable forest trees, and as inhabitants of cooler climates they are especially adapted for cultivation in northern regions. Almost all are hardy North, except *P. sitchensis*, *P. Smithiana* and *P. spinulosa*, but they do not resist heat and drought well; some, however, as *P. pungens*, *P. canadensis*, *P. Omorika*, *P. orientalis*, *P. excelsa*, and some of the recently introduced Chinese species grow better in a drier climate than most others. For ornamental park planting the spruces belong to the most valuable evergreens on account of the symmetrical habit and rapid growth of most species. Only a few, like *P. orientalis*, *P. obovata*, *P. Omorika*, and *P. polita*, are of slower growth and therefore well suited for smaller parks and gardens; and so are the numerous horticultural forms, which are mostly dwarf and slow-growing and sometimes more interesting and curious than beautiful. The spruces are often planted as shelters and windbreaks, and also used for hedges, especially *P. excelsa*, which makes a very dense and durable hedge when regularly trimmed. *P. polita* is also recommended as a good hedge plant and seems well adapted, with its rigid spiny leaves. The spruces thrive best in moderately moist sandy loam, but will grow in almost any kind of soil provided it contains enough moisture; wet and dry soils are equally unfavorable. Slopes of northern aspect are well suited for spruces, and they thrive better in shady positions than most other conifers. As the roots mostly spread horizontally near the surface, the spruces will grow in shallow soil and are easily transplanted even as rather large plants; they may be moved with success at any time of the year except when the young shoots are growing, but if possible avoid transplanting shortly before dry weather is expected to set in.

Spruces are propagated by seeds, which ripen in fall and are usually kept dry and cool during the winter and sown in spring outdoors in prepared beds or in frames or boxes. The young seedlings should be shaded and watered in dry weather and may remain a year or two before being transplanted in nursery rows when not sown too thickly. Varieties and rarer kinds are often increased by layers or by grafting on seedling stock of *P. excelsa*. *P. canadensis* is used for forms of this species and for *P. mariana* and *P. rubra*. Veneer-grafting in spring or August in the greenhouse is usually employed; less commonly cleft-grafting with half-hardened wood. The dwarf forms grow readily from cuttings under glass in August or fall and given slight bottom heat in early spring; also most other forms and species, especially those with thinner and finer branches, can be raised from cuttings.

The spruces are important timber trees. The soft and light straight-grained wood is much used for construction, the interior finish of houses and for fuel, also for ship-building; but it is not durable in the ground. The bark of some species is used for tanning leather, and the resinous exudations are sometimes employed in medicine. From the red and black spruce, spruce beer is made by boiling the branches with honey. Spruces are often known in nurseries, especially in this country, under the name of *Abies*.

The grafting of piceas. (E. P. Drew.)

In the writer's experience, *P. canadensis* is a good stock on which to graft the finer varieties of spruce or those having four-sided leaves. Pot the stock the last of August, keep in shaded frame, syringe till danger of wilting is over and harden gradually. Be careful not to keep the earth in the pots too wet, as roots are liable to rot. Place the stocks in greenhouse after light frosts, and graft as soon as roots have started—about last of January generally. Do not wait until buds have made much growth, for then the sap will be running strongly to the upper buds, leaving the cion to remain dormant. When stock and cion are of same size, the veneer-graft may be used. In large stocks, use slit- or side-graft. Be sure that the knife is sharp enough to shave dry wood. Cut the cion in elongated wedge-shape; place it in the cleft by twisting the stock with left hand, fitting the cion exactly with the right. Be careful to wax well, as a

2940. Cone of Norway spruce. — *Picea excelsa*. ($\times \frac{1}{2}$)

hole the size of a pin left on the cut surface will be fatal to the cion. Place the grafted plants in a close frame until the cion is well started. Syringe from two to three times a day, shading when too hot. Give air gradually until well hardened. Do not cut back the stock for one year, as the cion may make second growth and winter-kill. If cion should die, do not use the stock again until after a year's rest, as two consecutive pottings will usually ruin the plant; this holds good only with *Tsuga* and *P. canadensis*. The above method can be used with equal success on *Pinus*, *Abies*, *Juniperus*, and other evergreens propagated by grafting.

Ornamental value of spruces. (Thomas H. Douglas.)

The piceas embrace some of the most useful as well as ornamental trees of the conifer family. They cover a great variety of forms, from the stiff-branched sturdy and rugged *P. pungens* to the lithe graceful and drooping *P. Breweriana*. The American species comprise

P. mariana, *P. canadensis*, *P. rubra*, *P. pungens*, *P. Engelmannii*, *P. Breweriana*, and *P. sitchensis*. The grand and towering Douglas spruce and the graceful hemlock spruce, so called, are not true spruces and will not be noticed in this article.

The white spruce, *Picea canadensis*, is a native of the northern parts of America and is justly thought to be one of our best conifers, a compact and upright grower of great longevity; trees growing at Waukegan, Illinois, of mature age, are well branched at the bottom, retain their pyramidal form, and annually make an upward growth. It is the most aromatic of the piceas; in fact, this odor is often used to identify it while young from the Norway spruce or Engelmann's spruce. It grows on a great variety of soils, bears crowding well and also will stand severe pruning; hence it is used for windbreaks and hedges. Seedlings vary considerably in color, some of them fairly rivaling the blue form of the *P. pungens*. This tree, being a native of a cold climate, is subject to the ravages of the red-spider in a warm

from a light silvery hue in some specimens to a dark blue, almost purple in others. In some specimens the branches are in distinct and regular whorls, resembling *Araucaria excelsa*. Undoubtedly the oldest and finest specimens of this grand tree are found on the former grounds of the late Robert Douglas, at Waukegan, Illinois. These trees are now 35 to 40 feet high and show no signs of weakness anywhere, being one mass of foliage from the ground upward. The green form of *P. pungens* is an excellent tree, but is not so much appreciated by planters and lovers of trees as it should be, as it is always compared to its more striking variety, the blue spruce. There is a fine specimen growing on the above grounds, even larger than the blue form, which does not suffer in comparison with its near neighbors, *Abies concolor*, *A. Fraseri*, *Picea Engelmannii*, *Tsuga canadensis* or hemlock spruce, *Pseudotsuga Douglasii* or Douglas spruce, and *Pinus Strobus*, all large and fine specimens, equal to any in the Middle West.

Picea mariana, or black spruce, is undoubtedly the poorest tree of the genus from a landscape gardener's point of view. It has very short needles and is greatly disfigured by its cones, which hang on for several years. It begins seeding when very young and is an exceedingly slow grower. Some good specimens of it are found, however, in the East, but in very restricted localities. *P. rubra*, long thought to be a variety of the preceding, is a much better tree in every respect, resembling *P. excelsa* in color and form. It seems to be a short-lived tree, especially in the West. This tree is undoubtedly the least known of the American piceas. *P. sitchensis* of the Pacific Coast strongly resembles *P. pungens*; in fact, when the latter was first introduced it was thought to be a variety of *P. sitchensis*. It has much finer branches and needles than *P. pungens*, varies in coloring as much as the latter, and, where hardy, makes a very fine tree. Unfortunately it is not hardy in any of the northern states. Unlike *P. pungens*, it will not stand close planting, as the needles fall off badly where the branches are rubbed together by the wind or strike other objects.

Without doubt the most graceful and elegant picea is *P. Breweriana*, or weeping spruce, a native of the Siskiyou and Coast Ranges of mountains in northern California and Oregon. It has the true spruce form, tall and symmetrical, with horizontal branches and a beautiful dark green color. In its general features it resembles a well-grown specimen of the Norway spruce, but its distinguishing beauty is in the long pliant pendulous branchlets which hang straight down from the branches to a length of 6 to 8 feet and no larger around than a lead pencil. It has a stately grace in calm weather, but its characteristic impressiveness is seen only when the long flexible branches are undulating in a light breeze or streaming before a gale. The bark is smooth and reddish in color, adding to its beauty where glimpses of it can be seen through the green foliage. It grows only at high elevations in its native habitat and on the northern slope of the mountains where the annual fall of snow is 15 to 25 feet. The cones are from 2½ to 3½ inches long, of a purplish color, and as they grow only on the tips of the branches they add greatly to its beauty. Unfortunately this beautiful tree has not proved satisfactory. Out of over 300,000 seedlings raised in 1893, only one plant is now alive; it is growing on the Douglas grounds and is scarcely 5 feet tall, having cost over \$100 a

2941. Shedding of the leaves of Norway spruce.—*Picea Excelsa*.

The picture shows the extremities of a limb that is eight years old. The part between the tip and A is last season's growth; between A and B it is two years old; and beyond B is a part that grew three seasons ago. The section beyond C is six years old; from C to D is seven years of age. The four years' growth of this limb not shown in the drawing was as densely covered with foliage as is the part shown in the upper figure; but there are not many leaves between C and D (seven years old) and none on the eight-year-old wood (except those on the branchlets, and these are younger). This shows that the leaves persisted six or seven years.

climate and should not be planted south of Philadelphia or St. Louis. There is a variety of *P. canadensis* found in the Black Hills that stands extreme drought better than the northern form and is largely planted on the dry prairies of Nebraska and the Dakotas. It does not, however, do so well in northern Illinois or farther east as the northern variety.

Picea Engelmannii, one of the gems of Colorado, resembles *P. canadensis* more than it does its near neighbor, *P. pungens*, being of finer foliage and not so stiff-branched as the latter. It is one of the few conifers that will stand the extreme cold of Petrograd, Russia, but on our western prairies it soon loses its lower branches, as it seems to be unable to withstand the hot and drying winds of that section in late summer and early autumn. In the eastern states, however, it does not have this fault, as the cooler and more humid air seems better to agree with it.

Another Colorado conifer, *P. pungens* (the blue form being called by some the "queen of the piceas"), is a striking and noble tree, seeming to be hardy wherever tested and on all varieties of soil. Strong, sturdy, and upright in growth, its form alone would make it a striking figure in any landscape. Its beautiful color varies

LXXXVIII. *Picea canadensis* (or *P. alba*).—A golden variety.

foot, and this is doubtless one of the largest specimens in cultivation.

Of the foreign piceas, *P. excelsa* is most popular; in fact is the best known and most largely planted of any of the genus. It makes a large fine-looking tree, grows in a great variety of soils, is hardy throughout most of North America, is the most rapid grower of any of the piceas, and stands close planting very well. It is used more than any other tree for windbreaks and shelter-belts. It bears pruning well. Hedges of this species and *P. canadensis* that have been planted more than forty years are growing on the Douglas grounds that are now 8 feet high, and 9½ feet across the base. One fine specimen tree on these grounds measures about 63 feet high and 64 feet from tip to tip of its lower branches. Other foreign species, but not so well known nor so thoroughly tested as the preceding, are *P. obovata*, a close compact-growing tree dark green in color. *P. Smithiana* or *P. Morinda* is one of the handsomest of the piceas, but is not hardy in the northern states, plants from seed collected at an elevation of 8,000 feet on the Himalaya Mountains not proving hardy. Fine specimens of this tree are found in California, where it is justly prized. *P. Omorika* from southeastern Europe is one of the best of the hardy foreign piceas; it does well in the eastern states and forms a narrow pyramid with slender branches clothed with dark glossy foliage. There are several species of *Picea* from China and Japan that will doubtless prove hardy in the eastern states. Of these *P. jezoensis* var. *hondoensis* has proved one of the best in the eastern states; also *P. bicolor*, which forms a handsome pyramidal tree of rapid growth with dark green foliage, has proved perfectly hardy. All piceas will stand the pruning-knife, but this should be used not later than July 1 in the northern states and earlier farther south. They are propagated from seed the same as larix; and their varieties, of which there are a great number, are either grafted or raised from cuttings over bottom heat.

INDEX.

KEY TO THE SPECIES.

- A. Lvs. quadrangular, all 4 sides with stomata.
- B. Scales of cone obovate or orbicular, rounded, closely appressed before ripening.
- C. Cones 2½–6 in. long.
 - D. Length of lvs. ¾–2 in.: young branchlets glabrous, more or less pendulous.

- E. Lvs. spreading, sometimes 2 in. long: winter buds acute.
- EE. Lvs. pointing forward, not over 1½ in. long: winter buds obtuse..... 1. *Smithiana*
- DD. Length of lvs. ½–1 in.
 - E. Lvs. spreading, rigid, sharply pointed: branchlets glabrous, pale yellow..... 2. *Schrenkiana*
 - EE. Lvs. pointing forward.
 - F. Young branchlets pale yellowish gray, pubescent: petioles very prominent, often recurved..... 3. *polita*
 - FF. Young branchlets brown, puberulous or glabrous.
 - G. Cones 4–6 in. long, or shorter in some varieties with stiff scales: branchlets glabrous or sparingly hairy..... 4. *asperata*
 - GG. Cones less than 4 in. long, with flexible scales: branchlets puberulous..... 5. *excelsa*
 - DDD. Length of lvs. less than ½ in.: lvs. bright green, lustrous, obtusish: branchlets pubescent, light brown..... 6. *obovata*
 - CC. Cones ¾–2 in. long.
 - D. Young branchlets pubescent.
 - E. Color of lvs. dark green, lustrous: cones ovate-oblong, very short-stalked, deciduous; scales entire or denticulate..... 7. *orientalis*
 - EE. Color of lvs. dull, usually bluish green: cones ovate, distinctly stalked, persistent for many years; scales erose or dentate..... 8. *rubra*
 - DD. Young branchlets glabrous, light brownish yellow..... 9. *mariana*
 - BB. Scales of cone oblong or rhomboidal, erose at the margin and usually striate and undulate, thin, very loosely appressed or slightly spreading.
 - C. Winter buds with appressed scales: branchlets pubescent: lvs. pointing forward, rather flexible..... 10. *canadensis*
 - CC. Winter buds with loose scales revolute at the apex: branchlets glabrous: lvs. spreading, rigid..... 11. *Engelmannii*
 - AA. Lvs. more or less compressed, with 2 white lines above, green below or sometimes with few stomata.
 - B. Cone-scales rhomboidal, erose-denticulate, flexible, loosely appressed.
 - C. Cones brown at maturity: lvs. flattened.
 - D. Bracts visible between the scales of the cone: lvs. rigid, pungent: mature branchlets orange-brown: winter buds ovate..... 12. *pungens*
 - DD. Bracts not visible: lvs. not pungent: mature branchlets greenish to light reddish brown: winter buds conical..... 13. *sitchensis*
 - CC. Cones purple: branchlets orange-yellow, setose: lvs. quadrangular, somewhat compressed..... 14. *jezoensis*
 - BB. Cone-scales orbicular or obovate, closely appressed before maturity.
 - C. Branchlets glabrous, only leading shoot more or less hairy or all pubescent: lvs. quadrangular, somewhat compressed..... 15. *purpurea*
 - CC. Branchlets always pubescent: lvs. much compressed.
 - D. Lvs. keeled, ½–½ in. long: branchlets short..... 16. *bicolor*
 - DD. Lvs. nearly rounded on both sides, ½–1 in. long: branchlets long, drooping..... 17. *Omorika*

Section I. EUPICEA, Willk.

Lvs. quadrangular, with stomata on all 4 sides: scales of cone closely appressed before maturity, broad and entire or nearly so.

1. *Smithiana*, Boiss. (*P. Morinda*, Link. *P. Khàt-row*, Carr.). Tree, to 150 ft., with wide-spreading branches and slender pendulous branchlets: lvs. crowded, usually thicker than broad, acute, bright or dark green, $\frac{3}{4}$ –2 in. long: pistillate fls. purple: cones 5–7 in. long, dark brown and glossy; scales suborbicular, with entire margin, firm. Himalayas. G.C. II. 24:393; III. 35:325; 38:395. Gn. 19, p. 359; 35, p. 599; 39, p. 72. C.L.A. 7:364. F.E. 16:705.—One of the most graceful spruces; hardly as far north as N. Y. The young growth starts very early and is liable to be injured by frost in spring, especially when planted in warm and damp situations.

2. *Schrenkiana*, Fisch. & Mey. (*P. obovata* var. *Schrenkiana*, Carr.). Tall pyramidal tree, with pendulous branchlets, somewhat similar to *P. excelsa*: lvs. equally 4-sided, acute, somewhat dull green, $\frac{3}{4}$ –1½ in. long, on young plants often slightly shorter: cones cylindric-ovate, 3–4 in. long; scales with entire margin. Siberia to N. China.—Similar in habit to the preceding species but branchlets not so long and lvs. shorter. A very desirable and hardy spruce. Var. *globosa*, Schelle. About 6 ft. high, globose in shape.

3. *polita*, Carr. (*P. Torano*, Koehne. *P. bicolor*, Hort., not Maxim.). Tree, to 90 ft., forming a dense, broad pyramid, with rigid stout branches when young, older trees with the habit of *P. excelsa*, with somewhat pendulous branches: young branches thick, glabrous, yellowish brown: lvs. rigid, thicker than broad, often falcate, shining dark green, $\frac{1}{2}$ –1 in. long: pistillate fls. green, staminate yellowish: cone oblong, 4–5 in. long, brown, glossy; scales with finely denticulate margin. Japan. S.Z. 2:111. G.C. II. 13:233; III. 21:251. Gn. 13, p. 239. S.I.F. 2:2.—One of the most distinct spruces; of very striking appearance with its rigid spiny lvs. spreading in all directions from the stout branches, but usually of rather irregular habit.

4. *asperata*, Mast. Tree, to 100 ft., with grayish brown bark peeling off in thin flakes: branchlets pale yellowish gray, pubescent: lf.-cushions with often spreading or recurved petioles: lvs. quadrangular, curved, $\frac{1}{2}$ in. long or slightly longer, acute or acutish and beveled at the apex: cones cylindric-oblong, $\frac{3}{4}$ –4 in. long, fawn-gray when ripe, finally changing to

2942. *Picea mariana* ($\times \frac{1}{2}$). No. 9.

chestnut-brown; cone-scales usually rounded and entire at the apex. W. China.—A valuable timber tree. Var. *notabilis*, Rehd. & Wilson. Lvs. $\frac{1}{2}$ –¾ in. long: cones 3½–5 in. long; scales rhombic-ovate, narrowed toward the apex. Var. *ponderosa*, Rehd. & Wilson. Bark thicker, brownish gray: branchlets nearly glabrous, yellowish: cones 5–6 in. long.

5. *excelsa*, Link (*P. Abies*, Karst. *P. rubra*, A. Dietr. *Pinus Abies*, Linn. *Pinus Picea*, Dur.). NORWAY SPRUCE. Figs. 2940, 2941. Tree, to 150 ft., with spreading branches and usually pendulous branchlets: bark reddish brown: young branches brown, glabrous or pubescent: lvs. quadrangular, acute, dark green and usually shining, $\frac{1}{2}$ –1 in. long: staminate and pistillate

fls. bright purple: cones cylindric-oblong, 4–7 in. long, light brown; scales obovate, with erose-denticulate margin. N. and Cent. Eu. Em. 1:102. Mn. 4, p. 185; 6, p. 85. F.E. 15:350, pl. 50. H.W. 1:1, pp. 54–61. C.L.A. 11:311. G.W. 2, p. 535; 6, p. 322.—Though *P. Abies* is the correct name for this species according to the rules of priority, we have retained here the name *P. excelsa*, because *Picea Abies* and *Abies Picea* might be easily confused and are certainly somewhat perplexing. It seems therefore advisable to take the next oldest names which are *Picea excelsa* for the Norway spruce and *Abies alba*, Mill., for the silver fir.—This tree is extensively planted as an ornamental tree in the northern and eastern states; it is of rapid growth and is a handsome tree, with its graceful habit and dark green dense foliage, but, like many spruces and firs, loses much of its beauty when it grows old, and usually after 30 years it becomes thin and ragged in the top. It is one of the best conifers to plant for shelters and windbreaks. The Norway spruce is very variable, and a great number of garden forms are in cult. Some of the more important are the following:

Pendulous or sparingly branched forms of P. excelsa: Var. *virgata*, Casp. (var. *denudata*, Carr.). Sparingly branched, with long and slender branches destitute of branchlets, spreading, usually the lower ones pendulous and the upper ones ascending. R. H. 1854, p. 102. G.W. 3, p. 523; 6, p. 607. M.D.G. 1894:31. H.W. 1, p. 63. *P. excelsa* var. *elata*, Hort., is probably a seedling of this variety and an intermediate form varying toward the type. Var. *monströsa*, Beissn. (var. *monocaulis*, Nördl. *Abies excelsa monströsa*, Loud.), is an extreme form of the preceding and is destitute of all branches; it consists only of a single st. clothed with thick rigid lvs. Var. *viminialis*, Casp. Branches in remote whorls, almost horizontal, with very long and slender branchlets without or with very few lateral branchlets. G.W. 3, p. 433; 9, p. 411. M.D.G. 1902:257; 1906:557. Gt. 38, p. 136. H.W. 1, p. 64. Var. *péndula*, Jacq. & Herincq (var. *reflexa*, Carr.). With pendulous branches and branchlets; whorls of branches often irregular. Gt. 48, pp. 618, 619; 50, p. 315; 52, p. 434. G.W. 6, p. 213. R.H. 1890, p. 259. Var. *inversa*, Beissn. (*Abies excelsa inversa*, Gord.). Similar to the preceding, but branches more closely appressed to the st., more densely branched, with thick lustrous lvs. Gng. 6:100. F.E. 22:765. G.M. 54:976. Gn.M. 2:24. G.C. III. 22:369; 29:263. Gt. 50, p. 317. B.H. 10, p. 300.

Columnar forms: Var. *pyramidalis*, Carr. (var. *erecta*, Schröter). With branches ascending at an acute angle, forming a narrow, nearly columnar pyramid. Var. *columnaris*, Carr. With very short, horizontal much ramified branches, forming a narrow column. M.D. 1911, p. 260. Var. *cupressina*, Thomas, is similar. M.D. 1907, p. 252.

Dwarf and dense, pyramidal, subglobose or prostrate forms: Var. *cònica*, Carr. A dense conical pyramid with ascending branches and slender branchlets: lvs. thin and pointed. Var. *Remontii*, Beissn. A dense ovate or pyramidal form with short and dense branches. G.M. 54:222. F.E. 16:491. M.D.G. 1906:557. Var. *Clanbrasiliana*, Carr. (*Abies excelsa Clanbrasiliana*, Loud.). A compact roundish or broadly conical form with short and crowded branches: lvs. short and thick. M.D. 1906:222. G.M. 57:634. Var. *compácta*, Beissn. A subglobose dense form with slender branchlets and acute short lvs. F.E. 16:585, pl. 65. Var. *Gregoryana*, Beissn. (*Abies excelsa* var. *Gregoryana*, Gord.). A compact subglobose form densely branched, with short thickish pungent lvs. Var. *pygmæa*, Carr. A very dense, small, pyramidal form with ascending branches and bright green lvs. Gn.M. 2:23. Var. *nana*, Carr. A depressed subglobose form with dense horizontally spreading branches and short sometimes monstrous branchlets. Var. *tabuliformis*, Carr. A low flat form

with horizontally spreading branches. Var. *procumbens*, Carr. A prostrate form with numerous short branchlets and dense short and pointed lvs. Var. *dumosa*, Carr. Similar to the preceding, but less densely branched and lvs. more distant. Var. *repens*, Simon-Louis. A creeping form.

Low, irregularly branched monstrous forms: Var. *Bárryi*, Beissn. With vigorous thick branches and few short branchlets, dark green. Var. *Ellwangeriana*, Beissn. A broad growing form with crowded slender branchlets and small and thin, acute lvs. Var. *capitata*, Carr. Dwarf bushy form, with numerous short branchlets in dense heads at the end of the branches. R.H. 1889, p. 393. Var. *Máxwellii*, Beissn. A low flat dense form, the young branches brown, often with short fascicled branchlets: lvs. bright green, rigid, pointed.

Variegated forms: Var. *finedonensis*, Beissn. (*Abies excelsa finedonensis*, Gord.). Lvs. pale yellow at first, becoming bronzy brown and finally green. Var. *argenteo-spicata*, Hesse. Young shoots whitish. Var. *aurea*, Carr. Lvs. golden yellow on the exposed side; does best in a partly shaded situation. Var. *mutabilis*, Carr. Young shoots yellow, changing soon to green. G.W. 3, p. 556.

The most important of the geographical forms are: Var. *fénica*, Rupr. Similar to *P. obovata*: cones not more than 3 in. long. N. Eu. and N. Asia. Var. *medióxima*, Nyland. Small tree or sometimes shrubby: lvs. thickish, shorter, lustrous, green: cones to 3 in. long. Resembles somewhat *P. orientalis*. N. Eu. Var. *alpéstris*, Brügg. Slow-growing compact tree: young branchlets velutinous: lvs. shorter, usually obtusish, dull yellowish or grayish green: cones 3-5 in. long. Resembles in habit and foliage somewhat *P. canadensis*. In the Alps at high altitudes.—There are two forms of the common Norway spruce differing in the color of the young cones: Var. *chlorocarpa*, Purk. Young cones green: lvs. obtusish, more appressed; leafing later. Var. *erythrocarpa*, Purk. Young cones violet-purple: lvs. more spreading, pointed; leafing earlier.

6. *obovata*, Ledeb. (*P. excelsa* var. *obovata*, Koch). Tree, to 100 ft., similar in habit to the following, with somewhat pendulous branchlets: young branches brown, glabrous or slightly pubescent: lvs. quadrangular, acute, dull or bluish green, $\frac{1}{2}$ – $\frac{3}{4}$ in. long: pistillate fls. purple: cone oblong-ovate, light brown, about $2\frac{1}{2}$ in. long; scales with entire margin. N. Eu. to Kamchatka and Manchuria. Gn. 20, p. 91. R.H. 1894, p. 274. Mn. 5, p. 189.—Of slower growth than *P. excelsa* and more graceful.

7. *orientalis*, Carr. Tree, to 120 ft., with ascending and spreading branches and somewhat pendulous branchlets: young branches brown, pubescent: lvs. thick, obtuse, dark green and shining, crowded and more or less appressed to the branches: fls. carmine: cone cylindric-ovate, $2\frac{1}{2}$ – $3\frac{1}{2}$ in. long, less than 1 in. thick; scales orbicular, entire at the margin. W. Asia, Caucasus. G.C. II. 21:308; 25:333; III. 3:754. A.G. 19:649. Mn. 5, p. 189. V. 20:185. C.L.A. 11:311. Gn.M. 2:25. G.W. 16, p. 261.—A very graceful spruce with dark, glossy foliage; of slow growth and therefore valuable for smaller gardens. It holds its lower limbs for many years. Var. *nana*, Carr. Low form of broadly pyramidal habit, with wide-spreading branches. Var. *aureo-spicata*, Beissn. Young shoots yellow. Var. *nütans*, Niemetz. With graceful hanging branches. Var. *semi-virgata*, Schwerin. Branches with few lateral branchlets, which gives the plant a loose slender appearance.

8. *rùbra*, Link, not A. Dietr. (*P. australis*, Small. *P. rubens*, Sarg.). RED SPRUCE. Tree, to 80 ft., or occasionally to 100 ft., with short and slender branches forming a narrow pyramidal head, with red-brown bark: young branches reddish brown: lvs. quadrangular, acute or mucronate, dark or bright green, shining, about $\frac{1}{2}$ in. long: fls. purple: cones oblong, $1\frac{1}{4}$ –2 in. long, green while young, later light reddish brown, glossy;

scales obovate, rounded and entire or slightly erose at the margin. From Canada to N. C., along the Alleghany Mts. S.S. 12:597.—Handsome tree, but requires cool and moist situation and is less drought-enduring than most others. Var. *virgata*, Rehd., is a sparingly branched form with long and slender branches destitute of branchlets, very similar to *P. excelsa* var. *virgata*. G.F. 8:45.

9. *mariana*, BSP. (*P. nigra*, Link. *P. brevifolia*, Peck). The native BLACK SPRUCE. Figs. 2942, 2943. Tree, usually to 20–30 ft. or occasionally to 100 ft., with slender, often pendulous branches forming a narrow,

2943. Cones of piceas. Largest one, *P. pungens*; lowest one, *P. canadensis*; upper right hand, *P. mariana*. ($\times \frac{1}{2}$)

irregular head: bark gray-brown: young branches brown or yellowish brown: lvs. quadrangular, obtusish, dull dark or bluish green, bloomy especially on the upper side, $\frac{1}{4}$ – $\frac{3}{4}$ in. long: fls. purple: cones oval-oblong, globose-ovate when open, dark purple while young, later dull grayish brown, $\frac{1}{2}$ – $1\frac{1}{2}$ in. long; scales rounded and finely denticulate at the margin. From Canada to Va., Minn. and Brit. Col. S.S. 12:596.—Very variable in habit; cone-bearing trees often only a few feet high when growing in swamps. The most ornamental garden form is var. *Doumètii*, Schneid. (*P. nigra Doumètii*, Carr.), with ascending crowded branches forming a dense conical pyramid. A similar form, somewhat broader at the base with more light bluish green foliage, is var. *Beissneriana*, Rehd. (*P. nigra mariana*, Beissn.). G.C. III. 11:80. Var. *fastigiata*, Rehd. (*P. nigra fastigiata*, Carr. *Abies nigra pumila*, Knight). A columnar form with ascending branches and short, acute lvs. Var. *nana*, Rehd. (*P. nigra nana*, Beissn.). A dwarf subglobose form with light bluish green lvs. Gt. 50, p. 193.

10. *canadensis*, BSP. (*P. alba*, Link. *P. larx*, Sarg.). The native WHITE SPRUCE. Figs. 2943, 2944. Tree, usually 60–70 ft., with ascending branches and usually pendent branchlets: bark light brownish gray: lvs. slightly curved, acute or acutish, more or less bluish green, $\frac{1}{2}$ – $\frac{3}{4}$ in. long, of a strong, aromatic odor when bruised: fls. pale red or yellowish: cones cylindric-oblong, light brown and glossy, $1\frac{1}{2}$ –2 in. long; scales orbicular, with usually entire margin, thin and flexible. From Labrador to Alaska, south to Mont., Minn., and N. Y. S.S. 12:598. G.F. 8:223 (adapted in Fig. 2944); 9:355. F.S. 21:2251. C.L.A. 11:311. F.E. 29:81. Gn. M. 4:19. M.D.G. 1899:80.—A decorative species of dense habit when young and with rather light bluish green foliage; it endures heat and drought much better than the two preceding species. The most important garden form is var. *cærùlea*, Schneid. (*P. alba cærùlea*, Carr. *P. alba argentea* and var. *glauca*, Hort. *Abies rubra violacea*, Loud.). Of dense habit with light bluish green or almost silvery white lvs. Var. *péndula*, Schneid. (*P. alba péndula*, Beissn.). With pendulous branches. An important geographical variety is var. *albertiana*, Rehd. (*P. albertiana*, S. Br. *P. alba albertiana*, Beissn.). Tree, to 100 or occasionally 150 ft., of narrow pyramidal habit: branchlets sometimes minutely pubescent: lvs. more crowded: lf.-cushions longer: cones shorter with more rigid rounded scales. Alberta. M.D.G. 1905:117 (as *P. alba*).

Section II. CASICTA, Mayr.

Lvs. quadrangular or more or less compressed: scales of cone loosely appressed before maturity, rhombic and usually elongated, erose-denticulate, and more or less wavy on the margin.

11. *Engelmannii*, Engelm. (*P. columbiana*, Lemmon). *Abies commutata*, Murr.). ENGELMANN SPRUCE. Tree, to 150 ft., with slender spreading branches in closely arranged whorls, forming a dense and narrow pyramid in young trees: winter buds with brownish yellow usually appressed or little spreading scales: young branches pale brownish yellow, pubescent: lvs. slender, straight or slightly incurved, acute, bluish green to steel-blue, $\frac{1}{2}$ -1 in. long, without resin canals, of a strong aromatic odor when bruised: fls. purple: cones oval- to cylindric-oblong, light brown, $1\frac{1}{2}$ -3 in. long; scales rhomboidal, narrowed and truncate or rarely acute at the apex. From Alberta and Brit. Col. to Ariz. and New Mex. S.S. 12:599. Gn.M. 2:26. F.E. 27:39. M.D.G. 1905:121, 122.—A very ornamental tree, varying in the color of foliage. Var. *glauca*, Beissn., has bluish or steel-blue, and var. *argentea*, Beissn., silvery gray foliage. M.D.G. 1906:557. *P. pseudopungens*, Dieck, seems not to differ from typical *P. Engelmannii*. The latter is said to be sold for *P. pungens*. It is more common, and its seeds are therefore more readily secured.

12. *pungens*, Engelm. (*P. Parryana*, Sarg. *Abies Menziesii*, Engelm., not Lindl.). COLORADO SPRUCE. Fig. 2943. Tree, 80-100, or occasionally to 150 ft., with horizontal stout branches in rather remote whorls, forming a broad, regular pyramid: winter buds with brownish yellow usually reflexed scales: young branches glabrous, bright yellowish brown: lvs. rigid, incurved, spiny-acuminate, bluish green to silvery white or rarely dull green, $\frac{3}{4}$ -1 $\frac{1}{2}$ in. long, with 2 resin canals: cones cylindric-oblong, light brown and glossy, $2\frac{1}{2}$ -4 in. long; scales rhomboidal, narrowed and erose at the apex. Wyo. to Colo. and Utah. S.S. 12:600. G.C. II. 20:725; III. 10:547. Mn. 7, p. 51. Gng. 7:49. S.H. 2:273. F. 1884, p. 5. G.M. 40:35.—A very handsome and very hardy tree of symmetrical habit, with light, sometimes almost silvery white foliage. According to the different shades of color of the foliage, the following varieties are distinguished: Var. *glauca*, Beissn. With bluish green lvs. Gn. 63, p. 280. G.M. 50:121. Gn. M. 2:26. G.W. 1, p. 355; 14, p. 14. R.B. 32, p. 106. Var. *caerulea*, Beissn. With bluish white foliage. G.W. 1, p. 357. Var. *argentea*, Beissn. With silvery white foliage. Gt. 53, p. 493. G.W. 2, p. 295; 8, p. 481; 10, p. 48. M.D.G. 1901:178. Var. *Kosteri*, Beissn. With silvery white foliage and of very regular pyramidal habit. G.W. 15, p. 467. F.E. 16:461; 18:82. Var. *glauca pendula*, Beissn. With bluish foliage and pendulous branches. R.H. 1901, p. 183. F.E. 32:1173. G.W. 6, p. 399; 9, p. 543; 16, p. 79. M.D.G. 1901:133. Var. *viridis*, Regel (*P. commutata*, Hort.), is the form with green lvs. Var. *compacta*, Rehd. A dwarf compact form; originated at the Arnold Arboretum. Var. *aurea*, Niemetz. With golden yellow foliage. Var. *flavescens*, Niemetz. With whitish yellow foliage. Var. *Morheimii*, Rujis. Grows more compact and foliage deeper blue.

13. *sitchensis*, Carr. (*Abies Menziesii*, Lindl.). TIDELAND SPRUCE. SITKA SPRUCE. Tree, usually 100 ft., occasionally 200 ft. high, with slender horizontal branches, forming a broad pyramid in young trees; in old trees the upper branches short and ascending, the lower ones slender and spreading, clothed with slender

branchlets: bark bright or dark red-brown: young branches rigid, light brownish yellow, glabrous: lvs. bright green, shining and rounded on the lower side, flat, slightly ridged and silvery white on the upper side, sharply acute or acuminate, $\frac{1}{2}$ -1 in. long: staminate fls. red: cones cylindric-oval, pale yellowish or reddish brown, $2\frac{1}{2}$ -4 in. long; scales rounded at the apex and erose. Alaska to Calif. G.C. II. 25:728, 729. S.S. 12:602. G.F. 4:211 (erroneously named Douglas fir). M.D.G. 1896:403; 1905:123.—A very ornamental tree, especially attractive by the contrasting colors of the foliage, but it can hardly be grown successfully in the eastern states; it does not stand the hot summers well, and is probably not hardy farther north than Mass. Var. *speciosa*, Beissn., is of slower growth and more compact habit, with more ascending branches and shorter, more rigid lvs.

14. *jezoensis*, Maxim. (*P. ajanensis*, Fisch. *Abies jezoensis*, Sieb. & Zucc. *Abies Alcockiana*, Veitch, partly). Tree, 100-150 ft., or occasionally higher, with horizontally spreading slender branches: bark dark gray: young branches glabrous, shining, yellowish brown or yellowish green: lf.-cushions slightly swollen, with usually recurved petioles: lvs. slightly curved, acute, slender, slightly ridged on both sides, dark green and shining below, silvery white above, $\frac{1}{2}$ - $\frac{3}{4}$ in. long: fls. carmine: cones oblong, light brown, $1\frac{1}{2}$ -3 $\frac{1}{2}$ in. long; scales oval-oblong, erose. E. Siberia, Amurland, Saghalin, N. Japan. G.C. II. 13:115, 212; III. 3, p. 53. J.H.S. 26, p. 104. S.I.F. 2:3. Gt. 38, p. 217, figs. 2-5. Var. *hondoensis*, Rehd. (*P. hondoensis*, Mayr. *P. ajanensis* var. *microsperma*, Beissn., not Mast.). Tree, to 100 ft.: branchlets light reddish brown with much swollen lf.-cushions: lvs. shorter, more obtuse, dull green below. Cent. Japan. B.M. 6743. J.H.S. 26, p. 103. R.H. 1903, p. 341, and G.W. 1:358 (as *P. ajanensis*). S.I.F. 1:5.—The type is rarely cult; it does not grow well in the eastern states and suffers sometimes from late frosts, owing to its early leafing. The variety is much more satisfactory; it is not likely to suffer from frost, as it leafs later, and is a highly ornamental perfectly hardy tree.

15. *purpurea*, Mast. Tree, to 60 ft. with wide-spreading branches: branchlets orange-yellow, hispid: winter buds broadly ovoid: lvs. quadrangular, more or less compressed, curved, obtuse or acutish, with 2 white bands above, green beneath, sometimes with a few stomata, $\frac{1}{2}$ - $\frac{1}{2}$ in. long: cones cylindric-oblong, 2-2 $\frac{1}{2}$ in. long, purple, even more or less so at maturity; scales rhombic-oblong, contracted, narrowed from about the middle, erose-denticulate, acutish or truncate at the apex. W. China.—Very handsome with its numerous purple cones.

Section III. OMORIKA, Mayr.

Lvs. more or less compressed, with glaucous lines above, green below: scales of cone closely appressed before maturity, broad and entire or nearly so on the margin.

16. *bicolor*, Mayr (*P. Alcockiana*, Carr., partly. *Alcockiana nova*, Hort. *Abies bicolor*, Maxim.). Tree, 80-150 ft., with rather stiff, spreading branches: bark grayish brown: young branches dull yellowish brown, glabrous, usually only leading shoots pubescent: lvs. somewhat curved, with 2 bluish lines above, dark green beneath, sharply acuminate, $\frac{1}{2}$ - $\frac{3}{4}$ in. long: cones oblong, brown, purple before ripening, 3-4 in. long; scales obovate, finely denticulate and slightly wavy at the often recurved margin. Japan. G.C. II. 13, p. 213. C.L.A. 11:311. Gn.M. 2:24. R.H. 1903, p. 340. S.I.F. 1:4.—Handsome tree, with less slender branches than *P. jezoensis* and of more rapid growth. Var. *acicularis*, Shirasawa (*P. acicularis*, Maxim. *P. japonica*, Regel). Branchlets finely pubescent: lvs. curved, acute, bluish white above: cones light reddish

2944. *Picea canadensis*. Abnormal spikes pistillate at apex.

brown, with entire not wavy scales. Cent. Japan. M.D. 1914:257. Var. *reflexa*, Shirasawa. Branchlets pubescent, light brown: lvs. more or less curved, acute, bluish white above, about $\frac{1}{2}$ in. long: cones light reddish brown; scales nearly entire, not wavy, at the apex slightly attenuate and recurved. Cent. Japan. M.D. 1914:257.

17. *Omōrika*, Bolle (*Pinus Omōrika*, Panic). Tree, to 100 ft. or higher, with rather short spreading and ascending branches forming a narrow pyramidal head: young branches brown, pubescent: lvs. compressed, ridged on both sides, obtuse and mucronulate, dark green and shining below, with whitish lines above, $\frac{1}{3}$ – $\frac{1}{2}$ in. long: fls. purple: cones ovate-oblong, cinnamon-brown, glossy, $1\frac{1}{2}$ – $2\frac{1}{2}$ in. long; scales almost orbicular, with finely denticulate margin. S. E. Eu. G.C. II. 21:308; III. 21:153. Gt. 47, p. 177. R.H. 1905, p. 239.—Handsome tree of rather slow growth, forming a dense and narrow pyramid when young; very hardy.

18. *Breweriāna*, Wats. Tree, 80–120 ft. high, with the branches at the top slightly ascending, the lower ones horizontal or pendulous, with whip-like pendulous branchlets often 7 or 8 ft. long, furnished with similar, slender lateral branchlets; young branches reddish brown, pubescent: lvs. straight or slightly curved, obtuse, rounded and dark green at the lower surface, almost flat and with white lines above, $\frac{3}{4}$ –1 in. long: staminate fls. purple: cones oblong, $2\frac{1}{2}$ –5 in. long, light orange-brown; scales obovate, with entire margin. Siskiyou Mts. in Ore. and N. Calif. S.S. 12:601. G.F. 3:66, 67; 5:595. G.C. II. 25:497. M.D.G. 1905:123.—One of the most distinct spruces, but does not seem to do well in the eastern states.

The Roman figure indicates the section to which the species belongs: *P. ascendens*, Patschke. (Section III.) Tree, to 80 ft.: branchlets pale brown, glabrous: lvs. about $\frac{3}{4}$ in. long, compressed, with 2 white lines above: cones 3–4 in. long, with obovate truncate scales. W. China.—*P. aurantiaca*, Mast. (I.) Allied to *P. asperata*. Tree, to 40 ft., with pale gray bark: branchlets orange, glabrous: lvs. quadrangular, about $\frac{1}{2}$ in. long: cones 4–5 in. long, brown, with broad, rounded, slightly erose scales. W. China.—*P. Balfouriana*, Rehd. & Wilson. (II.) Allied to *P. purpurea*. Tree, to 120 ft.: branchlets villous, yellowish: lvs. $\frac{1}{2}$ – $\frac{3}{4}$ in. long, compressed, whitish above, acute or obtusish: cones purplish, $2\frac{3}{4}$ – $3\frac{1}{2}$ in. long, with rhombic denticulate scales. W. China.—*P. brachytyla*, Pritz. (*P. pachyclada*, Patschke). (III.) Tree, to 70 ft.: branchlets brown, nearly glabrous: lvs. $\frac{1}{2}$ in. long, compressed, white above: cones 3–4 in. long, with obovate scales entire at the margin. W. China.—*P. complanata*, Mast. (III.) Tree, to 80 ft., with gray bark: branchlets orange-brown, pubescent or sometimes glabrous: lvs. flattened, acute, white above, $\frac{3}{4}$ in. long: cones reddish brown, 5–6 in. long, with broad rounded or truncate scales. W. China. G.C. III. 39:147.—*P. Glehnii*, Mast. (III.) Tree, to 150 ft.: branchlets brown, pubescent: lvs. $\frac{1}{2}$ in. long, obtusely quadrangular, whitish above, green beneath: cones brown, violet-purple while young, $1\frac{1}{2}$ –2 in. long, with broad rounded erose scales. Amurl., Saghalin, N. Japan. G.C. II. 13:301. S.I.F. 2:3.—*P. heterolepis*, Rehd. & Wilson. (I.) Allied to *P. asperata*. Tree, to 80 ft.: branchlets brownish, glabrous: lvs. quadrangular, thick, pungent, $\frac{1}{2}$ – $\frac{3}{4}$ in. long: cones $3\frac{1}{2}$ – $5\frac{1}{2}$ in. long, pale brown, with rigid rhombic-obovate scales, emarginate or bifid at the apex. W. China.—*P. Koyamai*, Shirasawa. (III.) Allied to *P. Glehnii*. Tree, to 30 ft.: branchlets bright reddish brown, glabrous: lvs. quadrangular, $\frac{1}{2}$ – $\frac{1}{2}$ in. long, acute, bluish white above: cones light brownish green, $1\frac{1}{2}$ – $2\frac{1}{2}$ in. long; scales broadly obovate, rounded, entire. Cent. Japan. M.D. 1914:257.—*P. Ukiangensis*, Pritz. (II.) Tree, to 80 ft.: branchlets light yellow-gray, sparingly hairy: lvs. quadrangular, slightly compressed, $\frac{1}{2}$ in. long, white above: cone about 2 in. long with rhombic-ovate, erose, flexible scales. W. China.—*P. Mastersii*, Mayr.—*P. Wilsonii*,—*P. Maximowiczii*, Regel (*P. Tschonoskii*, Mayr. *P. excelsa* var. *obovata japonica*, Beissn.). (I.) Allied to *P. obovata*. Small bushy tree: branchlets reddish brown, glabrous: lvs. rigid, pointed, spreading, about $\frac{1}{2}$ in. long: cones $1\frac{1}{4}$ –2 in. long, lustrous brown, with broad rounded scales. Japan.—*P. Meyerii*, Rehd. & Wilson. (I.) Allied to *P. asperata*. Medium-sized tree: branchlets cinnamon-brown, hairy: lvs. quadrangular, slightly compressed, curved, obtusish, $\frac{1}{2}$ – $\frac{3}{4}$ in. long: cones $2\frac{1}{2}$ – $3\frac{1}{2}$ in. long, lustrous brown, with rounded or truncate scales. N. China.—*P. montigena*, Mast. (II.) Tree, to 100 ft.: branchlets pale brown, hairy: lvs. quadrangular, $\frac{1}{2}$ in. long, curved, acute: cones brown, 3–4 in. long, with rhombic-ovate, flexible, erose scales. W. China. G.C. III. 39:146 (except the cone).—*P. morindosa*, Rehd.—*P. spinulosa*,—*P. Moseri*, Mast. (*P. jezoensis* x *P. mariana* Doumetii). Branchlets smooth, olive: lvs. quadrangular, acute, $\frac{1}{2}$ – $\frac{3}{4}$ in. long, glaucous above, green below. Garden origin. J.H.S. 26:105.—*P. pachyclada*, Patschke—*P. brachytyla*,—*P. retroflexa*, Mast. (I.) Tree, to 120 ft.: branchlets glabrous, rarely slightly hairy, bright yellow, rarely brownish orange: lvs. quad-

angular, pungent, $\frac{1}{2}$ –1 in. long: cone lustrous brown, 3–4½ in. long, with obovate, rounded, stiff scales. W. China.—*P. Sargentiana*, Rehd. & Wilson. (III.) Tree, to 70 ft.: branchlets yellow or orange, glandular: lvs. compressed, acuteish or obtuse, about $\frac{1}{2}$ in. long, white above, lustrous green beneath: cones $2\frac{1}{2}$ –5 in. long, brown, with obovate, rounded or truncate scales. W. China.—*P. spinulosa*, Griff. (*P. morindoides*, Rehd.). (III.) Tree, with spreading branches and slender pendulous branchlets: lvs. 1–1½ in. long, pungent, slightly compressed, glaucous above: cone 3–4 in. long, yellowish brown, with rhombic obovate scales minutely denticulate. E. Himalayas. B.M. 8169. G.C. III. 39:218, 274. R.H. 1908, p. 517. G.M. 51:47. S.T.S. 1:48. Tender.—*P. Tschonoskii*, Mayr.—*P. Maximowiczii*,—*P. Watsoniana*, Mast. (I.) Tree, to 40 ft.: branchlets glabrous: lvs. quadrangular, slender, $\frac{1}{2}$ in. long, bright green: cones $2\frac{1}{2}$ – $3\frac{1}{2}$ in. long with obovate, rounded scales. W. China.—*P. Wilsonii*, Mast. (*P. Mastersii*, Mayr.). (I.) Tree, to 80 ft.: branchlets glabrous, pale gray: winter buds ovoid, dark brown, lustrous: lvs. quadrangular, curved, acute, $\frac{1}{2}$ in. long: cones cylindric-oblong, $1\frac{1}{2}$ –2 in., brown; scales suborbicular, entire, finally recurved at margin. Cent. China. G.C. III. 33:133. Not in cult. are the following species: *P. gemmata*, Rehd. & Wilson, *P. hirtella*, Rehd. & Wilson, *P. Neoveitchii*, Mast. (G.C. III. 33:116), from China, and *P. Morrisonicola*, Hayata, from Formosa.

ALFRED REHDER.

PICKEREL-WEED: *Pontederia*.

PICOTEE: *Carnation*.

PICRÁSMIA (Greek, *pikrasmos*, bitterness; referring to the bitter bark and wood). Including *Picræna*, *Simarubaceæ*. Trees and shrubs, with alternate odd-pinnate lvs., yellowish green fls. in axillary long-peduncled loose cymes, and subglobose dry berry-like fr. About 8 species in S. and E. Asia and W. India. *P. quassioides*, Bennett (*P. aitanthoides*, Planch. *P. japonica*, Gray), seems to be the only species in cult. It is an upright shrub or small tree to 30 ft., almost glabrous except the tomentulose infl.: lvs. with 4–8 pairs of lfts.; lfts. ovate or oblong-ovate, acuminate, crenately serrate, $2\frac{1}{2}$ – $3\frac{1}{2}$ in. long: fr. pea-sized, bright red, with 1 seed. Himalayas, China, Japan. S.I.F. 1:53. This is probably the hardest species of the genus, and has proved hardy at the Arnold Arboretum in favorable positions but needs protection while young. Its chief ornamental value consists in the handsome foliage turning orange and scarlet in fall and in the bright red frs. Wood and bark are exceedingly bitter. The wood of some species, especially *P. excelsa*, Planch., from W. Indies, is used in medicine like that of *Quassia*.

ALFRED REHDER.

PIE-PLANT: *Rhubarb*.

PIÉRIS (a mythological name). Including *Portuna*, *Ericaceæ*. Ornamental shrubs, grown chiefly for their handsome white flowers.

Evergreen or deciduous shrubs or rarely small trees: lvs. alternate, short-petioled, entire or serrulate: fls. in often paniced racemes or in axillary clusters forming terminal racemes; calyx-lobes valvate or distinct; corolla globose or urceolate, with 5 short lobes; stamens 10; anthers obtuse, with a pair of awns near the base or the filaments 2-toothed below the apex: caps. with 5 dehiscent valves; seeds linear-oblong, not winged, with membranaceous testa.—About 10 species in N. Amer. and in E. Asia south to the Himalayas. Often included under *Andromeda*. Closely allied to *Lyonia*, which is distinguished by its awnless anthers, and to *Zenobia*, which has the anthers 4-awned at the apex. The foliage of some species is said to be poisonous to cattle.

The pieris are handsome shrubs with medium-sized oval to lanceolate leaves and with rather small white flowers in large terminal panicles or in racemes. The evergreen *P. floribunda* and the deciduous *P. mariana* are hardy North and, like the other species, are valuable for the earliness of their flowers. The most beautiful are *P. japonica* and *P. formosa*; the first thrives still in Massachusetts in sheltered positions, but the flowers are usually winter-killed, while *P. formosa* can be grown only South. They are easily forced, and *P. japonica* especially may be recommended for this purpose; it makes a very handsome and graceful pot-plant for

inside decoration with its slender racemes of pure white flowers hanging over the glossy bright green foliage. The species of *Pieris*, like other *Ericaceae*, grow well in a moderately moist well-drained and porous soil, but dislike limestone and heavy clay; a partly shaded situation suits them best. Propagation is by seeds treated like those of azalea or rhododendron; also by layers, and the evergreen kinds by cuttings of almost ripened wood in August under glass, kept during the winter in a cool greenhouse. They root very slowly; cuttings taken from forced plants root more readily.

- A. Lvs. evergreen.
B. Fls. in terminal panicles formed the previous year and remaining naked during the winter: lvs. serrulate.

- C. Panicles upright. floribunda, Benth.

& Hook. (*Andrōmeda floribunda*, Pursh. *Portūna floribunda*, Nutt.). Fig. 2945. Dense shrub, 2-6 ft. high: branches and petioles with strigose brown hairs: lvs. ovate to oblong-lanceolate, acute, minutely serrulate and setosely ciliate, otherwise glabrous, $1\frac{1}{2}$ - $2\frac{1}{2}$ in. long: fls. nodding, in terminal dense upright panicles $1\frac{1}{2}$ -4 in. long; corolla ovate, strongly 5-angled, white, $\frac{1}{4}$ in. long. April, May. Va. to Ga., in the Alleghany Mts. B.M. 1566. B.R. 807. G.C. III. 45:408. Gn. 31, p. 612. Gn.M. 6:280. Mn. 5, p. 132. M.D.G. 1898:333.—Very desirable evergreen shrub for its hardness and earliness of the fls.

cc. Panicles drooping.

japonica, D. Don (*Andrōmeda japonica*, Thunb.). Fig. 2946. Shrub, with spreading branches or sometimes small tree to 30 ft.: branches glabrous: lvs. crowded at the ends of branches, obovate-lanceolate or oblanceolate, crenately serrulate, narrowly cuneate at the base, glabrous, $1\frac{1}{2}$ - $2\frac{1}{2}$ in. long: fls. in pendulous panicles, $2\frac{1}{2}$ -5 in. long; corolla ovate, not angled, $\frac{1}{4}$ in. long. April, May. Japan. R.B. 11:10. B.H. 21:19. Gn. 12:98, and p. 424; 50, p. 307; 57, p. 399. G.C. II. 17:797. M.D.G. 1898:544. G.W. 9, p. 354. J.H. III. 51:109. G.M. 55:199. G. 24:141; 27:182; 31:593. S.I.F. 1:78. Var. *albo-marginata*, Rehd. Lvs. with whitish margin and smaller. Var. *pygmaea*, Maxim. Dwarf form with small linear-oblanceolate lvs. Japanese botanists speak of a variety with the racemes a foot and more long; this form seems to be not yet intro. *P. japonica* is one of the most graceful early-blooming evergreens.

formosa, D. Don (*Andrōmeda formosa*, Walt.). Shrub or small tree, to 20 ft.: branchlets glabrous: lvs. crowded at the end of the branchlets, elliptic-oblong to lanceolate, acuminate, broadly cuneate at the base, finely serrulate, glabrous, lustrous above, 2-5 in. long: fls. in terminal drooping or spreading panicles, to 6 in. long; corolla urceolate, white or tinged with pink, $\frac{1}{2}$ in. long. April, May. E. Himalayas. B.M. 8283. G.C. II. 15:569. Gn. 54, p. 77. G. 27:183; 35:425, 427. I.H.

2945. *Pieris floribunda*. (×½)

5:162.—Very similar to the preceding species, but larger in every part; less hardy.

- BB. Fls. in axillary clusters, forming terminal leafy racemes: lvs. entire.

lucida, Rehd. (*P. nitida*, Benth. & Hook. *Andrōmeda lucida*, Jacq. *A. nitida*, Bartr. *A. coriacea*, Ait. *Lyonia nitida*, Fern. *L. lucida*, Koch). FETTER-BUSH. Shrub, 2-6 ft. high, with triangular branches, quite glabrous: lvs. obovate or broadly elliptic to oblong, narrowed at both ends, bright green and shining above, entire and slightly revolute at the margin, $1\frac{1}{2}$ -3 in. long: corolla cylindric-ovate, white to pink, $\frac{1}{4}$ - $\frac{1}{2}$ in. long: caps. ovoid-globose, with ridges at the sutures. March-May. N. C. to Fla. and La. B.M. 1095. Var. *rubra*, Rehd. (*Andrōmeda coriacea rubra*, Lodd.). Fls. deep pink. L.B.C. 7:672.

- AA. Lvs. deciduous or half-evergreen, entire: fls. in racemes.

mariana, Benth. & Hook. (*Andrōmeda mariana*, Linn. *Lyonia mariana*, D. Don. *Leucothoe mariana*, DC.). STAGGER-BUSH. Fig. 2947. Deciduous shrub, 2-4 ft. high, glabrous or nearly so: lvs. oval to oblong, obtuse or acute, usually cuneate at the base, entire, 1-3 in. long: fls. nodding, in axillary clusters on leafless branches of the previous year, forming 2-5 in.-long racemes; corolla cylindric-campanulate, white or pale pink, almost $\frac{1}{2}$ in. long: caps. ovate-pyramidal. April-June. R. I. to Fla. B.M. 1579. Mn. 2:47. G.O.H. 113. A.G. 10:281 (adapted in Fig. 2947).—The foliage is said to poison lambs and calves.

ovalifolia, D. Don (*Andrōmeda ovalifolia*, Wall.). Half-evergreen or deciduous shrub or tree, to 40 ft.: branchlets glabrous: lvs. coriaceous, ovate or elliptic to ovate-oblong, short-acuminate or acute, usually rounded at the base, glabrous or hairy on the veins beneath, 2-6 in. long: fls. in simple lateral racemes with a few lvs. at the base, 2-6 in. long; sepals ovate to triangular-lanceolate; corolla oblong-urceolate, white, slightly pubescent outside, $\frac{1}{2}$ in. long. May-June. Himalayas. Var. *lanceolata*, Clarke (*P. lanceolata*, D. Don). Lvs. elliptic-oblong to elliptic-lanceolate, narrowed at the base, smaller: sepals greenish, oblong to lanceolate. Himalayas, China. Var. *elliptica*, Rehd. & Wilson (*P. elliptica*, Sieb. & Zucc.). Lvs. thinner,

2946. *Pieris japonica*. (×½)

deciduous, elliptic-ovate to ovate-oblong. Japan, China. S.I.F. 2:60. This variety is hardier than the type.

P. phyllireafolia, DC. Evergreen shrub, 1-2 ft., glabrous: lvs. oblong, serrulate near the apex, 1-2 in. long: racemes axillary, 4-12-fl.; corolla ovoid, white. Feb., March. W. Fla. B.R. 30:36. H.I. 2:122.

ALFRED REHDER.

PIGAFETTA (derivation not known). *Palmaceae*. Tall palms: sts. stout, aculeate above, remotely annulate below, creeping at base: lvs. terminal, pinnate;

divided; segms. opposite and alternate, lanceolate, acuminate; spadix paniculate, much branched, pendulous; fls. polygamous-monoecious; male calyx obconic, truncate or obscurely 3-toothed; petals 3, free, lanceolate, valvate; stamens 6, filaments short, thick; ovary an inconspicuous rudiment: fr. globose or oblong, 1-celled. About 5 species, Malaya. *P. elata*, Wendl. (*Hyospathe elata*, Hort. *Metroxylon elatum*, Mart.). Trunk of very hard wood, erect, naked: lvs. spreading

2947.
Pieris mariana.

and drooping, similar to those of *Cocos*; petioles thick and having long bristles which become spiny with age: infl. long, spadices with pendulous branches: fr. with a solitary blackish seed. Celebes. Cult. occasionally abroad; for treatment, consult article *Palm*.

PILEA (*pileus*, a Roman cap: one of the segments of the perianth in the first described species covering the achene). Syn., *Adicea*. *Urticaceæ*. Mostly weedy plants, but forms of one or two species are grown in greenhouses for their compact fern-like sprays and for the interesting phenomenon of forcibly discharging the pollen, whence the name "artillery plant."

Annual or perennial herbs, glabrous or pubescent: lvs. opposite, usually strongly 3-nerved; fls. monoecious or dioecious, mostly very small and in axillary clusters; stamens 3-4, and the sepal-lobes in the staminate fls. of the same number; sepal-lobes of pistillate fls. 3, the ovary 3-angled and erect and bearing a sessile tufted stigma, with 3 scale-like staminodia: fr. an achene, ovate or nearly orbicular, compressed, more or less invested in the perianth.—There are 150 or more species of *Pilea* in the tropics, chiefly of Amer., and few extra-tropical; one, *P. pumila*, is a small nettle-like but stinging plant growing in the northern states.

The artillery plants of the gardens are small branchy half-succulent herbs, usually grown in pots and allowed to reach a foot or so in height. The gracefully curving fronds of small ovate or obovate shining leaves are much prized. They are easy to grow, being propagated by cuttings. They thrive best when given an abundance of water. Sometimes they are used as edgings in

orchid houses, to screen the pots with green, and they also tend to equalize the moisture conditions and thereby contribute to the welfare of the orchids. When the staminate flowers open, the pollen is usually discharged forcibly and visibly. If a plant is put in a sunny place when the pollen is ripe, it may set up a vigorous bombardment, particularly if the foliage is sprayed. (See I.H. 1, p. 64, 1854, for an account of this phenomenon.) The artillery plant is seen in nearly every greenhouse, but whether there is more than one species in common cultivation it is not easy to determine, for specific characters are difficult to draw. The leaves, although opposite, are unequal. Usually the branchlets develop alternately on the branch. The species are confused.

muscosa, Lindl. (*P. microphylla*, Liebm.? *P. callitrichoides* of some authors). Monoecious: small, rather weak plant: lvs. less than $\frac{1}{4}$ in. long as a rule, sometimes very small: fl.-clusters mostly sessile or nearly so. Mex., W. Indies, S. Amer.—Whether the plant in cult. is really the *P. muscosa* originally described by Lindley is in question. The plants are variable and characters apparently not well understood. *P. microphylla*, Liebm., is reported in Fla.

serpyllifolia, Wedd. (*P. muscosa*, Hort., in part. *P. callitrichoides* of some). Fig. 2948. Dioecious: plant usually stronger and more upright: lvs. usually $\frac{1}{4}$ in. or more long, and fl.-clusters more peduncled. Mex.—Seems to be the commoner species, but it is difficult to determine them.

L. H. B.

PILOCÁRPUS (Greek, *pilos*, a cap, and *karpos*, a fruit, from the shape of the fruit). *Ruticææ*. Shrubs or small trees, sometimes attaining 10 feet.

Leaves pinnately compound, of 1-4 pairs and a terminal lft.; lfts. opposite, but the lvs. usually alternate: fls. in elongated racemes; petals 4-5, valvate; stamens 4-5; ovary 4-5-lobed, not tubercled.—Seventeen species, natives of Trop. Amer., principally Brazil. The plants of the genus form the source of the alkaloid "pilocarpine," and together with plants of several other genera, the source of the drug "jaborandi."

pennatifolius, Lem. Branchlets glabrous or puberulent: lvs. alternate, 1-1½ ft. long; lfts. 2 or 3 pairs, besides the terminal one, 3-9 in. long, oblong; apex rounded or emarginate, coriaceous, yellowish green:

2948. Artillery plant.—*Pilea serpyllifolia*.
(Left-hand spray about natural size)

raceme spike-like, many-flid. (about 100): rachis stout, pedicels stout, horizontal, with 2 small greenish tooth-shaped bracts at their bases: fls. reddish brown, rotate. Brazil. B.M. 7235. J.F. 3:263.—Intro. into Calif. and said to be hardy in the open wherever the lemon can be successfully grown.

racemösus, Vahl. A small tree or shrub, 6-15 ft. high: lfts. 1-5, lance-elliptic to oval or obovate, refuse at the apex, cuneate or somewhat rounded at the base,

entire, coriaceous, pellucid-punctate; petals ovate or oblong-ovate, acute; filaments subulate; fr. a dark brown or blackish follicle; seeds glabrous. W. Indies. —Intro. into Calif.

P. Jaborandi, Holmes, has been described as *P. pennatifolius*, by Benth. & Trim., but is distinguished from it by shorter lvs. and lfts., stiffly pubescent branchlets and sts., more openly fld. racemes, with slender rachis and pedicels, and the presence of 2 inconspicuous bracteoles above the middle of the fl.-pedicels. B.M. 7483.

ARNOLD V. STUBENRAUCH.
F. TRACY HUBBARD.†

PILOCÈREUS of the "Cyclopedia of American Horticulture" is mostly *Cephalocereus*. *P. Celsianus* = *Cero-cereus*. *P. chrysomallus* and *P. Columna-Trājani* = *Pachycereus*. *P. Dautwitzii* = *Oreocereus*. *P. Houlettii*, Auth. = *Cephalocereus Sartorianus*. *P. Schottii* = *Lophocereus*. *P. Strausii* = *Oreocereus Celsianus*.

PILOGYNE: *Melothria*.

PIULÀRIA (Latin, *a little ball*, alluding to the shape of the involucre). *Marsileaceæ*, one of the fern allies. Small aquatic plants, sometimes used in ponds: rootstock filiform, creeping, rooting at the nodes: barren fronds reduced to filiform stipes, few or clustered at the nodes: involucre solitary at the nodes, sessile or shortly stipitate, globular: sori 2-4, vertically adnate. —About 6 species, Eu., W. Asia, Austral., New Zeal., and N. Amer.

globulifera, Linn. Rootstock creeping under water, often to a considerable extent; barren fronds filiform, bright green, like the lvs. of *Isoetes*, 1-3 in. long, usually few together at the nodes: involucre about the size of a pea, slightly hairy, sessile or borne on very short erect or recurved stipes. Eu., W. Asia, and Austral.

PILUMNA: *Trichopilia*.

PIMÈLEA (Greek, *fat*, referring to the fleshy seeds). *Thymelæaceæ*. RICE-FLOWER. Mostly shrubs, fitted for greenhouse culture, although reported to be hardy in the open wherever the lemon can be grown successfully.

Woody, or rarely herbaceous, with small opposite or alternate, always simple and entire lvs.: infl. usually a terminal head or cluster, never umbellate, often with an involucre of 4 or more bracts at the base: fls. hermaphrodite or functionally dioecious, white, pink or reddish, small but showy in the clusters and the bracts are often colored; perianth tubular, with a spreading (rarely erect) 4-lobed limb, the throat sometimes folded or thickened but without scales; stamens 2, inserted in the throat opposite the 2 outer perianth-lobes; ovary 1-celled: fr. a small drupe, included in the base of the perianth. —Austral. and New Zeal. Of the 80 or more species, only 3 or 4 (as *P. ferruginea*, *P. ligustrina* and *P. spectabilis*) are much known in cult. here, but there are other very showy species, some of which are grown in the Old World.

These fine evergreen shrubs may be increased readily from cuttings of the young half-ripened shoots in March. Make these cuttings 2 to 3 inches long and place in pans, leaving about an inch between the cuttings. The pans should be filled with a mixture of loam, peat and silver sand in equal parts. See that the pans are well drained. Place where they may have a temperature of 55° to 60° and keep covered with glass. See that they are shaded and moist, and they will soon root. When they have made a fair amount of roots, they may be potted up into small pots, using a mixture of fibrous loam, fibrous peat, and leaf-mold in equal parts, with enough of sand to keep the compost open. Be sure that each pot has plenty of drainage as this is necessary for their welfare. They should be grown in a house where they will get a fair amount of ventilation in the summer and be shaded. The atmosphere should be kept moist by damping down, and the plants should have a good syringing every bright day. In the summer they should

have the tops pinched. The pots may be placed on ashes, and this will help to keep them moist. They are slow-growing plants, and therefore will need but one shift during the summer. When they have filled the pots with roots, they may be shifted into 3- or 4-inch pots, using the same mixture. When the autumn comes, they should be given more ventilation, to ripen up whatever wood they have made. In autumn they may have a temperature of about 50° at night with about 10° rise with sun heat. They will do well in about 45° for a winter temperature, with about 55° to 58° on bright days. In winter, give great care to watering so they will not become too wet, just keeping in a nice moist state. By February they may have any necessary potting, using a mixture of fibrous loam four parts, fibrous peat one part, leaf-mold and well-decayed cow-manure one part each, and enough clean sharp sand to make it porous. Pot firmly. They may now be given a temperature of 50° during the night with about 65° on bright days and by April they should be standing 5° to 8° more. They will now need a shift into 5- or 6-inch pots, and give them a pinch back when they have made a little growth. In summer they may have the strongest growths tied out in a horizontal position. Give the same culture as advised for the previous summer and by the next spring the plants should flower. For established plants, they will require heading in after they are through flowering and encouraged to make growth freely during the summer. Give these plants plenty of syringing as they are liable to be affected with red-spider; their treatment year after year will be similar to that mentioned before, only with larger shifts and to be assisted by weekly applications of liquid manure to give them renewed vigor. (J. J. M. Farrell.)

A. Involucral lvs. absent.

1. *longiflora*, R. Br. Sts. 4 ft. or more high, slender, erect, very leafy: lvs. sometimes alternate, linear, hairy: fls. pure white, hairy externally, long and slender; heads globose, many-fld.; perianth silky; anthers yellow, not exerted. W. Austral. B.M. 3281.

AA. Involucral lvs. reduced to 2 small bracts.

2. *drupacea*, Labill. A straggling shrub 6-8 ft. high or lower: branches leafy: lvs. ovate to oblong-elliptical or oblong-linear, glabrous above, slightly silky hairy beneath, distinctly penniveined: fls. white or tinged with pink, silky hairy; anthers yellow, hardly exerted: heads sessile, few-fld.: fr. a red or black drupe. Victoria, Tasmania. L.B.C. 6:540.

AAA. Involucral lvs. 8, or usually more than 8.

3. *imbricata*, R. Br. Small erect shrub, much branched, from less than ½-1½ ft. high, usually clothed with long, silky hairs, but sometimes glabrous: lvs. usually crowded, alternate or opposite, oblong-lanceolate to linear; involucral lvs. similar to stem-lvs., much shorter than fls.: fls. white, outside hairy; tube cylindrical, heads terminal, globular, many-fld. W. Austral. B.M. 3833 (as *P. nana*, and which is included under var. *piligera* in Fl. Austral.).

AAAA. Involucral lvs. 4-8.

B. Lvs. distinctly penniveined.

c. Fls. white.

4. *hypericina*, A. Cunn. St. erect, slender, to 8 or 10 ft. high: branches not very leafy: lvs. opposite,

elliptic-oblong, smooth; fls. white, hermaphrodite and female on distinct plants, very hairy externally; hermaphrodite fls. longer and more slender: heads many-fld. and crowded.—Very similar to *P. ligustrina*, in fact placed as a variety of it in *Flora Australiensis*; distinguished in having more involucrel lvs. much shorter than the fls. and silky pubescent or hoary. Austral. B.M. 3330.

5. *ligustrina*, Labill. Erect, 5–6 ft. high: lvs. opposite, ovate to oblong or elliptical; involucrel lvs. 4, very rarely 5 or 6, as long as the fl.-tubes, glabrous: fls. sometimes female only, silky hairy, white, in rather large globular heads. Austral., Tasmania. B.R. 1827.

cc. Fls. rose-colored or yellowish.

6. *suavæolens*, Meissn. Erect, often less than 1 ft. high, sometimes branching at base only, reaching 2–3 ft.: branches very leafy: lvs. opposite, ovate-lanceolate to oblong-linear; involucrel lvs. 4–8, usually as long as the fls. and ciliate: fls. yellowish when fresh, usually hairy; heads globular, very large and many-fld. W. Austral. B.M. 4543 (as *P. macrocephala*).

BB. Lvs. not penniveined or very obscurely so.

c. Color of involucrel lvs. green.

d. Fls. white.

7. *glauca*, R. Br. (*P. humilis*, Lindl., not R. Br. *P. intermedia*, Lindl.). Erect, much branched, $\frac{1}{2}$ – $1\frac{1}{2}$ ft. high, glabrous below: lvs. opposite, ovate to oblong-lanceolate or almost linear, small and short; involucrel lvs. usually 4, shorter than fls.: heads globular, not many-fld., the fls. silky-hairy, white. Austral. and Tasmania. L.B.C. 17:1611. B.R. 1268, 1439.

8. *linifolia*, Smith (*P. filamentosa*, Rudge. *P. involucreata*, Banks. *P. paludosa*, R. Br.). Erect, 1–3 ft. high: branches slender, bark ferruginous, not very leafy: lvs. opposite, very short-petioled, linear-lanceolate to linear or oblong; involucrel lvs. 4, nearly as long as fls.: heads terminal, globular, erect, bearing white fls. Austral., Tasmania. B.M. 891. L.B.C. 17:1668.

9. *graciliflora*, Hook. Erect, slender, $2\frac{1}{2}$ ft. high: lvs. lanceolate, dotted above; involucrel lvs. 6, shorter than fls.: fls. long, slender, glabrous.—Very similar to *P. sylvestris*, and described as the same in Fl. Austral.: distinguished from it by narrower lvs. dotted above, and more slender pure white fls. B.M. 3288.

10. *arenaria*, A. Cunn. Small, erect shrub, dichotomously branched, to $2\frac{1}{2}$ ft.: lvs. opposite, ovate, obscurely downy above, silky hairy beneath; involucrel lvs. not different from st.-lvs.: fls. silky on outside, white; anthers and style not protruded beyond perianth-tube: heads few-fld. and sessile. New Zeal. B.M. 3270.

DD. Fls. mostly rose-colored (varying to whitish and bluish).

11. *rosea*, R. Br. Erect, small: branches sparsely leafy: lvs. opposite, linear-lanceolate or linear, glabrous both sides, margins revolute; involucrel lvs. 4, as long as fls., ciliate on margins: fls. pink or whitish, with long spreading hairs on lower portion of tube, silky on upper portion. W. Austral.—Very closely allied to *P. ferruginea*, but fls. larger and bracts more acuminate. B.M. 1458; 3721 (as *P. Hendersoni*). L.B.C. 1:88.

12. *sylvestris*, R. Br. Shrub, 2–3 ft. high, copiously branched: lvs. opposite, lanceolate or oblong-lanceolate, glaucous; involucrel lvs. 4–6, smaller than st.-lvs., shorter than fls.: fls. quite glabrous, bluish, in globular heads; stamens and style very much protruded: heads large and many-fld. W. Austral. B.M. 3276. B.R. 1582. L.B.C. 20:1965.

DDD. Fls. white and pink in same head.

13. *nivea*, Labill. (*P. incana*, R. Br.). Erect, bushy or straggling, 6 ft. or more high: branches and under

side of the lvs. white, with a dense tomentum: lvs. ovate or orbicular, glabrous above; involucrel lvs. 4–6, larger than st.-lvs.: fls. white or pink, tomentose or silky: heads globular, terminal, many-fld. Tasmania. B.R. 24:24. F.C. 1:9.

cc. Color of involucrel lvs. pink or red, or tinged only at margin.

14. *ferruginea*, Labill. (*P. decussata*, R. Br. *P. diosmifolia*, Lodd. *Heterolæna decussata*, C. A. Mey.). Short much-branched shrub, 1–3 ft. high: lvs. opposite and usually crowded, ovate or oblong, firm, with margins revolute; involucrel lvs. 4, orbicular, glabrous, shorter than the fls.: heads terminal, globular, rose-colored; fls. hairy, lower portion hispid, upper silky. W. Austral. L.B.C. 13:1283; 18:1708. B.M. 8574.

15. *spectabilis*, Lindl. Erect, 3–4 ft. high, glabrous: lvs. crowded, mostly opposite, linear-oblong or lanceolate; involucrel lvs. 4–6, ovate or ovate-lanceolate, half as long to nearly as long as the fls., usually tinged only at margins: fls. white after expansion, hairy outside: heads very large, globular, many-fld. W. Austral. B.R. 27:33. B.M. 3950. R.B. 26:157. G.W. 3, 414. F.E. 16:610.—A very handsome, showy plant, now probably the most popular species.

16. *spathulata*, Labill (*P. cernua*, R. Br.). Much branched, 2–3 ft. high: lvs. linear to linear-oblong; involucrel lvs. ovate, glabrous, sometimes not colored: fls. silky hairy, much resembling *P. linifolia*: heads large, globular, many-fld. and nodding. Austral., Tasmania. F.C. 2:72. ARNOLD V. STUBENRAUCH. L. H. B.†

PIMÉNTA (from the Spanish *pimento*, allspice). *Myrtaceæ*. Highly aromatic trees, one species of which is the allspice.

Leaves large, leathery, feather-veined, long-stalked, black-dotted beneath: fls. numerous, small, white; borne in terminal or axillary, trichotomous cymes; calyx-tube top-shaped; petals 4–5; stamens numerous: drupe 1–2-seeded.—Five or six species, native of Trop. Amer. As a genus *Pimenta* is distinguished from its near allies (*Eugenia*, *Myrtus*) by the circular or spiral embryo and the 2-celled ovary with 1–6 ovules pendulous from the apex of each cell.

2949. Allspice.—*Pimenta officinalis*. ($\times \frac{1}{2}$)

Allspice is the unripe berry of *P. officinalis*, which is gathered and dried in the sun. Its name comes from the idea that allspice combines the flavors of clove, cinnamon, and nutmeg. Allspice is common in the wild in Jamaica, inhabiting limestone soil. It is more extensively cultivated or run wild in Jamaica than anywhere else. It is cultivated up to 4,000 feet. The plant is not

2950. Flowers of allspice. (×2)

offered in the American trade, but there seems no reason why it could not be cultivated in Porto Rico.

officinalis, Berg. (*Eugenia Pimenta*, DC.). ALLSPICE. PIMENTO. Figs. 2949, 2950. Distinguished from the other species by the oblong lvs., 4-lobed calyx and globose drupe. Tree, 30-40 ft. high; lvs. 2-6 in. long; petiole $\frac{1}{2}$ in. long; fls. 3 lines long; drupe 3 lines thick. Cuba, Jamaica, Mex., Cent. Amer. B.M. 1236 (as *Myrtus Pimenta* var. *longifolia*).

P. acris, Kostel., the bayberry or bay-rum tree is by some separated in the genus *Amomis* (*A. caryophyllata*, Krug & Urb.), a shrub or small tree in the W. Indies, Venezuela, and Guiana, from the dried lvs. of which (and probably also from other myrtaceous plants) the bay oil or oil of myrica is distilled; bark separating in shreds or plates; lvs. shining above, very aromatic.

L. H. B.

PIMPERNELL: *Anagallis*.

PIMPINÉLLA (possibly from Latin *bipinnula*, bipinnate). *Umbelliferae*. About 75 species of herbs, one of which has been described under *Anise*. *P. integerrima*, Gray (see *Tænidia*), has been offered by one dealer in hardy native plants. It differs from *Anise* in being a perennial plant with lvs. 2-3-ternate and segms. entire. B.B. 2:526. *P. major*, Huds. (*P. magna*, Linn.). Sts. 1-2 ft., angularly striate; lvs. pinnate, lfts. all ovate-serrate, somewhat cut, the terminal one 3-lobed. Eu. Probably not in cult., but a form listed as *P. magna rosea*, Hort., with rose-colored fls. is cult. in England as a border and rock-work plant.

PINÁNGA (Malay name). *Palmaceæ*, tribe *Areceæ*. Slender spineless bamboo-like palms from India and the Malay Archipelago.

Stems erect; lvs. terminal, unequally lobed or pin-natisect, or simple and bifid at the apex; segms. plicate, many-nerved, the lower ones acuminate, the upper confluent, the margins not thickened, recurving at the base; rachis acute above, convex below; petiole convex above; sheath elongated; spadix usually small, very simple; peduncle short; branches in groups; spathe 1, symmetrical, swollen or compressed and 2-winged; fls. rather small, the staminate one on each side of a pistillate, thus differing from *Areca* in which the pistillate fls. are solitary; fr. ovoid or elliptical, orange or red, with a membranous husk.—About 40-50 species. For cult., see *Palms*.

Kühlii, Blume. Fig. 2951. Sts. tufted, 20-30 ft. high, slender; lvs. 3-4 ft.; lfts. many, 1-2 ft., falcate-linear to linear-lanceolate, finely acuminate, strongly 2-3-ribbed, upper confluent; petiole variable in length, somewhat scurfy; fr. $\frac{1}{2}$ in. long, shortly apiculate. Sumatra, Java. G.C. III. 31:104. G.W. 12, p. 209. Known also as *Ptychosperma* and *Seaforthia Kuhlîi*.

2951. *Pinanga Kuhlîi*.

gracilis, Blume (*Arèca gracilis*, Roxbg.). Sts. 6-20 ft. high, 3-4 lines diam., thickening upward, usually gregarious; lvs. 3-4 ft. long, sparingly pinnate; petiole and sheaths scurfy; lfts. inserted by a very broad base, 1 ft. or more long, the lower ones 2-3-ribbed, finely acuminate, the upper 3-5 in. wide, many-ribbed; fr. $\frac{1}{2}$ in. long, scarlet or orange, smooth, tapering to the tip. Himalayas, Burma.

P. maculata, Porte. A dwarf slender palm with apparently permanently variegated lvs.: lvs. elliptic, bifid nearly to the middle; spadix below the lvs., recurved; fls. showy, scarlet. Philippine Isls. B.M. 8011. Not in cult. in Amer.—*P. malaiàna*, Scheff. St. slender, 8-12 ft. high; lvs. 5-8 ft. long; lfts. numerous, linear acuminate; spadix 6 in. long, blood-red in fr.: fr. 1-1 $\frac{1}{2}$ in. long, blackish purple. Malaya.—*P. Michholtzii*, Hort. Sander is a plant exhibited at Ghent in 1908, from Sumatra. G.C. III. 43:259.—*P. ternatensis*, Scheff. (*Areca gigantea*, Hort.) Lvs. 12 ft. long, with 30-40 lanceolate segms., the largest 3 ft. long; branches of spadix spirally disposed. Ternate Isl.

N. TAYLOR.†

PINCKNÉYA (Charles Cotesworth Pinckney, of South Carolina, 1746-1825, distinguished statesman and general of the American Revolution). *Rubiaceæ*. This includes the fever tree or Georgia bark, a tall shrub or small tree with fls. in large terminal or axillary cymes, native to the marshy banks of streams in the pine barrens from S. C. to Fla. Its showy fl.-cluster attains a breadth of 4 in. and depth of 3 in., with as many as 20 fls., each 1 in. long, tubular, white, speckled red, with 5 revolute lobes. But the distinctive feature of the fever tree, both botanically and horticulturally, is the presence of 5 or more large showy colored floral lvs. These are 2 in. long, 1-1 $\frac{3}{4}$ in. wide, oval or roundish, acute, narrowed at the base, and peach-yellow margined with rosy red. The interesting feature of these floral lvs. is that they are not bracts, but modifications of one of the calyx-lobes, which are normally small and awl-shaped. Only one other species of this genus is described, *P. ionantha* from Colombia. The fever tree has been cult. in Eu. under glass, but it is rarely successfully cult. in Amer.

pubens, Michx. GEORGIA BARK. FEVER TREE. BITTER BARK. Attains 25 ft.: lvs. oval or oblong, acute, 4 x 1 $\frac{1}{2}$ in.; midrib rosy; calyx 5-lobed; lobes deciduous or one of them in the outer fls. often transformed into

a showy floral lf.; corolla hairy; stamens 5, exserted, stigma obtuse; caps. globose, papery, 2-celled; seeds numerous, in 2 rows, horizontal, winged. F.S. 19:1937. S.S. 5:227, 228.—*P. pubens* grows in low marshy woods and on borders of swamps. It thrives best when shaded by other trees. Seedlings require very rich moist soil and should always be grown under shade. They are difficult to keep alive if exposed to direct sunlight until 4 or 5 feet high; then give partial shade.

P. J. BERCKMANS and
WILHELM MILLER.

PINE. What the apple is among the fruits, what the oak is among the broad-leaved trees of the temperate zone, the pines represent among the conifers, excelling all other genera in this most important family in number of species, in fields of distribution, in extent of area occupied, in usefulness and importance to the human race. No other trees of the temperate zone have contributed so much to the building up of civilization, and no other, it may be predicted, will continue longer to fill

the important place in the household of civilized men; for not only do they furnish in a number of species the most satisfactory qualities of wood for structural purposes, but their frugality in regard to soil conditions will preserve them a place as wood-producers in many of the poor sites, when the lands fit for agricultural use have all been turned over to food-production.

Among the seventy or more well-distinguished species—over 600 species and varieties of *Pinus* have been described—all inhabitants of the northern hemisphere, ranging from the arctics through plains and mountains to near the equator, occurring in the tropics at least on high mountains, a variety of adaptation, of form, of usefulness, may be found to satisfy every requirement; and since more than half the number of species (about forty) are indigenous to North America or the United States, it is hardly necessary to go out of this general region for plant material.

For economic importance, as well as for a combination of points of excellence in all directions, ornamental as well as useful, rapidity and quantity of production and adaptability to climate and soil, the chief place belongs to the white pine (*P. Strobus*), and next in importance stands the longleaf pine (*P. palustris*) of the southern states. The red pine (*P. resinosa*), the shortleaf (*P. echinata*), the Loblolly (*P. Tæda*), with the Cuban pine (*P. caribæa*), add their stores to the enormous quantities furnished annually by the first and second. In the western mountains the bull pine (*P. ponderosa*), the sugar pine (*P. Lambertiana*), and the silver pine (*P. monticola*) are very large timber pines; and in Mexico *P. Ayacahuite* replaces the white pine, and *P. arizonica* and *P. montezumæ* are the important yellow pines. In the Philippine Archipelago one species, *P. insularis*, forms important mountain forests. In Europe the Scotch pine (*P. sylvestris*) furnishes the bulk of supplies, with *P. nigra* in the more southern countries. In Japan and northern China *P. densiflora* and *P. Thunbergii* and in the Himalayas *P. excelsa* and *P. longifolia* are the important species.

Besides the timber, several of the species furnish from their resinous contents naval stores, turpentine, tar, and pitch, the bulk of which is now still derived from the native longleaf pine. Pine wool is made from the leaves of this and other species, essential oils are distilled from leaves and young shoots and used medicinally, and the seeds of the nut pines are used for food and flavors. While the economic importance of the genus can hardly be overrated, the ornamental value is undoubtedly less than that of other genera like the spruces and firs. Nevertheless, at least interest and picturesqueness, if not beauty and symmetry of form, attach to a large number of species.

Choice of material for planting with such a wealth of species is difficult; yet climatic limitations reduce the number that may be grown within each climatic zone, and further assistance in the choice may be found in the fact that the botanical division of the species into three groups; viz., white pines, yellow pines (so called from the color of the wood), and nut pines, denotes at the same time differences of habit and form.

In no other group, perhaps, is it so necessary to keep in mind that form and habit change through the different periods of life from the juvenile through the adolescent to the virile and senile stages of development; while symmetrical and pleasing in their youth and grand or picturesque in their age, in their intermediate stages the trees may be straggling and unsightly. Starting in its youth with the pyramidal aspiring habit of all the conifers, the shaft dominating over the branch system and the latter surrounding the former in regular whorls, later on the symmetry is disturbed and finally the towering old pine may have its bole split up into many stout branches and the crown may have broadened and flattened or rounded off in the umbrella-like fashion which the stone pine (*P. Pinea*) exhibits so strikingly

in the Italian landscape. This flattening of crown is characteristic of most yellow pines, while the pignons or nut pines have a tendency to the broom-like or apple-tree appearance. Of the eastern species, the white pines alone preserve to some extent the conical habit of the crown in imitation of the spruces with more or less symmetrical horizontally spreading branches, which render them pleasing objects throughout all periods of life. On the Pacific Coast a number of species preserve the conical form.

In the choice and combination of plant material it should be kept in mind that the pines are essentially light-needing species, hence do not bear overtopping or crowding unless they have a chance by their rapid growth in height to escape from the pressure of their shade-making neighbors; the white pines, especially *P. Strobus* with its denser foliage, are more tolerant of shade than others; the dwarf *P. montana* is also tolerably shade-enduring.

In each of the three groups there are rapid growers (in height) and slow growers, although all are slow during the first two to seven years.

The common white pine (*P. Strobus*) and the Cuban pine (*P. caribæa*), with the European, Scotch, and Austrian pines, are good examples of the first class, making under favorable conditions annual shoots of 1 to 2 feet for a number of years; while the Swiss stone pine (*P. Cembra*) and other pines of high altitudes, like *P. flexilis* and *P. albicaulis*, are examples of slow growers. There are persistent growers reaching great heights, and laggards, remaining dwarfs or medium-sized trees; again the king of pines, the common white pine, and its giant congener the sugar pine, with the bull pine in favorable situations, take first rank, the first with a maximum height of 160 feet and more, the last with over 200 feet, while many of the so-called scrub pines, like *P. virginiana*, *P. serotina*, *P. Banksiana*, the Alpine white pines, *P. flexilis*, *P. aristata*, *P. Peuce*, *P. pungens*, *P. densiflora*, and most nut pines reach rarely over 40 feet; some, like *P. koraiensis*, *P. Bungeana*, *P. montana*, with several of the nurserymen's varieties, remain actually dwarfs and maintain a compact bush-like appearance for a long time.

In regard to foliage, quite a large variety can be secured. For grace and elegance nothing better again than the five-needled silver-lined white pine can be suggested, although *P. excelsa* from the Himalayas, with its slenderer and longer branches and more drooping foliage, and the dwarfs *P. Peuce* from Macedonia and *P. koraiensis*, with their denser and more compact crowns, and some others of the white pine tribe, may vie with it. Among the yellow pines, the native almost entirely overlooked, *P. glabra*, deserves mention in this connection, where the climate permits its use, as well as the interesting sand pine, *P. clausa*.

For richness, fulness, and vigor of foliage, the red pine (*P. resinosa*) outranks even the much-planted more somber Austrian pine, and for interest in development nothing can compete with the longleaf pine (*P. palustris*). With its needles, which in young specimens exceed a foot in length, surrounding in dense graceful tufts the big silvery buds at the tip of the candelabra-like branches, *P. palustris* offers a most striking appearance. Unfortunately, it is not adapted for planting north of 32°.

The thin, grayish, short foliage of the frugal Bankian pine and of several other of the scrub pines, and the stouter, also grayish, foliage of the Scotch pine, make a pleasing color contrast against the somber dark background of spruces and firs, while the short stiff needles of the nut pine, *P. edulis*, and the interesting one-needle pine (*P. monophylla*) resemble the spruce foliage. Color of bark varying in species from silvery gray through red and yellow tints to almost black, and character of size of cones from the diminutive globose forms of *P. contorta* to the long pendulous cones of the sugar

pine, 2 feet in length, and the hooked, ponderous cones of *P. Torreyana* and *P. Sabiniana*, may also influence choice of material.

With wide range of distribution and hence adaptiveness as far as climate is concerned, we have the short-leaf pine (*P. echinata*), which is found from Massachusetts to Texas, and in the West the bull pine (*P. ponderosa*), which ranges from the moist Pacific Coast in Washington to the dry slopes of Arizona. In Europe, the Scotch pine comes nearest to such wide distribution. Besides the native northern species, there have been found hardy in the northeastern states the Scotch and Austrian pines, *P. Bungeana*, *P. Cembra*, *P. koraiensis*, *P. montana*, *P. Thunbergii*, while the Mexican pines and those of southern Asia will endure only the light frosts of the southern states. Yet in the parks of Washington, D. C., the following pines are to be found: *P. Strobilus*, *P. Cembra*, *P. excelsa*, *P. Lambertiana*, *P. Ayacahuite*, *P. koraiensis*, *P. palustris*, *P. Tæda*, *P. ponderosa*, *P. rigida*, *P. nigra*, *P. glabra*, *P. virginiana*, *P. echinata*, *P. montana*, *P. Pinaster*, *P. edulis*, *P. pungens*, *P. sylvestris*, *P. Massoniana*; and the probability is that most of the other species could find a place there to live if not to thrive.

The list of species hardy in the Arnold Arboretum (Boston) comprises the following:

1. Thriving well.

Banksiana.	Lambertiana.	resinosa.
Bungeana.	montana.	rigida.
Cembra.	monticola.	Strobilus.
densiflora.	nigra.	sylvestris.
echinata.	parviflora.	Thunbergii.
Jeffreyi.	Peuce.	virginiana.
koraiensis.	pungens.	

P. excelsa and *P. ponderosa pendula* thrive well in a sheltered place, but are probably not quite hardy here.

2. Hardy, but not of promising growth.

aristata.	flexilis.
contorta var. Murrayana.	monophylla.
edulis.	

In the interior middle states the number which would stand the extremes of drought and cold would probably be reduced; a partial list found in the Missouri Botanical Garden is given below:

The best are given first. All of the later ones on the list die out sooner or later, as the city smoke is very detrimental to conifers. None does very well on that account.

Mughus (Pumilio).	} best three.	virginiana.
austriaca.		resinosa.
Strobilus.		nigra.
Cembra.		sylvestris.
rigida.		ponderosa.

For seaside planting, *P. rigida* has shown itself most fit, and of foreigners in proper climate, *P. Pinaster* and *P. halepensis*, while *P. contorta* on the northwest coast and the frugal *P. radiata* on the southwest coast are the seacoast trees *par excellence*.

The pines are essentially inhabitants of the poor sandy soils and dry situations, their stout root-system enabling them to seek the scanty water-supplies where other species find it difficult. Some, like the white pine, are adapted to a variety of soil conditions, but only a few can endure a surplus of water: *P. resinosa* will follow the white cedar into the swamp and thrive there as well as with the Banksian pine on the poorest gravels; *P. rigida* is at home both in wet and dry places; the Scotch pine of the Baltic sand plains may be found in the peat-bogs, but only eking out a miserable existence, while *P. Tæda*, the old field pine, makes magnificent trees in the southern swamp, and with its slow growth under such conditions an excellent timber. *P. contorta* and *P. serotina* also are indifferent to water conditions at the root; so is the Cuban pine, but *P. palus-*

tris belies its name, for it is only very rarely found in poorly drained places and does not thrive there.

The propagation of pines does not offer any difficulties. The seed usually has a high germination percentage in most species if kept dry and cool, and it retains vitality for several years, deteriorating of course somewhat from year to year. To avoid deterioration in transoceanic shipments, packing in charcoal dust has been found very serviceable. While most of the pine seeds sprout readily, the white pine, with some others, has the bad habit of lying over for one year in part, unless treated to a hot-water bath for twenty-four hours before sowing; or perhaps by sowing in autumn immediately after coming out of the cone, which is during the first two weeks of September. The seeds should be sown in light mold early, rather thinly to permit a good root-system to develop, covering them thinly according to size of seed, not over $\frac{1}{4}$ inch, which is best done by sifting sand over the seed with a sieve. During the first year special care is necessary to regulate the water-supply and transpiration for the young seedlings; they need to be kept humid, not wet, but resent drought as much as a surfeit; and especially sudden changes from drought to wet are likely to produce "damping-off." To prevent too rapid transpiration, the familiar lath screens should be applied.

To prevent the formation of excessively long tap-roots which some species form, mechanical means may be adopted; but the best plan is to manure near the surface, so that fibrous roots will be formed. Such manure consists of one-third steamed bone-meal and two-thirds ammonia superphosphate. Root-pruning and transplanting in nursery rows when one or two years old is practised to secure a stocky root-system. In Germany one-year-old Scotch pines are planted by the million for forest purposes, but for ornamental purposes older plants are to be used; yet it is safest not to use them older than three or four years for permanent situations. In the third year usually the first branching occurs, indicating that the root-system is now well established.

In transplanting, the utmost care must be taken not to expose the roots to drying influences, a thin loam puddle answering best to keep them moist. While transplanting can be done at any time of the year, it is safest to do so in early spring, except when a droughty season is likely to follow, in which case fall planting is to be preferred.

A large number of nurserymen's varieties, dwarf and pendulous, varicolored, and the like, have been developed, especially from *P. sylvestris* and *P. Strobilus*. The most interesting freaks perhaps are those bushy forms derived from *P. canariensis* and *P. Pinea* produced by layering, in which single needles instead of the usual bundles of two in one sheath are produced, imitating the primary single needles of seedlings. The manner in which nurserymen's varieties are propagated by grafts or cuttings is discussed under *Pinus*.

According to the nature of the pines, if there is choice of location possible, the well-drained situations, even dry ones, should be reserved for them. They belong, with few exceptions, to the hilltops not the bottoms, to the sands not clay soils, and will stand southern exposures better than the spruces.

Pines are frugal by nature, and can stand poverty better than surfeit,—nevertheless they respond best to medium conditions, namely, a mellow surface and well-drained deep loamy sand, not too rich in organic matter and loose enough to permit the natural development of the heavy tap-root system. Under such conditions, the peculiar rich foliage gives most satisfaction and the rank luxuriant growth which leads to poor form is checked; disease from fungi is obviated; the cottony scale (almost the only enemy of the white pine) is more readily fought, and injuries from caterpillars and beetles are more easily repaired. Lately,

two enemies of the white pine have developed which require attention. The one, a fungous disease, seems to be an importation from Germany, the white pine blister rust (*Peridermium strobi*), which attacks young trees and young foliage of the white pine tribe. It needs gooseberry and currant as intermediary host plants. The other pest is the white pine weevil, which works in the young shoots and disfigures the tree by inducing repeatedly new leaders to develop.

To prune evergreens, and especially pines, requires an artist, or else the result will be malformation: the best plan is to correct form by breaking out the center bud from such shoots as project beyond proper limits; thereby also a more compact growth is induced, which in the pines with their open habit is desirable. If it becomes necessary to prune the branches, the cut must remove also the bolster at the base of the branch; the resinous exudation will prevent decay, and the cambium soon covers the scar if the cut has been made properly. For hedge planting the pines furnish no specially desirable material, being light-needing and therefore thinning out soon in the interior; yet the white pine will stand as a hedge for a considerable time and also the dwarf *P. montana*. Perhaps some others may answer the purpose.

For the botany of the pines, see *Pinus*.

B. E. FERNOW.

PINEAPPLE. The pineapple (see *Ananas*) is indigenous to America. It produces one of the most delicious fruits now regularly on the markets. The finest qualities are developed when the fruit is permitted to ripen naturally upon the plant. For distant markets the crop has to be gathered in varying degrees of unripeness to suit the time required in transit.

The year 1850 seems to be the earliest date at which pineapple-growing was attempted in the United States. This attempt was made near St. Augustine, Florida, according to Taylor. In 1860, planting was begun on

2952. Cuttings of pineapple, ready to be planted.

the Keys, but the want of facilities for rapid transportation and the more favored Cuban and Porto Rican plantations, made the development slow. In 1897, about \$15,000 worth was imported from the Hawaiian Islands.

Good pineapple land may usually be obtained for \$25 to \$100 an acre, the higher-priced land being in favored locations at railway stations and near settlements. The cost of clearing and preparing varies from \$20 to \$80 an acre, according to the cost of labor and the character of the growth on the land.

From 8,000 to 15,000 plants are needed to the acre, varying with the variety and the notion of the planter.

The price of plants in the field varies from \$3 the 1,000 for Red Spanish to \$350 the 1,000 for the finer varieties. The cost of cultivating and fertilizing an acre for one year varies from about \$20 to \$150. It requires about eighteen months from the time of setting out to the maturing of the first crop, which yields 50 to 350 crates to the acre. Under favorable circumstances the second crop may be double that of the first. By careful attention the plantation may be continued for eight or ten years without resetting; the second or third crop frequently bears the maximum amount of fruit.

When a common variety is planted, the returns are mainly from the sale of fruit, but with fancy varieties the sale of plants constitutes the main source of returns. Four hundred dollars or more an acre has been realized frequently for a crop of the commonest varieties; in this case increase in plants cannot be considered as of much value. The value of a crop of fancy fruit is about double that of the common, and \$1,000 worth of plants may be sold without detriment to the plantation, if it is a variety that is in demand. From this must be subtracted the cost of transporting to the markets, which varies more or less with the distance the fruit is hauled. This cost varies with the quantity shipped, from \$20 to \$80 or more an acre.

The pineapple thrives in a variety of soils, but whatever its texture it must not be moist or wet. The pineapple plant will survive air-drying for months, but decays rapidly in a moist atmosphere. The greatest acreage is located upon dry sandy land, formerly overgrown with spruce-pine (*Pinus clausa*) or a mixture of spruce-pine and hardwood. Chemical analyses of the soil from pineapple fields show an exceedingly small fraction of a per cent of the essential fertilizer ingredients present. A physical analysis shows that the water-content is very low. A considerable acreage is planted on the Florida Keys. Here there is only a small amount of leaf-mold, often not more than an inch on the average, covering a coralline rock. But for the fact that pineapples actually grow and make crops on such soil it would seem entirely incredible.

With conditions of soil as described above, it is imperative to fertilize, and under the existing conditions in the pineapple belt there is no other remedy than the addition of commercial fertilizers, and nothing better. While much is still to be learned about fertilizing this crop, it is fairly well established that for pineapples on spruce-pine land, dried blood, ground bone, and nitrate of soda are good sources of nitrogen; that low-grade sulfate of potash, carbonate of potash and high-grade sulfate of potash are good sources of potash; that acid phosphate should be used in small quantities only or avoided, using pulverized bone instead. A good plan for fertilizing is to drop a small handful of cottonseed meal into the bud immediately after setting out. In October, apply about 600 pounds blood and bone and 400 pounds low-grade sulfate of potash (not kainit) to the acre, or the equivalent of these fertilizers in some of the forms mentioned above. A second application may be made the following February; at this time the amount may be increased 10 to 25 per cent, according to the growth the plants have made. A third application may be made in June or July; and if the plants have grown vigorously a still further increase in amount may be made. A fourth application may be made in October, increasing the amount if the plants have grown vigorously. The succeeding applications may be made at the time suggested above, and the increasing and decreasing of the amounts may be determined by the progress of the plants. As the average spruce-pine pineapple land is not sufficiently fertile to grow a full crop of pineapples, much more depends upon proper fertilizing than any other one operation.

This plant is propagated by means of crowns, slips suckers, and ratoons. The crown is the leafy part

of the fruit as found in the market. Just below the fruit small plants form, which are left in the field when the fruit is gathered; these are known as slips. In the axils of the leaves buds occur; those that develop near the ground make strong plants in a few months and are known as suckers. (Fig. 2952, after Wester.) A strong plant will mature an "apple" in June and produce two to five suckers by the middle of September. Buds that

2953. The Queen pineapple.

develop from an underground part and form a root-system independent of the parent plant are known as ratoons. Crowns are not planted extensively, as they remain on the fruit when marketed. Good strong suckers are usually employed for planting out. Ratoons are left in the field to replace the plants which have borne a crop, but they are not sufficiently numerous to make a full stand; hence some of the suckers must be left also. Slips require a year longer than suckers to mature a crop. According to Webber, it requires ten to twelve years to mature a plant from seed. Plants are raised from seed only for breeding purposes.

If spruce-pine land is prepared it is cleared of all stumps, wood, roots, and any other organic material, and is plowed deep and leveled off smooth. The fields are then laid off in beds of six or eight rows wide, depending on the variety. The beds should be narrow enough to permit fertilizing and working with a scuffle-hoe without entering the beds, as breaking the leaves is very detrimental. For Red Spanish the rows are made 18 to 20 inches apart; for Queens, 20 to 22 inches; for Porto Ricos, 30 to 36 inches. They are usually placed in checks of about the same distances.

The methods employed on the Keys are quite different. The land is cleared by cutting off the trees, shrubs, and the like, which are allowed to dry and are then burned. The plants are then set out with a grubbing-hoe; they must be set out irregularly, as the rocky soil does not furnish root-hold everywhere. Such fields become exhausted in a few years and have to be abandoned.

Cultivation consists in running over the ground with a scuffle-hoe. When the plantation is set out in beds the handle of the hoe is long enough to permit cultivating to the middle without the laborer entering the bed. Only about an inch of the surface soil is agitated, usually immediately after the fertilizer has been applied. Weeds are not troublesome, excepting in fields that have been cultivated a long time. Under sheds tillage is more frequent and appears to be more necessary. On the Keys no tillage is possible, but tall-growing weeds and such ligneous plants as may spring up are cut off. In all of the work among pineapple

plants the greatest care should be exercised to avoid breaking the leaves, which are very brittle.

The fruit is picked a week before it would mature. It is packed at once into barrel (12 by 20 by 36 inches) and half-barrel (12 by 10 by 36 inches) crates, usually in the latter, the different sizes being packed in separate crates and designated as 18's, 24's, 30's, 36's, 42's, 48's, and 54's, according to the number required for a half-barrel crate. The fruit must be handled without being bruised and packed firmly to prevent its abrasion in transit. To protect the fruit each one is wrapped separately in brown paper.

Since the propagation is accomplished by means of offsets, the varieties are fairly stable and rather definitely marked. The variety most extensively grown is called Red Spanish, Spanish, or Reds. It has a medium-sized apple, and is a hardy plant. Abachi (Abakka), Blood, Queen (Fig. 2953), Sugar Loaf, Envile (Fig. 2954), and White Antigua are varieties that produce medium-sized apples of excellent quality. Black Jamaica, Black Prince, and Prince Albert produce large fruits or apples of excellent quality. Smooth Cayenne and Porto Rico produce large apples of good quality, those of the latter being of greater size. Other varieties are grown more or less extensively, and there are different names for these varieties, but the foregoing have been officially recognized by the Florida State Horticultural Society.

It has been found very advantageous to build a shelter for "pines" in the winter a shed protects the plants from too great radiation of heat, and in the summer it reduces the intensity of the sun. The original object of the shelter was to protect the plants from frosts and freezes. Pineapple plants freeze at 32° F. This degree of cold does not kill the heart of the plant, but only the larger part of the leaves. Pines under sheds have passed through a temperature of 25° F. without serious injury. The roof of a shed is usually flat, or undulating with the surface of the land. The height varies with the desires of the individual, but is usually about 8 feet above the ground.

In Fig. 2955 the roof is slightly less than 7 feet from the ground. The stringers running crosswise in the figure are $1\frac{1}{2}$ " by 3" by 21'; those running lengthwise are $1\frac{1}{2}$ " by $1\frac{1}{2}$ " by 15'. The material for the roof is cypress plastering lath of usual length and width. The stringers running lengthwise are 46 inches apart. The openings between the lath are just the width of a lath. The amount of lumber needed (to the acre) is about as follows:

424 posts (352 for roof, 72 for sides) 4" x 4" x 8'.
160 pieces $1\frac{1}{2}$ " x 3" x 20'.
960 pieces (840 for roof, 120 for sides) $1\frac{1}{2}$ " x $1\frac{1}{2}$ " x 15'.
80,000 lath (75,000 for roof, 5,000 for sides) $\frac{3}{8}$ " x 1" x 4'.

It requires about 9,000 feet of lumber for the above material exclusive of the lath. All lumber must be first-class and free from knots. This can still be reduced by about 2,500 feet by using wire in place of the $1\frac{1}{2}$ " by $1\frac{1}{2}$ " by 15' and weaving the lath in this. Under the most favorable circumstances such a shed can be erected for \$450 an acre, but this is about the cheapest and lightest form that will withstand the elements.

The following diseases and insects attack pineapples:

2954. The Envile pineapple.

(1) Heart-rot; bitter-heart: The cause of this disease is not known, but it seems to be more prevalent in a rainy season than in a dry one. It manifests itself by the portion around the heart taking on a water-soaked appearance. This condition progresses outward until the whole apple is involved. It is not necessarily accompanied by rotting, although this usually follows. The whole apple becomes bitter, even before it is entirely involved. When this disease is present in a field, the fruit should be marketed as soon as possible, that the apples may be consumed before becoming badly affected. (2) Sanding: This disorder occurs immediately after setting out, especially if a long dry spell occurs at this time. It is produced by sand being blown into and filling the bud of plants. Immediately after setting out, drop into the bud a small handful of cottonseed-meal, or the same amount of a mixture of one part ground tobacco stems and three or four parts cottonseed-meal. This soon forms a firm plug in the

2955. Pineapple shed in Florida.

bud, keeping out sand but not interfering with growth. Blood and bone, or blood, bone and tankage, may also be used. (3) Spike; longleaf: This disease manifests itself by the leaves failing to expand at the base, thus giving the plant a contracted appearance. The outer portion of the leaf spreads from the center of the plant, but usually fails to take on a broad flat healthy appearance. Experiments have proved that this disease may be produced by improper use of commercial fertilizers, although the disease has occurred where no fertilizer had been used. Abundant evidence is at hand to show that the disease is not due to an organic agent but rather to untoward condition in the soil. Change the fertilizer, avoiding acid phosphate, kainit, and cottonseed-meal in large quantities, and give protection as by a pineapple shed (spike is a rare thing under sheds). (4) Blight; wilt: This disease occurs in a sporadic manner, usually without any apparent regularity. In some varieties the first intimation of blight is by the outer end of the leaves turning red, and later by the tips wilting. This wilting progresses until the entire plant has dried up. According to Webber the direct cause is a soil-inhabiting fungus which attacks the roots. Remove the wilted plants and set in healthy ones. If the plants are of valuable varieties trim off all diseased roots and much of the stem, together with larger leaves, and reset. It is probable that the fungus will not survive until the roots again penetrate the soil. (5) Red-spider (*Stigmæus floridanus*): This species attacks the tender white portion at the base of the leaves. The effect upon the plant is greatly out of proportion to the small amount of injury to the parts attacked. In later stages the leaves rot off at the place attacked. Drop a small handful of tobacco dust into the bud of the plants.

Subsequent rains and dews leach the tobacco and carry the solution down to the red-spiders. If they are not all dead in a week or ten days, repeat the dose. (6) Scale insect (*Diaspis bromeliæ*): This scale insect becomes troublesome in dry localities and in greenhouses. The insect usually attacks the lower surface of the leaf, but each point of attack shows through as a yellow spot or blotch on the upper surface. Spray with resin wash, resin compound, or whale-oil soap. (7) Mealy-bugs (*Dactylopius citri* and other species): These insects attack the base of the leaves just at or below the ground-level; also the bud, and when fruit matures they multiply in great numbers among the slips and in the eyes of the fruit itself. The remedy is the same as for scale insects, but it is very difficult to make the application effective. When the mealy-bugs are present before the fruit-bud forms, much good can be done by applying a large handful of tobacco dust in the axils of the lvs.

See also under *Florida*, page 2230. P. H. ROLFS.

PINEAPPLE AIR-PLANT: *Tillandsia utriculata*. P. Flower: *Eucomis punctata*.

PINE, DAMMAR: *Agathis*. P., Kauri: *Agathis*. P., Moreton Bay: *Araucaria*. P., Norfolk Island: *Araucaria*. P., Prince's: *Chimaphila*. P., Screw: *Pandanus*.

PINÉLIA: *Restrepia*.

PINÉLLIA (after Pinelli). *Aracæ*. About a half-dozen hardy perennial tuberous herbs, native to China and Japan. Foliage appearing with the fls.; lvs. 3 or pedatisect: peduncle solitary: spathe marcescent: fls. monocious in the appendiculate spadix, all fertile; perianth none; male fls. with 1 stamen; female fls. 1-sided; ovary 1-celled; ovule solitary, orthopterous.

tuberifera, Tenore. Adult lvs. 3-parted, the middle segms. $1\frac{1}{2}$ -2 times longer than wide and elliptic-oval. China.—There is a variety with narrower lf-segms. and another with lvs. cut into 5 segms.

PINGUICULA (diminutive of Latin *pinguis*, fat; referring to the succulent and greasy foliage). *Lentibulariæ*. BUTTERWORT. Small acaulescent herbs of carnivorous habits, with pretty long-spurred flowers something like a snapdragon; sometimes grown for their oddity and for the study of insectivorous habits.

Plants of moist or wet grounds, sometimes growing on damp rocks, with fibrous roots: lvs. in a basal tuft or rosette, broad and entire, soft, the upper surface usually glandular-viscid (secreting a digestive fluid) and the margins infolding when insects and other objects adhere: fls. white to purple and yellow, solitary on naked scapes which are coiled in veneration; calyx 5-lobed and somewhat 2-lipped; corolla mostly 2-lipped, ringent or more or less perispermate, with 5 spreading unequal lobes, the base extended into a sac or spur; stamens 2: fr. a 2-valved caps.—Species 30-40, in the northern hemisphere and also along the Andes to Patagonia. The species are little seen in cult., *P. caudata* and *P. lutea* being best known to growers. *Pinguicula* is one of the very few dicotyledonous plants with only 1 seed-leaf. The fls. of *pinguicula* are often reversed in position before and during anthesis.

This interesting genus is rarely seen under cultivation, except in botanic gardens. The most noteworthy species of the genus is the Mexican butterwort, *P. caudata*, both for its floral and leaf characters. A peculiar feature of the plant is that it produces two kinds of growth,—the resting type, in which the small succulent leaves are imbricated and form a small dense rosette about 1 inch in diameter; also the growing type, in which the obovate leaves when fully grown measure 3 to 4 inches long by 2 to 3 inches wide.—In February the small rosettes of *P. caudata* should be potted in the pans large enough to carry them throughout the

growing period, because they are not conveniently transplanted. Three plants may be placed in 6-inch pans, keeping them close to the side of the pan in triangular form. A good growing medium consists of two parts peat soil, one part fibrous loam and one part sand, with plenty of drainage. When in full growth, the top of the pan will be fully covered by the viscid leaves. Watering the plants from above should not be practised because of destroying the dew-like deposit on the surface of the leaves. The pans should be placed in saucers of water, and set in a light position in the warm-house; give plenty of sunshine and the plants will readily flower throughout the summer. In October place the plants in the cool end of the house to rest. The growth will gradually deteriorate until it assumes the rosettes of small succulent leaves to carry them through the resting period.—Young plants are propagated almost as readily as *echeverias*. The small rigid leaves should be carefully broken from the main stem; if not broken clean they will not reproduce young plants. These should be laid flat on sand in pans of convenient size; the top of the pan should be protected by glass or a bell-jar, to retain the moisture; place the pan in a saucer of water. In four to six weeks the young plants with the leaf attached will be sufficiently rooted to allow potting. One of the worst pests are woodlice. (G. H. Pring.)

A. Color of fls. yellow.

lutea, Walt. Exceptional by reason of its yellow fls. and nearly regular (not 2-lipped) corolla: variable in the size of all its parts, and in the obtuse tothing of the corolla-lobes: lvs. ovate to oblong-ovate: scapes 5–12 in. high; fls. $\frac{1}{2}$ – $1\frac{1}{2}$ in. long and broad; spur curved, about as long as the rest of the corolla; throat spotted and lined with red; palate very prominent and densely bearded. Low pine barrens, N. C. to Fla. and La. B.M. 7203. B.R. 126.

AA. Color of fls. purple to lilac.

B. Spur 2 or 4 times as long as remainder of the corolla.

caudata, Schlecht. (*P. orchidioides*, A. DC. *P. Bakeriana*, Hort.). Lvs. in dense rosettes when young, long and narrow; on older plants few and large, obovate and obtuse: scapes 5–7 in. high; fls. deep carmine, with lighter throat and reddish lines, attaining 2 in.; lobes all rounded except the middle one of the lower lip, which is retuse. Mex. B.M. 4231. G.C. II. 15:541. R.H. 1902:456. Gn. 23, p. 309. G. 29:181. G.W. 9, p. 482; 12, pp. 308–10. Var. *superba*, Hort. Fls. rich rosy carmine with white eye, about 2 in. long and nearly as broad.—According to W. Watson, England, *P. caudata* "is largely grown by orchid-breeders, who find it an excellent trap for the tiny midge-like fly which lays its eggs in orchid seedlings when they are very young. . . . It is a most charming little pot-plant, and has become a favorite in many gardens."

Rosei, W. Wats. Very like *P. caudata* and perhaps a form of it, but the fl. deep violet-purple, almost a blue, nearly 2 in. across and remaining fresh for weeks. Prop. from the fleshy lvs. Mex. G.C. III. 49:82.

gypsicola, Brandeg. Plant 3–4 in. high: lvs. when plant is in bloom linear from a rather broad base, about 2 in. long, revolute on margins, with viscid glandular hairs on upper surface; later or winter lvs. spatulate-oblong and cotyledon-like, in a very dense rosette: fl. purple, with a very short white tube; upper lip 2-parted into linear-oblong lobes; lower lip 3-parted into similar lobes; spur more than 1 in. long, slender, purplish, 2-toothed at tip. Mex. B.M. 8602.

BB. Spur about as long as remainder of the corolla.

C. Fls. $\frac{3}{4}$ –1 in. long and broad.

grandiflora, Lam. Scapes 3–8 in. long; fls. "blue, rarely purplish violet," according to De Candolle,

10–15 lines long, 9 lines broad (3 or 4 times longer than in *P. vulgaris*); lobes undulate; palate with 1 or 2 white spots; spur straight, a trifle shorter than the broadly funnel-shaped tube. W. Eu. G.C. III. 10:373.—According to Bentham, this is a large-fl. variety of *P. vulgaris*, with longer spur and broader lobes, which in the western part of Eu. passes into the common form.

hirtiflora, Tenore. Scapes 3–4 in. high; fls. 8 lines long and broad, lilac or rose (blue according to Tenore, and shown as purple in B.M.), with a white tube; spur straight or curved, about as long as the rest of the corolla. S. Eu. B.M. 6785. Gn. 25, p. 291. G. 11:251.—Possibly distinguished from *P. grandiflora* by the color of the tube, which is white outside and yellow in the throat. According to Burbidge there is a variety with pure white fls.

CC. Fls. $\frac{1}{2}$ in. long and broad.

vulgaris, Linn. According to Hooker, this differs from *P. hirtiflora* in the bright blue color and the retuse lobes of the corolla, as also in the less globose caps.: scapes 1–5 in. high; fls. bluish purple or violet, about 6 lines long; spur nearly straight, about 2 lines long or as long as the rest of the corolla. Wet rocks, Eu., Asia, New England, and north and westward. Gn. 57, p. 335; 69, p. 101.—Sometimes called "Labrador violet."

P. elatior, Michx., in N. C. to Fla., is a beautiful species that should be in cult.: plant 3–5 in. across and 10–12 in. tall; lvs. viscid-glandular; in pale green rosettes: fls. whitish purple, to $\frac{3}{4}$ in. broad.

WILHELM MILLER.

PINK: *Dianthus*.

L. H. B.†

PINUS (ancient Latin name). *Pinaceæ*. PINE. PINE-TREE. Ornamental trees grown for their handsome evergreen foliage and symmetrical or picturesque habit, some also for their conspicuous large cones; many species are valuable timber trees. See *Pine*.

Resinous evergreen trees with usually whorled branches, rarely shrubby: winter buds covered with

2956. Staminate cone of *Pinus rigida*. (×2)

2957. Pistillate flowers (enlarged) of Austrian pine; also, at bottom, a young pistillate cone (natural size). a, front view of two ovules; c, side view.

imbricate scales: lvs. of 2 kinds; the primary lvs. are spirally arranged and as they appear on young seedling plants and occasionally on shoots from the old wood, are green and subulate, but commonly they are reduced to small scarious bracts bearing in their axils the acicular, semi-terete or triangular secondary lvs. borne on an undeveloped branchlet in clusters from 2–5, or occasionally more, rarely reduced to 1, surrounded at the base by sheaths of 8–12 bud-scales: fls. monœcious; the

staminate ones axillary, clustered at the base of the young shoots, catkin-like, yellow, orange, or scarlet, composed of spirally arranged numerous 2-celled anthers with the connective enlarged and scale-like at the apex (Fig. 2956); pistillate lateral or subterminal, greenish or purplish, consisting of numerous spirally arranged scales each in the axil of a small bract and bearing 2 ovules inside near the base (Fig. 2957): cone subglobose to cylindric, with woody scales closely appressed before maturity and tightly inclosing the seeds, which are usually furnished with a long thin wing, but in some species are wingless or short-winged; the apex of the scales is usually more or less thickened and the exposed part, which is usually rhombic in outline and termed apophysis, is often protracted into prominent bosses or knobs; the apophysis is terminated by the umbo, usually differing in color and ending mostly in a spine or prickle. In *P. Strobus* and the allied species the apophysis is flat and thin, and bears the spineless umbo at the upper end, while in most other pines the apophysis is thickened and transversally keeled and bears the umbo in the middle. These differences belong to the most important characters in the grouping of the species:

other valuable characters are furnished by the structure of the lvs., which contain either 1 or 2 fibro-vascular bundles and usually 2 or more resin-ducts, being either external (or peripheral), i.e., situated beneath the epidermis; or medial (or parenchymatous), i.e., inclosed by the tissue of the lf.; or internal, i.e., close to the fibro-vascular bundles; some

2958. *Pinus Strobus*.

Leaf with a single fibro-vascular bundle (a), usually two external resin-ducts (b); strengthening cells (c) only beneath the epidermis; stomata (d) only on the two inner sides.

species, as *P. Armandi*, *P. resinosa*, *P. sinensis*, also *P. excelsa*, *P. Lambertiana*, *P. virginiana*, and the like, have resin-ducts in 2 positions, either external and medial or internal and medial, but such combinations are not found in all the lvs. of these species. Strengthening cells, i.e., cells with thickened walls, are mostly present beneath the epidermis and often surround the resin-ducts, sometimes also along the fibro-vascular bundles. (See Figs. 2958–2961.) The number of the fibro-vascular bundles and the position of the resin-ducts can be readily seen with a common magnifying glass in thin cross-sections made with a sharp razor from the middle of the lf. and placed on a glass plate.—About 80 species are known, distributed throughout the northern hemisphere from the arctic circle to Mex. and the W. Indies, N. Afr., and the Malayan Archipelago; in the tropical and subtropical regions they are confined to the mountains. In the following enumeration the species are grouped according to Shaw's classification. To facilitate the determination of the cult. species, a key is given to determine plants without cones, but owing to the great variability in pines this key may fail, if the plant in hand represents some uncommon variation. Good illustrations are found in Sargent, *Silva of N. America*, vol. 11; Lambert, *Description of the Genus Pinus*; Lawson, *Pinetum Britannicum*; Forbes, *Pinetum Woburnense*; Antoine, *Die Coniferen*; Clinton-Baker, *Illustrations of Conifers*, vol. I; Pardé, *Iconographie des Conifères* (in course of publication). For the horticultural varieties, see Beissner, *Nadelholzkunde*, second edition (1909), and the new edition by A. H. Kent of Veitch's *Manual of the Coniferae*. Among other important works may be mentioned E. A. Carrière's *Traité*

général des Conifères, second edition, 1867; Heinrich Mayr's *Die Waldungen von Nordamerika*, 1890; G. Engelman's *Revision of the Genus Pinus*, in *Transactions of the Academy of Science of St. Louis*, published in 1880; Maxwell T. Masters in *Journal of the*

2959. *Pinus Coulteri*.

Leaf with two fibro-vascular bundles (a); several medial resin-ducts (b); strengthening cells (c) around the resin-ducts, several layers beneath the epidermis and along the inner and outer side of the fibro-vascular bundles; stomata (d) all around.

Linnean Society, vols. 22 (1886) and 27 (1889); Conifer Conference in *Journal Royal Horticultural Society*, vol. 14 (1892); Silva Tarouca's *Unsere Freiland-Nadelhölzer* (1913); G.R. Shaw's *The Pines of Mexico* (1909) and *The Genus Pinus* (1914), both well illustrated.

The pines are usually tall trees, rarely shrubby, with spreading branches forming a pyramidal or round-topped, in old age often very picturesque head, and clothed with acicular leaves in clusters of 2–5, rarely solitary. The flowers are catkin-like, appearing in spring, the staminate yellow or purple, often conspicuous by their abundance, and the pistillate greenish or purplish, developing into subglobose to cylindric, usually brown cones, which sometimes attain 18 or more inches in length, ripening mostly not before the second or rarely the third year. The pines are among the most important timber trees of the northern hemisphere, and many of them are valuable for the decoration of parks and gardens.

Young pines are with few exceptions of more or less regular, pyramidal habit; but in old age they are often very picturesque, especially *P. Strobus*, *P. radiata*, *P. rigida*, *P. Pinea*, *P. Cembra*, *P. nigra*, *P. parviflora*, and others. Of very graceful habit, with slender branches and more or less drooping foliage, are *P. excelsa*, and the tender *P. Ayacahuite*, *P. longifolia*, and *P. canariensis*. The very large cones of some species, as *P. Lambertiana*, *P. Ayacahuite*, *P. Sabiniana*, and *P. Coulteri*, are a conspicuous ornament. Most species are of vigorous growth when young, but the foreign species usually grow rather slowly and are therefore well suited for smaller gardens, especially *P. koraiensis*, *P. Peuce*, *P. Bungeana*, *P. parviflora*; the American *P. aristata* and *P. flexilis* may also be recommended for this

2960. *Pinus palustris*.

Leaf with two fibro-vascular bundles (a); several internal resin-ducts (b), one layer of strengthening cells (c) beneath the epidermis and on the inner side of the fibro-vascular bundles; stomata (d) all around.

purpose. For planting rocky slopes *P. Banksiana*, *P. rigida*, *P. virginiana*, and some western species are valuable; and if dwarf forms are desired *P. montana* is one of the best, thriving better than any other species in shaded positions and as undergrowth in open woods.

A great number of the species are hardy North. Among the hardiest are *P. Strobus*, *P. Cembra*, *P. parviflora*, *P. Bungeana*, *P. koraiensis*, *P. rigida*, *P. Banksiana*, *P. Thunbergii*, *P. resinosa*, *P. sylvestris* and *P. montana*. The Mexican species and those from southern Asia stand only a few degrees of frost.

The pines are not very particular as to the soil, and in their native habitats they usually occupy the less fertile situations, as dry uplands and sandy plains. Some, as *P. rigida*, *P. caribæa*, and *P. Tæda*, can be grown both in dry and in swampy ground. *P. palustris* is very unhappily named, since it almost never grows in swamps. Pines are much used for the afforestation of barren sandy plains and dry rocky mountain slopes. For seaside planting *P. rigida* and the more tender *P. radiata*, *P. Pinaster*, *P. halepensis*, and *P. canariensis*

2961. *Pinus echinata*.

Leaf with two fibro-vascular bundles (a) and several medial resin-ducts (b); only one layer of strengthening cells (c) beneath the epidermis; stomata (d) all around.

are valuable; the last three species are now much planted in California, both for timber and ornament.

Pines cannot be transplanted as successfully as large plants on account of their long tap-roots, and only younger nursery-grown trees should be used for planting. As they cannot usually be taken up with a good ball of earth, it is well to immerse the roots in a loam puddle immediately after the trees are dug up.

Pines are propagated by seeds sown in spring in prepared beds or frames, or in boxes or pans; the seeds should be covered slightly with fine soil, but the larger ones about $\frac{1}{4}$ inch, and the young seedlings shaded and watered when necessary. Varieties and rarer kinds are grafted on their types or allied species, usually by veneer-grafting on potted stock in the greenhouse in winter, or in spring outdoors by cleft-grafting in the terminal bud (M.D. 1901, p. 15). Cuttings even of the dwarf forms do not root readily; the easiest to root are young shoots with primary foliage, as they sometimes appear on older branches or on the trunk.

The pines belong to the most important timber trees in their native countries; these are, in eastern North America, *P. palustris*, *P. Strobus*, and *P. echinata*; in the western states, *P. Lambertiana*, *P. monticola*, and *P. ponderosa*; in Europe, *P. sylvestris* and *P. nigra*; in eastern Asia, *P. Thunbergii* and *P. densiflora*, and in the Himalayas, *P. excelsa*. From the resinous secretions of many species, chiefly *P. palustris*, *P. caribæa*, *P. Pinaster*, *P. halepensis*, and *P. longifolia*, turpentine, tar, and pitch are obtained. An essential oil used medicinally is distilled from the leaves and young shoots of several species. Edible seeds are produced by some species, in America by *P. edulis* and *P. cembroides*; in Europe by *P. Pinea* and *P. Cembra*; in East India by *P. Gerardiana*. Mats similar to cocoa mats are manufactured from the leaves of *P. palustris*, and pine wool for stuffing mattresses is made from leaves of European and American species.

For another account of the relative value of species of *Pinus* and their culture, see *Pine*.

NO. 1. KEY TO THE SPECIES WITH THE CONES.

I. SOFT PINES (*Haploxyylon*).

Wood soft, close-grained, light-colored, the sap-wood thin and nearly white; sheaths of the lf.-clusters deciduous; lvs. with 1 fibro-vascular bundle.

- A. Umbos of scales terminal.
 B. Seeds wingless or with rudimentary wing.
 C. Margin of lvs. serrulate.
 D. Branchlets hairy: cones indehiscent.
 E. Cones ovate: branchlets brownish tomentose. 1. *Cembra*
 EE. Cones cylindric-conical: branchlets pubescent. 2. *koraiensis*
 DD. Branchlets glabrous: cones dehiscent, cylindric-conical. 3. *Armandi*
 CC. Margin of lvs. entire: cones dehiscent: lvs. stout, $1\frac{1}{2}$ -3 in. long. 4. *flexilis*
 BB. Seeds winged, with long wing, short in No. 5.
 C. Cones less than 10 in. long.
 D. Scales of cone with convex thickening.
 E. Length of cone about 2 in., shape ovate: branchlets pubescent: lvs. $\frac{3}{4}$ -1½ in. long. 5. *parviflora*
 EE. Length of cone $3\frac{1}{2}$ -10 in., shape cylindric: branchlets glabrous.
 F. Lvs. 3-4 in. long, stiff. 6. *Peuce*
 FF. Lvs. 6-8 in. long, drooping. 7. *excelsa*
 DD. Scales of cone uniformly thin.
 E. Branchlets glabrous: lvs. thin, soft. 8. *Strobus*
 EE. Branchlets at first pubescent: lvs. stiff. 9. *monticola*

- CC. Cones 10-18 in. long: branchlets pubescent.
 D. Scales of cone rounded: lvs. stout.....10. *Lambertiana*
 DD. Scales of cone with elongated and more or less recurved apex: lvs. slender.....11. *Ayacahuite*
 AA. Umbo of scales dorsal.
 B. Seeds wingless or with very short wing: cones green at maturity.
 C. Margin of lf. entire; lvs. $\frac{3}{4}$ -1½ in. long.
 D. Number of lvs. 3 or 4.
 E. Lvs. usually 4.....12. *Parryana*
 EE. Lvs. usually 3.....13. *cembroides*
 DD. Number of lvs. 1 or 2.
 E. Lvs. usually 2, sometimes 3. 14. *edulis*
 EE. Lvs. usually 1, sometimes 2. 15. *monophylla*
 CC. Margin of lf. serrulate: lvs. 3, 2-4 in. long.....16. *Bungeana*
 BB. Seeds with long wing: cones purple at maturity.
 C. Cones with minute incurved prickles.....17. *Balfouriana*
 CC. Cones with long slender prickles. 18. *aristata*

II. PITCH PINES (*Diploxyton*).

Wood usually heavy, coarse-grained, generally dark-colored, sap-wood pale, often thick: sheaths of lf.-clusters persistent (in the following species): lvs. with 2 fibro-vascular bundles, serrulate: umbo of cone-scales dorsal.

- A. Seed-wing very short or long and adnate.
 B. Wing very short, deciduous: lvs. 2, 5-8 in. long.....19. *Pinea*
 BB. Wing long, adnate: lvs. 3, 8-12 in. long.
 C. Apophysis broad-pyramidal; seed $\frac{1}{2}$ in. long.....20. *canariensis*
 CC. Apophysis elongated and more or less recurved; seed $\frac{3}{4}$ -1 in. long.....21. *longifolia*
 AA. Seed-wing articulate.
 B. Wing of seed membranous, long.
 C. Lvs. in 2's: cones deciduous, dehiscent at maturity, in No. 29 persistent and lvs. sometimes in 3's.
 D. Resin-ducts external.
 E. Branchlets bloomy: lvs. 2½-5 in. long.....22. *densiflora*
 EE. Branchlets not bloomy.
 F. Lvs. 4-8 in. long.
 G. Color of branchlets yellowish brown: lvs. dark green, slender and thin.....23. *Massoniana*
 GG. Color of branchlets orange: lvs. stout, light green.....24. *resinosa*
 FF. Lvs. $\frac{3}{4}$ -3 in. long.
 G. Umbo obtuse, gray: lvs. more or less bluish green.....25. *sylvestris*
 GG. Umbo more or less prickly, surrounded by a black marking: lvs. bright green....26. *montana*
 DD. Resin-ducts medial, or medial and external.
 E. Cones deciduous: resin-ducts medial.
 F. Winter buds brown, resinous, ovate-oblong.....27. *nigra*
 FF. Winter buds grayish white, cylindric.....28. *Thunbergii*
 EE. Cones tenaciously persistent: lvs. in 2's and 3's.....29. *sinensis*
 CC. Lvs. in 3's or in 2's and 3's.
 D. The cones deciduous.
 E. Resin-ducts medial.
 F. Young cones subterminal.
 G. Branchlets orange: cones 3-6 in. long...30. *ponderosa*
 GG. Branchlets glaucous: cones 5-15 in. long. 31. *Jeffreyi*

- FF. Young cones lateral.
 G. Lvs. 3-5 in. long.....32. *echinata*
 GG. Lvs. 6-9 in. long.....33. *Tæda*
 EE. Resin-ducts internal: lvs. 8-18 in. long.
 F. Winter buds whitish: cone dull brown, 6-10 in. long.....34. *palustris*
 FF. Winter buds light brown: cone lustrous, brown, 3-6½ in. long.....35. *caribæa*
 DD. The cones tenaciously persistent, often serotinous: resin-ducts medial (except in No. 36).
 E. Lvs. in 2's.
 F. Resin-ducts external: umbo obtuse.....36. *halepensis*
 FF. Resin-ducts medial.
 G. Cones symmetrical.
 H. Lvs. 6-8 in. long...37. *Pinaster*
 HH. Lvs. 1-3½ in. long.
 I. Prickles of cone stout.....38. *pungens*
 II. Prickles of cone slender.
 J. Cones remaining closed for many years...39. *clausa*
 JJ. Cones opening at maturity.....40. *virginiana*
 GG. Cones unsymmetrical.
 H. Length of lvs. less than 4 in.
 I. Cones not prickly, lateral.....41. *Banksiana*
 II. Cones prickly, subterminal.....42. *contorta*
 HH. Length of lvs. 4-6 in.: cones with stout and large prickles..43. *muricata*
 EE. Lvs. in 3's: cone prickly.
 F. Cones symmetrical.
 G. Length of lvs. 6-8 in.: cones remaining closed for 1 or 2 years.44. *serotina*
 GG. Length of lvs. 3-5 in.: cones opening at maturity.....45. *rigida*
 FF. Cones unsymmetrical.
 G. Prickles of cone minute: upper part of trunk rough.....46. *radiata*
 GG. Prickles of cone stout: upper part of trunk smooth.....47. *attenuata*
 BB. Wing of seed thick, short: lvs. 3 or 5, 6-13 in. long: cones large.
 C. Lvs. in 3's, 6-12 in. long.
 D. Cone conical-oblong; wings about 1 in. longer than the seed: lvs. stout.....48. *Coulteri*
 DD. Cones broadly ovate; wing about ½ in. longer than the seed: lvs. slender, flexible..49. *Sabiniana*
 CC. Lvs. in 5's, rigid, 8-13 in. long: cone broadly ovate; seed short-winged.....50. *Torreyana*

NO. 2. KEY FOR DETERMINING PINES WITHOUT CONES. (Compare Figs. 2958-2961.)

- A. Number of lvs. 5, only occasionally 3 or 4.
 B. Sheaths deciduous: fibro-vascular bundle 1.
 C. Edges of lvs. serrulate.
 D. Length of lvs. 1½-8 in.
 E. Branchlets glabrous or nearly so.
 F. The lvs. 6-8 in. long: branchlets glaucous... 7. *excelsa*
 FF. The lvs. 3-5 in. long: branchlets not glaucous.
 G. Tree a rather dense pyramid with ascending branches..... 6. *Peuce*

- GG. Tree an open pyramid.
 H. Lvs. bluish green. 8. *Strobus*
 HH. Lvs. bright green: habit loose, with wide-spreading branches. 3. *Armandi*
 EE. Branchlets densely brownish tomentose. 1. *Cembra*
 EEE. Branchlets pubescent or puberulous.
 F. Needles slender, somewhat pendulous, 4-6 in. long. 11. *Ayacahuite*
 FF. Needles stiff, $1\frac{1}{2}$ -4 in. long.
 G. Back of lvs. with fine white lines. 10. *Lambertiana*
 GG. Back of lvs. usually not lined.
 H. Color of lvs. bluish or dark green. 9. *monticola*
 HH. Color of lvs. bright green. 2. *koraiensis*
 DD. Length of lvs. $\frac{3}{4}$ - $1\frac{1}{2}$ in.: lvs. usually twisted, forming brush-like tufts at the end of the branchlets. 5. *parviflora*
 CC. Edges of lvs. entire.
 D. Lvs. $1\frac{1}{2}$ -3 in. long. 4. *flexilis*
 DD. Lvs. 1 - $1\frac{1}{2}$ in. long.
 E. Branchlets dark orange-brown: lvs. rigid. 17. *Balfouriana*
 EE. Branchlets orange: lvs. usually slender. 18. *aristata*
 BB. Sheaths persistent: fibro-vascular bundles 2: lvs. 8-12 in. long, rigid 50. *Torreyana*
 AA. Number of lvs. 3, or 4 or 1, only occasionally 2 or 5.
 B. Usually solitary, sometimes in 2's. 15. *monophylla*
 BB. Usually 4, sometimes 3 or 5. 12. *Parryana*
 BBB. Usually 3, occasionally 2.
 C. Fibro-vascular bundle 1: sheaths deciduous.
 D. Margin of lvs. entire: lvs. $\frac{3}{4}$ -2 in. long.
 E. Lvs. usually 3, 1-2 in. long. 13. *cembroides*
 EE. Lvs. usually 2, $\frac{3}{4}$ - $1\frac{1}{2}$ in. long. 14. *edulis*
 DD. Margin of lvs. serrulate: lvs. 2-4 in. long. 16. *Bungeana*
 CC. Fibro-vascular bundles 2: sheaths persistent.
 D. Branchlets glaucous: lvs. bluish or grayish green (see also No. 33.)
 E. Habit of lvs. slender, drooping. 49. *Sabiniana*
 EE. Habit of lvs. straight, stiff.
 F. Buds very resinous: lvs. 6-12 in. long, dark bluish green. 48. *Coulteri*
 FF. Buds not or little resinous: lvs. 5-8 in. long, pale bluish green. 31. *Jeffreyi*
 DD. Branchlets not glaucous: lvs. dark yellow or bright green.
 E. Habit of lvs. slender, drooping.
 F. Resin-ducts internal. 34. *palustris*
 FF. Resin-ducts external.
 G. Branchlets yellowish: buds brown. 20. *canariensis*
 GG. Branchlets light yellow-brown: buds bright chestnut-brown. 21. *longifolia*
 EE. Habit of lvs. stiff.
 F. Length of lvs. 6-12 in.
 G. Resin-ducts internal: buds cylindric, with spreading scales: lvs. dark green, in 2's and 3's, 8-12 in. long. 35. *caribæa*
 GG. Resin-ducts medial.
 H. Buds oblong-ovate, slightly or not resinous: lvs. 6-9 in. long.
 I. Lvs. light bluish green. 33. *Tæda*
 II. Lvs. dark yellow-green. 44. *serotina*
 HH. Buds ovate, acuminate, resinous: lvs. 5-11 in. long, dark yellowish green. 30. *ponderosa*
 FF. Length of lvs. 3-7 in. (see also No. 29).
 G. Character of lvs. slender.
 H. Foliage pale yellowish or bluish green: buds oblong-ovate, dark brown. 47. *attenuata*
 HH. Foliage bright green: buds ovate, bright chestnut-brown. 46. *radiata*
 GG. Character of lvs. stout.
 H. Form of buds thick, ovate, acute or acuminate. 30. *ponderosa* [var. *scopulorum*
 HH. Form of buds oblong-ovate. 45. *rigida*
 AAA. Number of lvs. 2 (see also No. 14).
 B. Branchlets glaucous.
 C. Buds very resinous. 40. *virginiana*
 CC. Buds not or little resinous.
 D. Hue of lvs. dark bluish green. 32. *echinata*
 DD. Hue of lvs. bright green. 22. *densiflora*
 BB. Branchlets not glaucous.
 C. Length of lvs. 1 - $3\frac{1}{2}$ in.
 D. Branchlets brown or orange: resin-ducts medial.
 E. Character of lvs. slender: branchlets brown. 39. *clausa*
 EE. Character of lvs. stout, twisted: branchlets orange or orange-brown.
 F. Lvs. 1 - $3\frac{1}{2}$ in. long.
 G. Resin-ducts 1 or 2. 42. *contorta*
 GG. Resin-ducts 2-5. 38. *pungens*
 FF. Lvs. $\frac{1}{2}$ -1 in. long. 41. *Banksiana*
 DD. Branchlets dull greenish yellow or greenish brown: resin-ducts external.
 E. Character of lvs. slender: buds not resinous. 36. *halepensis*
 EE. Character of lvs. stout: buds coated with resin.
 F. Generally a tree. 25. *sylvestris*
 FF. Generally a shrub. 26. *montana*
 CC. Length of lvs. 3-9 in.
 D. Color of buds whitish or grayish white. 28. *Thunbergii*
 DD. Color of buds brown (see also No. 36).
 E. Scales of the oblong buds with reflexed tips, chestnut-brown.
 F. Position of resin-ducts external.
 G. Habit of lvs. very slender and thin. 23. *Massoniana*
 GG. Habit of lvs. stiff and rigid. 19. *Pinea*
 FF. Position of resin-ducts medial or internal.
 G. Buds not resinous: lvs. lustrous green, 5-9 in. long. 37. *Pinaster*
 GG. Buds resinous: lvs. dark green, 4-6 in. long. 43. *muricata*
 EE. Scales not reflexed.
 F. Resin-ducts external: lvs. lustrous: buds ovate, acuminate, resinous. 24. *resinosa*
 FF. Resin-ducts medial: lvs. dull: buds ovate, acuminate, resinous. 27. *nigra*
 FFF. Resin-ducts medial and external: buds oblong-ovate, not resinous: lvs. sometimes 3. 29. *sinensis*

Section I. CEMBRA.

Group 1. CEMBRAE.

1. *Cembra*, Linn. SWISS STONE PINE. Tree, to 70 or sometimes 120 ft., with spreading usually short branches forming a narrow, dense pyramid, in old age often with very picturesque broad, open, round-topped head: branchlets coated with dense yellowish brown tomentum: winter buds globose-ovate, long-acuminate: lvs. straight, dark green on back, bluish white inside, 2-3½ in. long: cones short-peduncled, ovate, obtuse, light brown, 2½-3½ in. long; scales broadly ovate, rounded at apex, apophysis much broader than high; seed ½ in. long. Cent. European Alps. H.W. 1:8, pp. 174-7. G.W. 1, p. 352; 7, p. 19. G.C. II. 17:80, 81; III. 24:459. Gn. 19, p. 369; 28, pp. 175, 182; 59, p. 59; 65, p. 431. Gt. 45, p. 205; 58, p. 443.—Handsome hardy pine of slow growth and symmetrical habit when young. The large seeds are eaten. Var. *columnaris*, Beissn., is a form of narrow, columnar habit. G.W. 2, p. 209. Var. *compacta*, Beissn., is compact and conical in habit. Var. *sibirica*, Loud. (*P. sibirica*, Mayr), has shorter lvs. and longer cones, and is of narrower habit and more vigorous growth. N. Russia and Siberia. Var. *pumila*, Pall. See *P. pumila* in suppl. list.

2. *koraiensis*, Sieb. & Zucc. (*P. mandshurica*, Rupr.). Pyramidal tree, to 100 ft.: branchlets with yellowish brown pubescence: winter buds oblong-ovate, acuminate, dark chestnut-brown: lvs. straight, dark green and glossy on the back, bluish white on the inner sides, 2½-4 in. long: cones almost sessile, conic-oblong, yellowish brown, 4-6 in. long; scales rhombic-obovate, with recurved obtuse apex; seed over ½ in. long, brown, sharply edged. Japan, Korea. S.Z. 2:116. Gng. 6:1. F.E. 18:333; 25:35. S.I.F. 1:2.—In cult. of slow growth, forming a rather dense, broad pyramid, with handsome foliage. One of the best hardy pines for smaller gardens.

Group 2. FLEXILES.

3. *Armánde*, Franch. (*P. scipioniformis*, Mast. *P. Mastersiana*, Hayata). Tree, to 60 ft., with wide-spreading horizontal branches: branchlets glabrous: winter

2962. *Pinus flexilis* (×¼). No. 4.2963. *Pinus Strobus* (×¼). No. 8.

buds with a sharp edge all around. Cent. and W. China. B.M. 8347. G.C. III. 33:34 (as *P. koraiensis*), 66. R.H. 1910, p. 425.—A handsome pine which has proved hardy at the Arnold Arboretum.

4. *flexilis*, James. LIMBER PINE. Fig. 2962. Tree, to 50, occasionally to 80 ft., with stout horizontal branches forming a narrow open pyramid, in old age with low, broad, round-topped head: winter buds broadly ovate, slender-pointed: lvs. rigid, acute, dark green, 1½-3 in. long: cones short-stalked, ovate to cylindric-ovate, light brown, 3-6, rarely 10 in. long; scales rounded at the apex, tipped with an obtuse, dark umbo, the lower ones elongated and reflexed; seeds dark brown, mottled with black, ½-½ in. long, with narrow wing. Alberta to Calif. and New Mex. S.S. 11:546, 547. G.F. 10:165. B.M. 8467. M.D. 1904:49. F.E. 29:47.—Hardy pine of slow growth; seems to be best adapted for ornamental planting on rocky slopes. Var. *reflexa*, Engelm. (*P. reflexa*, Engelm. *P. strobiformis*, Sudw., not Engelm.). Tree, to 100 ft.: lvs. slender, to 4 in. long, entire or remotely serrulate: cones 5-9 in. long, on longer stalks, with often thin reflexed scales. Ariz. S.S. 11:544, 545. Var. *albo-variegata*, Schwerin. Has many of lvs. white.

Group 3. STROBI.

5. *parviflora*, Sieb. & Zucc. Tree, to 80 ft., of dense, pyramidal habit, with slender, horizontal branches: branchlets light greenish brown, puberulous: lvs. crowded, rather stiff, usually twisted, forming brush-like tufts at the end of the branchlets, bluish green, ¾-1½ in. long: cones ovate or oblong-ovate, almost sessile, reddish brown, 2-3 in. long; seeds dark brown, hardly ½ in. long, with short wing. Japan. S.Z. 2:115. S.I.F. 2:2. A.G. 14:212.—Hardy and very ornamental pine, bearing numerous decorative cones when older. Cult. plants are often grafted and assume a more irregular habit. In Japan it is often cult. in pots and dwarfed. Var. *glauca*, Beissn. With bluish green lvs. The wild form with somewhat longer lvs., longer cones and seeds with longer wings has been described as *P. pentaphylla*, Mayr.

6. *Peuce*, Griseb. (*P. excelsa* var. *Peuce*, Beissn.). Attains 50 ft., with ascending short branches forming a narrow dense pyramid: branchlets greenish, glabrous, not glaucous: winter buds ovate: lvs. straight, bluish green, 3-4 in. long: cones short-stalked, cylindric, 3½-6 in. long, with obovate scales; seed 4 lines long. S.E. Eu. Gn. 76, p. 613.—An ornamental hardy pine of

dense, regular habit and slow growth; forms a narrower and denser pyramid than the white pine (*P. Strobus*).

7. *excelsa*, Wall. (*P. nepalensis*, Chambr.). Attains 150 ft., with spreading and slightly ascending branches forming a broad open pyramid; branchlets greenish, glabrous, glaucous: winter buds cylindric-obovate, acute: lvs. slender, flaccid, drooping, grayish or bluish green, 6-8 in. long; cones cylindric on 1-2-in.-long stalks, 6-10 in. long; seeds brown, 4 lines long. Himalayas. Gn. 31, p. 195. A.G. 19:149. F.E. 13:664 (pl. 8); 33:113. Gn.M. 6:290. M.D.G. 1903:185.—Handsome tree, of somewhat loose habit, with graceful pendulous foliage, hardy as far north as Mass. in sheltered positions.

Var. *zebrina*, Bailly (var. *variegata*, Hort.), has the lvs. with a whitish zone near the tip. F.E. 31:191. R.H. 1889, p. 392.

8. *Ströbus*, Linn. (*Ströbus Ströbus*, Small). WHITE PINE. Figs. 2958, 2963, 2964. Attains 100, occasionally 150 ft., with horizontal branches in regular whorls forming a symmetrical open pyramid; in old age the head is usually broad and open and often very picturesque: branchlets greenish or light greenish brown, glabrous or slightly puberulous: winter

buds ovate, acuminate: lvs. soft, bluish green, 2-4 in. long (or $3\frac{1}{2}$ -5): cones on stalks $\frac{1}{2}$ -1 in. long, cylindric, slender, often curved, 2-4 in. long, with oblong-obovate scales; seed red-brown, mottled with black, 3 lines long. Newfoundland to Man., south to Ga., Ill. and Iowa. S.S. 11:538, 539. A.G. 12:645; 13:1. Gn. 30, p. 404. F.E. 15:340. C.L.A. 11:310. H. W. 1:9, pp. 183-5.—Very valuable ornamental hardy pine of rapid growth, symmetrical when young, picturesque in old age: no tree is better adapted to break up the monotonous sky-line of plantations in northern parks. There are a number of gardens forms occasionally cult. Var. *álba*, Loud. (var. *nívea*, Carr.). Low form of irregular habit, with almost silvery white foliage. Var. *aúrea*, Carr. With yellow foliage. Var. *gláuca*, Beissn. With light bluish green foliage. Var. *brevifolia*, Loud. (var. *nana*, Knight. Var. *pygmæa*, Hort.). Dwarf, compact, round bush, with short lvs. F.E. 20:788 (pl. 112); 29:569. Gt. 52, p. 435. Gn. M. 2:23. Var. *fastigiata*, Beissn. (var. *pyramidalis*, Hort.). With ascending branches, of narrow pyramidal or columnar habit. Var. *prostrata*, Arb. Kew. Dwarf, procumbent form, diffuse and trailing on the ground. Var. *umbraculifera*, Knight. Dwarf, flat-topped bush, with short lvs. R.H. 1869, p. 38. There are also forms with variegated foliage.

2964. *Pinus Strobus*. ($\times \frac{1}{2}$)

9. *monticola*, Don. MOUNTAIN WHITE PINE. Tree, to 100 or occasionally 150 ft., with slender, spreading, somewhat pendulous branches forming a narrow open pyramid: branchlets puberulous, yellowish or reddish brown: winter buds ovate, acute: lvs. stiff, bluish green and glaucous, $1\frac{1}{2}$ -4 in. long, with few inconspicuous or no lines on the back: cones short-peduncled, cylindric, slender, slightly curved, 5-11 in. long, yellowish brown: scales pointed by the slightly thickened umbo; seed red-brown, mottled with black, $\frac{1}{2}$ in. long. Brit. Col. to Idaho and Calif. S.S. 11:540, 541. G.F. 5:5, 7. R.H. 1869, p. 126 (as *P. Groezelieri*). F.E. 31:293.—Similar to *P. Strobus*, but forming a somewhat narrower, more slender pyramid; hardy as far north as Mass.

10. *Lambertiana*, Douglas. SUGAR PINE. Fig. 2965. Tree, to 200 or 220 ft., with spreading somewhat pendulous branches forming a narrow open pyramid; old trees usually with flat-topped wide-spreading open head: branchlets brown, pubescent: winter buds oblong-obovate, apiculate: lvs. stout, sharply pointed, dark bluish green, 3-4 in. long, with conspicuous white lines on the back: cones on peduncles 2- $3\frac{1}{2}$ in. long, cylindric, often slightly curved, light brown, lustrous, 10-20 in. long; seed about $\frac{1}{2}$ in. long, dark brown or nearly black. Ore. to Mex. S.S. 11:542, 543. Gn. 31, pp. 152, 153. G.C. II. 23:11; III. 1:769. F.S.R. 1, p. 129. M.D.G. 1905:126. G.W. 8, p. 617.—One of the tallest trees of the Pacific Coast; in the eastern states it is hardy as far north as Mass., but grows slowly; has handsome dark foliage.

11. *Ayacahuite*, Ehrenb. (*P. Bonaparteae*, Roehl. *P. Don-Pedrii*, Roehl. *P. Loudoniana*, Gord.). Tree, to 100 ft., with spreading, slender branches: branchlets yellowish brown, finely pubescent: lvs. slender and somewhat pendulous, bluish green, 4-6 in. long: cones short-stalked, cylindric-conical, gradually narrowed toward the apex, often slightly curved, brownish yellow, 9-15 in. long; seeds about $\frac{1}{2}$ in. long, gray-brown, mottled dark brown. N. Mex. G.C. II. 18:493; III. 20:751, 753. Gn. 25, pp. 192, 193. C.L.A. 7:364.—Handsome tree, somewhat resembling the white pine, but foliage more slender, especially ornamental with its large cones. Not hardy N.

Section II. PARACEMBRA.

Group 4. CEMBROIDES.

12. *Parryana*, Engelm., not Gord. (*P. quadrifolia*, Sudw.). NUT PINE. PINNON. Tree, to 40 ft., with stout, spreading branches, forming a regular pyramid, but in old age usually round-topped and irregular: branchlets puberulous, light grayish brown: lvs. 3-5, usually 4, rigid, incurved, pale glaucous green, $1\frac{1}{2}$ - $1\frac{3}{4}$ in. long: cone subglobose, $1\frac{1}{2}$ -2 in. broad, chestnut-brown, lustrous; apophysis thick, pyramidal, conspicuously keeled; umbo with minute recurved prickles; seed about $\frac{1}{2}$ in. long. Calif. S.S. 11:549. M.D.G. 1903:97.—Not hardy N.

2965. Cones of pines. Beginning at the top: *P. Coulteri*, *P. Lambertiana*, *P. parvistris*, *P. radiata*. ($\times \frac{1}{2}$)

13. *cembroides*, Zucc. (*P. osteosperma*, Engelm.). Small tree, usually not over 20 ft., with stout spreading branches forming a round-topped head: branchlets dark orange, pubescent at first: lvs. usually 3, sometimes 2, slender, dark green, with stomata on all 3 faces, much incurved, 1-2 in. long: cone subglobose, 1-2 in. broad; apophysis pyramidal, strongly keeled, lustrous brown, with broad obtuse umbo; seeds oblong-obovate, $\frac{1}{2}$ - $\frac{3}{4}$ in. long, dark brown, with very narrow wing. Ariz. to Low. Calif. and N. Mex. S.S. 11:550. G.F. 4:353. F.S. 4, p. 325b.—A slow-growing densely branched pine; tender. By some authors the preceding and the two following species are referred to this species as simple variations in the number of lvs.

14. *edulis*, Engelm. (*Caryopitys edulis*, Small). NUT PINE. Fig. 2966. Small tree, 10-20 or occasionally to 40 ft., with horizontal branches, bushy when young, with low, round-topped head in old age: branchlets light yellowish brown, puberulous at first: lvs. 2-3, rigid, dark green, $\frac{3}{4}$ -1 $\frac{1}{2}$ in. long: cones almost sessile, broadly ovate, greenish yellow, lustrous, about 1 $\frac{1}{2}$ in. long; apophysis pyramidal, strongly keeled; umbo with minute recurved tip; seed $\frac{1}{2}$ in. long, with narrow wing remaining attached to the scale. Colo. to N. Mex. and Texas. S.S. 11:552. F.E. 29:205.—Hardy as far north as Mass., forming a slow-growing and compact bush. The seeds are an important article of food among the Indians. Var. *álbo-variegata*, Hort., has white lvs. mixed with the green ones.

15. *monophylla*, Torr. & Frem. (*P. Fremontiana*, Endl.). Tree, 15-20, occasionally to 50 ft., similar to the preceding: branchlets light orange, glabrous: lvs. usually solitary, sometimes 2, terete, rigid, spinescent, glaucous green, $\frac{3}{4}$ -1 $\frac{1}{2}$ in. long: cones broadly ovate, light brown, 1 $\frac{1}{2}$ -2 in. long; apophysis depressed-pyramidal, ridged, the flattened umbo with a minute incurved tip; seed $\frac{1}{2}$ in. long. Calif. to Colo. and Ariz. S.S. 11:551. G.C. II. 20:44; 26:137.—Of slow growth, hardy as far north as Mass. The solitary lf. has been believed to consist of 2 connate ones, but this is certainly not the case, as the solitary fibro-vascular bundle plainly shows.

2966. *Pinus edulis*.
($\times \frac{1}{4}$)

Group 5. GERARDIANÆ.

16. *Bungeana*, Zucc. LACE-BARK PINE. WHITE-BARK PINE. Tree, to 80 or 100 ft., with long and slender branches: bark flaky, light gray: young branches grayish green, glabrous: lvs. rigid, acute, light green, 2-4 in. long: cones almost sessile, conic-ovate, light yellowish brown, 2-3 in. long; apophysis much broader than high, ridged, with a triangular pointed and recurved umbo; seed dark brown, with narrow wing, $\frac{1}{4}$ - $\frac{1}{2}$ in. long. N. W. China. B.M. 8240. G.C. II.

18:9.—Hardy slow-growing tree of bushy habit in cult. and with rather sparse light green foliage.

Group 6. BALFOURIANÆ.

17. *Balfouriana*, Jeffrey. FOXTAIL PINE. Tree, to 40, occasionally 90 ft., narrow-pyramidal when young, irregular and open in old age: branchlets dark brown,

2967. Scotch pine.—*Pinus sylvestris* ($\times \frac{1}{4}$). No. 25.

puberulous at first: lvs. crowded, incurved and pressed against the branches, rigid, acute, dark green on the back, with conspicuous white lines inside, 1-1 $\frac{1}{2}$ in. long, remaining for 10-12 years on the branches: cones pendulous, subcylindric, dark purplish brown, 3 $\frac{1}{2}$ -5 in. long; apophysis flattened, the concave oblong umbo with minute incurved prickles; seed $\frac{1}{2}$ in. long. Calif. S.S. 11:553.—Not hardy N.

18. *aristata*, Engelm. (*P. Balfouriana* var. *aristata*, Engelm.). HICKORY PINE. FOXTAIL PINE. Bushy tree, occasionally to 50 ft., sometimes a semi-prostrate shrub: branchlets light orange and almost glabrous: lvs. stout or slender, dark green, 1-1 $\frac{1}{2}$ in. long, with white lines inside: cones cylindric-ovate, 3-3 $\frac{1}{2}$ in. long; apophysis elevated; umbo with a slender incurved spine to $\frac{1}{4}$ in. long; seed $\frac{1}{4}$ in. long. Calif. to Utah and Ariz. S.S. 11:554. G.C. III. 20:719. M.D. 1904, p. 49 (pl. 5).—Hardy as far north as Mass.; in cult. usually a handsome low, bushy shrub of distinct habit: lvs. often sprinkled with resinous dots.

Section III. PARAPINASTER.

Group 7. PINÆ.

19. *Pinea*, Linn. STONE PINE. Tree, to 80 ft., with long, horizontally spreading branches forming in older trees a broad, flat-topped head: branchlets pale brown: buds with revolute scales, oblong-ovate, not resinous: lvs. rigid, acute, bright green, 5-8 in. long: cones broadly ovate, chestnut-brown, 4-5 $\frac{1}{2}$ in. long; apophysis depressed-pyramidal, radiately ridged; umbo flat, obtuse; seed reddish brown, $\frac{3}{4}$ in. long, edible. S. Eu. G.C. II. 20:45; III. 4:604, 605. Gn. 27, pp. 245-7; 50, p. 460; 76, p. 648. H.W. 1, pp. 170, 171. F.S.R. 2, p. 274. J.H. III. 68:447.—Tree of picturesque habit, with a trunk usually destitute of branches for a considerable height and with a wide-spreading parasol-like head. Not hardy N.; in warmer regions often cult. for its edible seeds.

Group 8. LONGIFOLIÆ.

20. *canariensis*, C. Smith. Tree, to 80 ft., with slender branches forming a broad, round-topped head: branchlets yellowish: lvs. slender, spreading and pendulous, light green and lustrous, 9-12 in. long, with medial resin-ducts: cones cylindric-ovate, 4-8 in. long; apophysis low-pyramidal, irregularly 4-sided, light brown and

glossy, with obtuse umbo; seed $\frac{1}{2}$ in. long. Canary Is. G.C. III. 3:721.—Handsome pine cult. in Calif., where it does very well and grows faster than the native *P. radiata*, even in very rocky and dry locations; in colder regions grown sometimes in the greenhouse.

21. *longifolia*, Roxbg. (*P. Roxburghii*, Sarg.). Tree, to 100 ft. or more, with round-topped symmetrical

2968. Mugho pine.—*Pinus montana* var. *Mugho*. No. 26.

head: branchlets light yellow-brown: winter buds oblong, light chestnut-brown, not resinous: lvs. slender, pendulous, light green, 8–12 in. long, with external resin-ducts: cones short-stalked, conic-ovate, 4–7 in. long; apophysis elongated-pyramidal, compressed, more or less recurved; umbo obtuse; seed $\frac{3}{4}$ –1 in. long. Himalayas.—Important forest tree in its native country. Not hardy N., but cult. in Calif. Very decorative as a young plant, with its long drooping light green foliage.

Section IV. PINASTER.

Group 9. LARICIONES.

22. *densiflora*, Sieb. & Zucc. JAPANESE RED PINE. Tree, to 100 ft., with spreading branches forming an irregular, rather broad head: branchlets orange-yellow, bloomy: buds oblong-ovate, chestnut-brown: lvs. slender, acute, bright bluish green, $2\frac{1}{2}$ –5 in. long: cones short-stalked, conic-ovate to oblong, grayish brown, somewhat oblique at the base, about 2 in. long; apophysis flattened and slightly ridged, those near the base sometimes elongated; umbo small, with a short prickly or obtuse; seed grayish yellow, $\frac{1}{4}$ in. long. Japan. S.Z. 2:112. S.I.F. 1:1. Gn.M. 2:22.—Ornamental hardy tree, rapidly growing when young, often very picturesque when older. Many garden forms are cult. in Japan, several of them with variegated lvs. The best are perhaps var. *umbraculifera*, Mayr, a low form with horizontally spreading branches forming a flat head; var. *péndula*, Mayr, with pendulous branches; var. *aurea*, Mayr, with yellow foliage; var. *álbo-terminata*, Mayr, with the tips of the lvs. yellowish white, and var. *Oculus-draconis*, Mayr, like var. *variegata*, Mayr, similar to the varieties, of the same name under *P. Thunbergii*. (No. 28.)

23. *Massoniàna*, Lamb. Tree, to 80 ft., with slender, spreading branches: branchlets yellowish brown: lvs. very slender and thin, light green, 5–8 in. long: cones oblong-ovate or ovate, dull brown, 2–3 in. long; apophysis flattened, slightly keeled, with a small, flat, unarmed umbo; seed $\frac{1}{2}$ in. long. China.—Not hardy N. and rarely cult. Often confounded with *P. sinensis* and *P. densiflora*.

24. *resinosa*, Ait. RED PINE. NORWAY PINE. Tree, to 70, occasionally to 150 ft., with stout spreading and sometimes pendulous branches forming a broad pyramidal head when young and an open round-topped one in old age: branchlets orange-color: buds ovate, acuminate, light brown, resinous: lvs. slender and flexible, acute, dark green and lustrous, 4–6 in. long: cones subsessile, conic-ovate, light brown, $1\frac{1}{2}$ –2 $\frac{1}{2}$ in. long; apophysis flattened, conspicuously keeled, obtuse, with small dark unarmed umbo; seeds dark brown, $\frac{1}{8}$ in.

long. Newfoundland to Man., south to Pa. and Minn. S.S. 11:550, 551. A.G. 12:645. C.L.A. 11:310.—One of the most ornamental pines for northern parks, quite hardy and of vigorous growth. Lumber tree.

25. *sylvéstris*, Linn. SCOTCH or SCOTS PINE. Fig. 2967. Tree, to 70, or occasionally 120 ft., with spreading, often somewhat pendulous branches, pyramidal when young, with broad and round-topped often picturesque head in old age: branchlets dull grayish yellow: winter-buds oblong ovate, brown, resinous: lvs. rigid, acute, twisted, bluish green, $1\frac{1}{2}$ –3 in. long: cones short-stalked, conic-oblong, grayish or reddish brown, $1\frac{1}{2}$ –2 $\frac{1}{2}$ in. long; apophysis little thickened, slightly keeled, only those near the base elongated; umbo small, obtuse; seed dark gray, $\frac{1}{6}$ in. long. Eu. to W. and N. Asia. Gn. 36, p. 167; 38, p. 455; 49, p. 296. H.W. 1:4, pp. 121–6. F.E. 29:157. G.C. III. 34:298. F.S.R. 1, p. 16.—One of the most important timber trees of Eu. It is quite hardy, but has little to recommend it as an ornamental tree. Several geographical and garden forms have been distinguished. Var. *argétea*, Stev. Foliage light bluish green, with silvery hue. Var. *aúrea*, Beissn., with the young lvs. golden yellow. F.E. 13:972 (pl. 14). Var. *nívea*, Schwerin. Lvs. a dirty greenish white. Var. *Beissneriàna*, Schwerin. Lvs. green at first, changing to golden yellow in summer. Var. *columnaris compácta*, Bailly. Slow-growing, dense, columnar form. R.H. 1889, p. 393. Var. *fastigiata*, Carr. (var. *pyramidàlis*, Hort.). Of pyramidal habit. Var. *virgata*, Casp. Sparingly branched form with long flagellate branches. H.W. 1, p. 126. Var. *crispata*, Schwerin. Lvs. curved in different directions, having a crisp appearance. Var. *péndula*, Beissn. With pendulous branches. Var. *pùmila*, Beissn. Dwarf globose bush. Besides these varieties a number of geographical races have been distinguished which differ chiefly in habit, growth, and hardiness and are more of silvicultural than of horticultural interest. The best known are var. *rigénsis*,

2969. Austrian pine.—*Pinus nigra* var. *austriaca* ($\times \frac{1}{2}$). No. 27.

Loud., with a straight tall st.; var. *lappónica*, Fries (*P. lappónica*, Mayr). A pyramidal form of slow growth: lvs. broader and shorter, remaining green on the branches for 4–7 years: cones more yellowish. N. Eu. Var. *engadinénsis*, Heer. A slow-growing pyramidal form with thick and rigid lvs. $1\frac{1}{2}$ in. long and grayish green. Tyrol.

26. *montana*, Mill. SWISS MOUNTAIN PINE. Very variable in habit, usually low, often prostrate shrub, sometimes pyramidal tree to 40 ft., similar to the preceding: branchlets usually of darker, brownish color: lvs. bright green, acutish, stout, crowded, $\frac{3}{4}$ -2 in. long: cones ovate or conic-ovate, $\frac{3}{4}$ -2 $\frac{1}{4}$ in. long; apophysis often pyramidal; umbo light gray, surrounded by a blackish ring. An anatomical character in the lvs. to distinguish this species from the preceding is found in the cells of the epidermis which are of nearly equal diam. with a dot-like central space in *P. sylvestris*, but in this species are much higher than broad with a dash-like central space.

2970. *Pinus ponderosa*. ($\times \frac{1}{2}$)

Mts. of Cent. Eu. Gn. 30, p. 225. Mn. 5, p. 49. H.W. 1:5, pp. 140-3. M.D. 1912, pp. 141-8. G.W. 1, p. 351.—Handsome hardy low shrub with ascending branches densely clothed with bright green foliage; ornamental as single specimens or for covering rocky slopes and as undergrowth in open woods. A very variable species which has been divided according to the cones into the following 3 varieties or subspecies: Var. *uncinata*, Willk. (including vars. *rostrata* and *rotundata*, Ant., var. *arborea*, Tubeuf). Cone very oblique, usually deflexed; apophysis pyramidal, with often reflexed umbo. Often arborescent. Var. *pumilio*, Willk. (*P. pumilio*, Haenke. *P. carpatica*, Hort., var. *frutescens erecta*, Tubeuf). Cone regular, subglobose to ovate, before maturity glaucous and usually violet-purple, ripe yellowish or dark brown. Usually shrubby and upright. Var. *Mughus*, Willk. (*P. Mughus*, Scop., var. *prostrata*, Tubeuf). Fig. 2968. Cone regular, conical or conic-oval, with usually prickly umbos, not bloomy, yellowish brown before ripening, cinnamon-brown when ripe. Usually shrubby and prostrate. Gn. M. 2:23. Var. *aureo-variegata*, Schwerin, has some of lvs. golden yellow. Var. *gracilis*, Schwerin, is a regular pyramidal form with lvs. 1-1 $\frac{1}{4}$ in. long. M.D. 1906, p. 193.

27. *nigra*, Arnold (*P. Laricio*, Poir.). AUSTRIAN PINE. Tree, to 100 or occasionally 150 ft., with stout, spreading branches in regular whorls forming a symmetrical pyramid, in old age sometimes broad and flat-topped: branchlets usually light brown: buds ovate or oblong-ovate, light brown, resinous: lvs. stiff, acute, dark green, 3-6 $\frac{1}{2}$ in. long: cones sessile, ovate, yellowish brown, glossy, usually 2-3 $\frac{1}{2}$ in. long; apophysis depressed, conspicuously keeled; umbo flattened, obtuse or with a very short prickle; seeds gray, $\frac{1}{4}$ in. long. S. Eu. to W. Asia.—Very variable and usually the following geographical varieties are distinguished: Var. *austriaca*, Schneid. (*P. Laricio* var. *austriaca*, Endl. *P. austriaca*, Höss. *P. nigricans*, Hort.). Fig. 2969. Tall tree, with dark gray bark, broadly ovate head and very dark green, rigid lvs. 3-4 in. long: branchlets grayish or yellowish brown. S.E. Eu., from Austria to Dalmatia and Rumania. Gn. 19,

2971. *Pinus taeda* ($\times \frac{1}{2}$). No. 33.

p. 477; 38, p. 113. F.S.R. 3, p. 10. F.E. 18:376 (pl. 84). G.W. 15, p. 466, H.W. 1:6, pp. 148-51. Mn. 10, p. 170. R.H. 1894, p. 271. Var. *Pallasiana*, Schneid. (*P. Pallasiana*, Lamb.). CRIMEAN PINE. Tall tree, with long and stout branches: lvs. dark green and glossy: cones light brown, about 4 in. long. W. Asia. G.C. II. 20:785; 21:481. Var. *calabrica*, Schneid. (*P. Laricio calabrica*, Delam.). CALABRIAN PINE. Tall tree, with shorter ascending branches forming a narrower, less dense head: lvs. of lighter green: branchlets light brown. Italy, Sicily. Var. *pindica*, Rehd. (*P. Laricio pindica*, Mast. *P. pindica*, Formanek). Lvs. pale green, about 5 in. long: cones about 3 in. long with convex apophysis and small obtuse umbo. Thessaly. G.C. III. 31:304. Var. *leucodermis*, Rehd. (*P. leucodermis*, Ant.). Pyramidal tree: bark light gray, broken into angular plates: lvs. dark green, 2-4 in. long: cones oblong-ovate, light grayish brown, dull, about 3 in. long. S. E. Eu. H.W. 1, p. 158-61. Var. *Poiretiana*, Schneid. (*P. Laricio*, Poir. *P. Laricio corsicana*, Hort.). CORSICAN PINE. Tall tree, to

2972. Seedlings and young plant of *Pinus palustris*. No. 34.

150 ft., with shorter ascending branches forming a narrower head: bark gray: branchlets reddish brown: lvs. lighter green, 4-6 in. long. Corsica. R.H. 1897, pp. 355, 357. F.S.R. 1, p. 33. Gn. 27, p. 321; 29, p. 104; 36, p. 523; 52, p. 219. G.C. II. 21:15; III. 4:693, 705. Var. *tenuifolia*, Schneid. (*P. Laricio tenuifolia*, Parl. *P. Salzmannii*, Dun. *P. monspeliensis*, Salzmann. *P. pyrenaica*, Lapeyr. *P. cebennensis*, Hort. *P. horizontalis*, Hort.). Tree, to 60 ft.: branchlets orange-colored: lvs. slender, to 6 $\frac{1}{2}$ in. long: cones small, about 2 in. long. Of the horticultural varieties may be mentioned var. *péndula*, Rehd. (*P. Laricio péndula*, Beissn.); var. *pygmæa*, Rehd. (*P. Laricio pygmæa*, Rauch), a dwarf dense bushy form; var. *prostrata*, Rehd. (*P. L. prostrata*, Beissn.), of prostrate habit, and var. *Möseri*, Rehd. (*P. L. Möseri*, Moser), compact and dwarf, needles turning golden yellow in winter.—The var. *austriaca* is hardy N., the others are at least hardy as far north as Mass. They are of rapid growth and conspicuous by their large, dark green foliage. Var. *tenuifolia*

is especially very handsome as a young plant, with its long, dense lvs.

28. *Thunbergii*, Parl. (*P. Massoniana*, Sieb. & Zucc., not Lamb.). JAPANESE BLACK PINE. Tree, to 100 ft., or occasionally 120 ft., with spreading, often somewhat pendulous branches, forming a broad, pyramidal head:

2973. Cone of *Pinus palustris* ($\times \frac{1}{2}$). No. 34.

branchlets orange-yellow, the winter buds oblong, grayish or silvery white; lvs. stiff, sharply pointed, bright green, 3-4½ in. long; cones short-stalked, conic-ovate, grayish brown, 2-3 in. long; apophysis flattened, with small, depressed umbo, obtuse or with a minute prickle; seed grayish brown, ¼ in. long. Japan. G.C. II. 23:345. S.Z. 2:113. S.I.F. 1:1.—Handsome tree and hardy N. Several horticultural varieties have been intro. from Japan: one of the most distinct is var. *Oculus-draconis*, Mayr, each lf. being marked with 2 yellow bands and therefore the tufts of the lvs. at the end of the branches, if seen from above, show alternate yellow and green rings, hence the name *Oculus-draconis* (dragon-eye). Var. *variegata*, Hort., has the lvs. partly

yellow or occasionally wholly yellowish white. There are also similar forms in *P. densiflora*, which may be distinguished by the brown color of the winter buds.

29. *sinensis*, Lamb. (*P. leucosperma*, Maxim. *P. funebris*, Komar. *P. Henryi*, Mast. *P. Wilsonii*, Shaw. *P. tabuliformis*, Carr.). Tree, to 70 ft.: bark of trunk dark gray, fissured, red on the limbs: branchlets pale orange-yellow or pale grayish yellow, slightly bloomy while young; winter buds oblong, light brown, lustrous, slightly or not resinous; lvs. 2-3, oftener 2, stiff, glaucous, with rough margins, 2-4 in. long; cones subsessile, ovoid, 1½-2½ in. long, persistent for several years, pale yellow-brown; apophysis rhombic, prominently keeled, with an obtuse or mucronate umbo; seeds brown, mottled or whitish, over ¼ in. long, with the wing ¾ in. long. Cent. and W. China. Var. *densata*, Shaw (*P. densata*, Mast. *P. prominens*, Mast.). Lvs. 3-5 in. long, stiff: cones ovoid, 2-2½ in. long, oblique, with their posterior apophysis tumid and prominent. Var. *yunnanensis*, Shaw (*P. yunnanensis*, Franch.). Lvs. oftener 3, slender, 4-8 in. long; cones 2½-3½ in. long; apophysis flat; umbo small; seed with wing nearly 1 in. long. S.W. China. G.C. III. 38:226.

2974. Leaf-bundle of *Pinus palustris*. No. 34.

Group 10. AUSTRALES.

30. *ponderosa*, Douglas (*P. Benthamiana*, Hartw.). YELLOW PINE. BULL PINE. Fig. 2970. Tree, to 150, occasionally to 230 ft., with stout spreading and often pendulous branches usually ascending at the ends and forming a narrow, spire-like head: branchlets orange-brown, fragrant when broken: winter buds oblong-ovate or ovate, resinous; lvs. acute, dark green, 5-11 in. long; cones almost sessile, often in clusters, ovate-oblong, light reddish or yellowish brown and lustrous, 3-6 in. long; apophysis depressed-pyramidal or flattened, with a broadly triangular umbo terminated by a stout, usually recurved prickle; lower scales with more elongated apex; seed ¼ in. long. Brit. Col. to Mex., east to Neb. and Texas. S.S. 11:560, 561. G.F. 8:395. G.C. III. 8:557, 561, 569. F.S.R. 3, p. 99. M.D.G. 1905:126.—One of the tallest and most important pines of the western states. Hardy as far north as N. Y., and in sheltered positions to Mass. Var. *pendula*, H. W. Sarg., has drooping branches. Var. *scopulorum*, Engelm. (*P. scopulorum*, Lemm.), is a geographical variety, smaller in every part; usually to 75 ft. high; lvs. 5-7 in. long, sometimes in 2's: cones smaller, ovate. S. D. to Mex. and Texas. S.S. 11:564. G.C. II. 9:797. M.D. 1912, p. 364. Somewhat harder than the type.—*P. Malletii*, Mott., is probably a form of this species with more ascending branches forming a rather narrow pyramidal head. R.H. 1913, p. 265. Fig. 2970 is adapted from Pacific R. R. Report.

31. *Jeffreyi*, Balfour (*P. ponderosa* var. *Jeffreyi*, Vasey). JEFFREY'S PINE. Tree, to 120 or occasionally to 180 ft., with short spreading or often pendulous branches, the uppermost ascending, forming an open pyramidal and sometimes narrow spire-like head: young branches glaucous, fragrant when broken: winter buds oblong-ovate, not resinous; lvs. stout, acute, pale bluish green, 5-8 in. long; cones conic-ovate, light brown, 6-12 in. long; apophysis depressed, keeled; umbo elongated into a slender recurved spine; seed about ½ in. long. Ore. to Calif. S.S. 11:562, 563. G.C. II. 22:813; III. 5:361, 369. G.F. 5:185. B.M. 8257. G.W. 2, p. 199.—Distinct and ornamental pine of symmetrical habit when young, hardy as far north as Mass. Among the harder species this pine has the longest lvs.

32. *echinata*, Mill. (*P. mitis*, Michx.). SPRUCE PINE. YELLOW PINE. Tree, to 100 or 120 ft., with slender often pendulous branches in regular whorls: winter buds oblong-ovate, brown; lvs. slender, acute, dark bluish green, sometimes in 3's, 3-5 in. long; cones short-stalked or almost sessile, conic-oblong, dull brown, 1½-2 in. long; apophysis flattened; umbo little elevated, with short straight or curved prickle;

2975. *Pinus caribaea* ($\times \frac{1}{2}$). No. 35.

2976. *Pinus caribaea*. ($\times \frac{2}{3}$)

seeds $\frac{1}{2}$ – $\frac{1}{4}$ in. long. N. Y. to Fla., west to Ill. and Texas. S.S. 11:587.—Handsome tree, with broad, oval head, hardy as far north as Mass.

33. *Tæda*, Linn. LOBLOLLY PINE. OLD FIELD PINE. FRANKINCENSE PINE. Fig. 2971 (adapted from U. S. Forestry Report). Tree, to 100, occasionally to 170 ft., with spreading branches, the upper ascending, forming a compact round-topped head: branchlets yellowish brown, sometimes slightly bloomy: winter buds oblong, resinous: lvs. slender but stiff, acute, bright green, 6–9 in. long: cones sessile, spreading, conic-oblong, light reddish brown, 3–5 in. long; apophysis flattened or depressed-pyramidal; umbo small, with short triangular, recurved spine, lower scales not elongated; seed $\frac{1}{2}$ in. long. Del. to Fla. and Texas. S.S. 11:577, 578.—Not hardy N., and rarely cult. for ornament.

34. *palustris*, Mill. (*P. australis*, Michx.). LONG-LEAF PINE. SOUTHERN PINE. Figs. 2965, 2972–2974. Tree, to 100 or 120 ft., with ascending branches forming an oblong open head: branchlets orange-brown: winter buds whitish, oblong; lvs. crowded, forming tufts at the end of branchlets, dark green, 8–18 in. long, with internal resin-ducts: cones almost sessile, cylindric, dull brown, 6–10 in. long; apophysis flattened; umbo dark brown, with triangular, reflexed short spines; seed almost $\frac{1}{2}$ in. long. Va. and Fla., to Miss., along the coast. S.S. 11:589, 590. G.F. 10:115.—Very important timber tree, but rarely planted for ornament; hardy only S.

2977. Cone of *Pinus clausa* (natural size). No. 39.

Branches are imported in great quantities into the northern cities in midwinter and used for decorations on account of their large handsome foliage. Figs. 2972–2974 are adapted from U. S. Forestry Report.

35. *caribæa*, Morelet (*P. cubensis*, Griseb. *P. heterophylla*, Sudw. *P. Elliottii*, Engelm.). SLASH PINE. SWAMP PINE. Figs. 2975, 2976. Tree, to 100 or 120 ft., with horizontally spreading branches forming a round-topped broad and compact head: branchlets orange-brown: winter buds cylindric, light brown: lvs. dark green and lustrous, acute, in 3's and 2's, 8–12 in. long, with internal resin-ducts: cones short-peduncled, conic-oblong, dark brown and glossy, 3–6 $\frac{1}{2}$ in. long; apophysis flattened, keeled; umbo small, with minute recurved prickles; seed $\frac{1}{6}$ – $\frac{1}{4}$ in. long. Ga. to Fla., near the coast, Cuba. S.S. 11:591, 592. G.C. III. 35:179. G.F. 8:223 (adapted in Fig. 2996).—Handsome pine, with compact broad head, hardy only S. Fig. 2975 is adapted from U. S. Forestry Report.

Group 11. INSIGNES.

36. *halepensis*, Mill. (*P. alepensis*, Poir.). ALEPPIC PINE. Tree, to 60 ft., with short branches forming an open round-topped head: branchlets slender, yellowish or light greenish brown: winter buds small, cylindric, not resinous: lvs. sometimes in 3's, slender, light green, 2 $\frac{1}{2}$ –4 in. long: cones short-stalked, spreading or deflexed, usually 1–3, conic-ovate or conic-oblong, yellowish brown, unarmed, 2 $\frac{1}{2}$ –3 $\frac{1}{2}$ in. long; apophysis flattened, with a transverse line and slightly or not elevated obtuse umbo; seed $\frac{1}{4}$ in. long. Medit. region.

G.C. II. 22:553; III. 3:629. G.W. 9, pp. 469, 471. H.W. 1:7, pp. 162–5.—Not hardy N. and of little ornamental value, but recommended for seaside planting. Trunk usually slender and destitute of branches for a considerable height: foliage thin and sparse, in tufts

2978. Cone of *Pinus clausa*, grown over by the branch. ($\times \frac{3}{4}$)

at the end of branchlets. Var. *Pityusa*, Gord. (*P. Pityusa*, Stev.), is a smaller tree with slenderer branches, longer lvs., and smaller cones. W. Asia. Var. *brütia*, Henry (*P. brütia*, Ten. *P. eldarica*, Medw. *P. pyrenæica*, David). Lvs. 4–7, rarely 8 in. long, more rigid, bright or dark green: cones sessile, not deflexed, usually in whorls of 2–6, 2–4 in. long with rugose depressed knobs. S. Eu., W. Asia. G.C. III. 4:268. H.W. 1, pp. 172, 173. R.H. 1867, pp. 150, 151.

37. *Pinaster*, Ait. (*P. maritima*, Poir.). CLUSTER PINE. Tree, to 100 ft., with spreading or sometimes pendulous branches forming a pyramidal head: branchlets bright reddish brown: buds oblong-oval, brown, not resinous: lvs. stiff, acute, usually twisted, glossy green, 5–9 in. long: cones short-peduncled, clustered, conic-oblong, light brown and glossy, 4–7 in. long; apophysis pyramidal, conspicuously keeled with prominent triangular, acute umbo; seed grayish brown, $\frac{1}{2}$ in. long. S. Eu., near the coast. Gn. 14, p. 20. G.W. 9, p. 470. H.W. 1, pp. 168, 169.—Handsome pine of regular, pyramidal habit and rapid growth, but not hardy N. In England it is much used for seaside planting and the vars. *Hàmiltonii*, Parl., var. *Lemoniàna*, Endl. (*P. Pinaster Aberdoniæ*, Loud.), and var. *minor*, Loisel., are occasionally cult. in English gardens.

38. *pungens*, Lamb. TABLE MOUNTAIN PINE. POVERTY PINE. Tree, to 30, occasionally to 60 ft., with stout spreading branches forming a broad open often flat-topped head: branchlets light orange: winter buds oblong, obtuse, dark chestnut-brown: lvs. stout, twisted, sharply pointed, dark green, 1 $\frac{1}{4}$ –2 $\frac{1}{2}$ in. long: cones conic-ovate, oblique at the base, light brown, 2 $\frac{1}{2}$ –3 $\frac{1}{2}$ in. long; apophysis pyramidal and conspicuously keeled, the conical elongated umbo ending in a stout curved spine; seed light brown,

2979. *Pinus contorta* ($\times \frac{1}{4}$). No. 42.

$\frac{1}{4}$ in. long. N. J. to N. C. and Tenn. S.S. 11:584.—Hardy as far north as Mass., but of little ornamental value.

39. *clausa*, Vasey (*P. inops* var. *clausa*, Engelm.). SAND PINE. SPRUCE PINE. Figs. 2977, 2978. Tree, to 20, occasionally to 70 ft., with slender spreading

2980. *Pinus rigida* ($\times \frac{1}{2}$). No. 45.

branches: branchlets red-brown: winter buds oblong, obtuse, not or little resinous: lvs. slender and flexible, acute, dark green, 2–3 in. long: cones short-stalked, often oblique at the base, conic-ovate, dark reddish brown, 2–3½ in. long, remaining closed for 3 or 4 years after ripening and occasionally becoming enveloped by the growing wood of the st.; apophysis depressed-pyramidal, conspicuously keeled; umbo with a short, stout spine. Fla. and Ala. near the coast. S.S. 11:582. G.F. 5:161.—Little known in cult., and not hardy N.

40. *virginiana*, Mill. (*P. inops*, Ait.). SCRUB PINE. JERSEY PINE. Tree, to 40, or sometimes to 100 ft., with slender horizontal or pendulous branches in remote and irregular whorls, forming a broad open pyramid or sometimes flat-topped: winter buds oblong, dark brown: lvs. stiff, twisted, spreading, acutish, 1½–2½ in. long: cones conic-oblong, reddish brown, 1½–2½ in. long; apophysis little elevated, with a broad depressed-pyramidal umbo ending in a short recurved prickly; seed pale brown, $\frac{1}{4}$ in. long. N. Y. to S. C., west to Ky. and Ind. S.S. 11:581.—Hardy as far north as Mass., but of little ornamental merit. Valuable in the middle states for covering dry and barren soil.

41. *Banksiana*, Lamb. (*P. divaricata*, Dum.-Cours.). JACK PINE. Tree, to 70 ft., usually lower, sometimes shrubby, with slender spreading branches, forming broad open head: branchlets yellowish to purplish brown: winter buds oblong-ovate, light brown, very resinous: lvs. stiff, twisted, spreading, acute or obtusish, dark or bright green, about 1 in. long: cones conic-oblong, usually curved, pale yellow-brown and lustrous, unarmed, 1½–2 in. long, remaining on the tree for 12–15 years; apophysis flattened, with a transverse line and a small dark obtuse umbo; seed black, $\frac{3}{8}$ in. long. Hudson Bay to N. Y., west to Minn. S.S. 11:583.—The most northern of all American pines and quite hardy, but not of much ornamental value.

42. *contorta*, Douglas (*P. Bolanderi*, Parl. *P. contorta* var. *Bolanderi*, Koehne). SCRUB PINE. Fig. 2979 (adapted from Pacific R. R. Report). Tree, to 20, occasionally to 30 ft., with rather stout branches forming a round-topped compact or open head: branchlets light orange or orange-brown: buds ovate, dark chestnut-brown, resinous: lvs. stiff, twisted, acutish, dark green, 1–2 in. long: cones ovate or conic-ovate, very oblique at the base, often remaining closed for several

years after maturity, 1–2 in. long, light yellowish brown and lustrous, scales of the upper side with elevated, pyramidal apex, the dark umbo ending in a slender incurved spine. Alaska to Calif., and the variety east to Mont. and Colo. G.C. II. 19:45. S.S. 11:567. Var. *latifolia*, Engelm. (*P. contorta* var. *Murrayana*, Engelm. *P. Murrayana*, Balfour. *P. Boursieri*, Carr.), LODGE-POLE PINE, is the form in the Rocky Mts. and a taller tree of pyramidal habit, to 80, or occasionally to 150 ft. tall, with longer, lighter green, 1½–3½ in.-long lvs., less oblique cones. S.S. 11:518. G.C. 1869:191 and R.H. 1869, p. 278 (as *P. Tamrac*). R.H. 1854, p. 226.—In cult., it is usually a bushy low tree and is hardy N., while the typical form is tender.

43. *muricata*, Don. PRICKLE-CONE PINE. Tree, to 50, occasionally to 90 ft., with stout spreading branches forming a regular pyramid in young trees, in old age usually round-topped and compact: branches orange-brown: winter buds ovate, dark brown, resinous: lvs. stiff, usually twisted, acute, dark green, 4–7 in. long: cones usually clustered, oblong-ovate, oblique at the base, chestnut-brown, 2–3½ in. long; scales of the upper side with elongated conical apex terminated by a dark triangular spiny umbo, scales of the lower side more flattened, with slender straight spines; the cones usually remain closed for several years after maturity; seeds almost black, $\frac{1}{4}$ in. long. Calif. S.S. 11:585, 586. G.F. 10:235. F.S. 5, p. 517. G.C. II. 21:48, 49, 53; III. 45:259–61. Gn. 59, p. 129. G.M. 54:977.—Handsome pine, with regular, pyramidal head; not hardy N.

44. *serotina*, Michx. POND PINE. MARSH PINE. Tree, to 50, or occasionally to 80 ft.: branchlets dark orange-color: lvs. 3, rarely 4, slender, dark green, 6–8 in. long, with stomata on all 3 faces: cones subglobose to ovate, short-stalked or nearly sessile, rounded or pointed at the apex, light yellow-brown, 2–2½ in. long, remaining closed for one or two years after maturity; scales thin with depressed apophysis and a small slender, mostly deciduous prickly; seeds with the wing about $\frac{3}{4}$ in. long. N. C. to Fla. S.S. 11:580.—Not hardy N.

45. *rigida*, Mill. PITCH PINE. Figs. 2980–2983. Tree, to 80 ft., with horizontally spreading branches forming an open irregular pyramid: branchlets light brown: winter buds ovate or ovate-oblong, chestnut-brown: lvs. stiff and spreading, acuminate, dark green, 2–5 in. long: cones almost sessile, often in clusters,

2981. *Pinus rigida*, with young cones. ($\times \frac{1}{2}$)

ovate, light brown, 2-4 in. long; apophysis little elevated; umbo triangular, ending in a slender, recurved prickle; seed dark brown, $\frac{1}{4}$ in. long. New Bruns. to Ga., west to Ont. and Ky. S.S. 11:579. G.F. 4:402; 10:195. G.C. III. 44:178. Gn. 31, pp. 128, 132. M.D.G. 1896:301.—Hardy pine of rapid growth when

576. G.C. II. 24:784, 785. G.M. 56:255. F.S. 5, p. 517c.—Of little ornamental value and not hardy N. Usually a bushy tree with sparse dull foliage.

Group 12. MACROCARPÆ.

48. *Côulteri*, Don (*P. macrocarpa*, Lindl.). **PITCH PINE.** Fig. 2965. Tree, to 80 ft., with stout branches, pendulous below and ascending above, forming a loose pyramidal head: winterbuds oblong-ovate, resinous: lvs. stout, acuminate, dark bluish green, 6-12 in. long: cones short-stalked, pendent, cylindric-ovate, yellowish brown, 9-14 in. long; apophysis elongated-pyramidal, narrowed into the compressed spiny-tipped straight or incurved umbo. Calif. S.S. 11:571, 572. G.C. II. 23:409, 413; III. 4:765.—Not hardy N. Old trees are often very picturesque and the large cones are conspicuous and ornamental.

49. *Sabiniana*, Douglas. **DIGGER PINE. BULL PINE.** Fig. 2984 (adapted from Pacific R. R. Report). Tree, to 50 or occasionally 80 ft., usually divided into several sts. with short crooked branches, the lower ones pendent, the upper ones ascending, forming a round-topped head: lvs. slender, flexible, pale bluish green, 8-12 in. long: cones pendent on about 2-in.-long stalks, oblong-ovate, light red-brown, 6-10 in. long; apophysis pyramidal, sharply keeled, flattened at the straight or incurved apex, the lower scales with much-recurved apex; seeds $\frac{3}{4}$ in. long, short-winged. Calif. S.S. 11:569. G.C. III. 4:43; 5:45. F. S. 9:964.—Not hardy N. Distinct pine of loose habit and with sparse pale foliage. The seeds are edible.

2984. *Pinus Sabiniana*. (Cone $\times \frac{1}{4}$, leaves and seed $\times \frac{1}{2}$)

young and easily raised from seed; grows on dry and sterile soil. As an ornamental plant it may be used on dry and rocky slopes, where it becomes often very picturesque when older. It sprouts readily from stumps if cut down or destroyed by fire, but the sprouts are short-lived and never develop into trees.

46. *radiata*, Don (*P. insignis*, Douglas. *P. montereyensis*, Hort.). **MONTREY PINE.** Fig. 2965. Tree, to 80 or 100 ft., with stout spreading branches forming an irregular open, round-topped head: bark thick, furrowed: branchlets brown: buds ovate, bright chestnut-brown: lvs. acute, bright green, 4-6 in. long: cones short-stalked, conic-ovate, upper scales with elevated, rounded, almost hemispherical and obscurely keeled apex; umbo small, with minute straight or recurved prickle, lower scales with almost flattened apex; seed black, $\frac{1}{4}$ in. long. S. Calif. S.S. 11:573, 574. F.S. 6, p. 44. G.C. III. 9:336, 341; 38:435. G. 12:263; 22:131. R.H. 1906, p. 154. Gn. 36, p. 47; 49, p. 312.—Handsome species with bright green foliage and of rapid growth and bushy habit when young; valuable for seaside planting. Not hardy N.

47. *attenuata*, Lemm. (*P. tuberculata*, Gord., not Don. *P. californica*, Hartw., not Loisel.). **KNOT-CONE PINE.** Tree, usually 20, occasionally to 100 ft., with slender horizontal branches ascending at the ends, forming a broad pyramid, with open round-topped head in old age: bark thin, scaly: young branches slender, dark orange-brown: winter buds oblong-ovate, dark brown: lvs. slender, acuminate, pale yellowish or bluish green, 3-7, usually 4-5 in. long: cones short-stalked, usually in clusters, elongated-conical, $3\frac{1}{2}$ -6 in. long, upper scales with pyramidal apex; umbo prominent, sharply pointed and recurved, lower scales with depressed apex and small prickly umbo; seed $\frac{1}{4}$ in. long. Ore. to Calif. S.S. 11:575,

2983. Old cone of pitch pine.—*Pinus rigida*. ($\times \frac{1}{2}$)

50. *Torreyana*, Carr. **SOLEDAD PINE.** Tree, to 40, or occasionally to 60 ft., with spreading and sometimes ascending branches: branchlets greenish or purplish, bloomy, glabrous: lvs. rigid, dark green, 8-13 in. long: cones broadly ovate, 4-6 in. long, chocolate-brown; apophysis low-pyramidal; umbo elongated and reflexed with short spiny tip; seeds $\frac{3}{4}$ in. long, short-winged. S. Calif. S.S. 11:557, 558.—Rarely cult.; not hardy N.

P. Abies, Linn.—*Picea excelsa*.—*P. albicaulis*, Engelm. Pyramidal tree, to 30, rarely 60 ft., sometimes shrubby, allied to *P. flexilis*: bark whitish or light brown: cones smaller, $1\frac{1}{2}$ -3 $\frac{1}{2}$ in., subglobose or oval, purplish brown. Brit. Col. to Calif. and Wyo. S.S. 11:548. G.C. II. 24:9. Probably as hardy as *P. flexilis*.—*P. arizonica*, Engelm. (*P. ponderosa* var. *arizonica*, Shaw). Tree, to 100 ft. with pyramidal or open round-topped head, allied to *P. ponderosa*: lvs. shorter, 5-7 in. long: cones smaller, 2-2 $\frac{1}{2}$ in., with recurved spines. Ariz. S.S. 11:559.—*P. chihuahuana*, Engelm.—*P. leiophylla* var. *chihuahuana*.—*P. Gerardiana*, Wall. Tree, to 60 ft., with broad round-topped head, allied to *P. Bungeana*: lvs. bluish green, 2 $\frac{1}{2}$ -4 in. long: cones 6-9 in. long, with the tips of scales reflexed; seeds short-winged, to 1 in. long, edible. Himalayas. Not hardy N.—*P. glabra*, Walt. **CEDAR PINE. SPRUCE PINE.** Pyramidal tree, to 80, rarely 120 ft., allied to *P. echinata*: lvs. dark green, $1\frac{1}{4}$ -3 in. long: cones broadly to oblong-ovate, $1\frac{1}{4}$ -2 in. long. S. C. to Fla. and La. S.S. 11:583. Hardy only S.—*P. Gordoniana*, Hartw.—*P. Montezumæ*.—*P. Grenvilleæ*, Gord.—*P. Montezumæ*.—*P. Heldreichii*, Christ. Small

tree, allied to *P. nigra*: lvs. 3-4 in. long; cone 3 in. long, with impressed dull umbo furnished with a small curved prick. Greece. G.C. II. 21:740.—*P. insularis*, Endl. Tall tree: lvs. 3, flaccid and very slender, 7-9 in. long; cones conic-ovate, $2\frac{1}{2}$ -3 in. long; scales with low pyramidal, sharply keeled apex and obtuse or on the upper scales mucronulate umbo. Philippine Isls. Not yet intro.—*P. latifolia*, Sarg. (P. Mayriana, Sudw.) Tree, to 60 ft., allied to *P. ponderosa*: lvs. 12-15 in. long and $\frac{1}{2}$ in. wide: cones oblique at the base, 3-4 in. long. Ariz. S.S. 11:565. G.F. 2:496; 8:25. Not hardy N.—*P. latissima*, Engelm.—*P. Pincana*.—*P. leiophylla*, Schlecht. & Cham. Allied to *P. Lambertiana*. Tall tree: lvs. usually 5, slender, grayish green, 4-6 in. long; cones ovoid, nearly symmetrical, 2-3 in. long, with small recurved prickles. Mex. Var. *chihuahuana*, Shaw (P. chihuahuana, Engelm.). Lvs. usually 3 or 4, stouter and shorter. Calif. to New Mex. and Mex. S.S. 11:566. G.F. 8:24.—*P. macrophylla*, Lindl., not Engelm.—*P. Montezumae*.—*P. Mayridna*, Sudw.—*P. latifolia*.—*P. Montezumae*, Lamb. (P. Gordoniana, Hartw. P. Grenville, Gord. P. macrophylla, Lindl., not Engelm.). Tree, to 80 ft. and more: allied to *P. Torreyana*: lvs. glaucous or green, 7-16 in. long; cones 4-14 in. long, light brown; apophysis depressed pyramidal, with a short, recurved spine. Mex. G.C. III. 8:465-7, 475; 15:271, 273. Gn. 56, p. 481; 58, p. 397. Very variable species, as the numerous (about 70) synonyms show. Not hardy N.—*P. Nelsonii*, Shaw. Allied to *P. cembroides*. Low bushy tree to 30 ft.: lvs. with persistent sheaths 3, $2\frac{1}{2}$ - $3\frac{1}{2}$ in. long, serrulate: cones on stout curved peduncles, cylindrical; seeds wingless. Mex. G.C. III. 36:122; 37:306.—*P. patula*, Schiede. Allied to *P. Teda*. Tree, to 80 ft.: lvs. sometimes 4 or 5, drooping, light green, 7-9 in. long; cones oblong-ovate, oblique with depressed knobs, 4 in. long. Mex. G.C. II. 23:108, 109, 117; III. 9:435. Graceful tree, but not hardy N.—*P. Picea*, Linn.—*Abies Picea*.—*P. Pincana*, Gord. (P. latissima, Engelm.). Allied to *P. cembroides*. Low tree with slender branches: lvs. usually 3, entire, 5-6 in. long; cones oblong-ovate, long-stalked, $2\frac{1}{2}$ - $3\frac{1}{2}$ in. long; seeds wingless. Mex. G.C. II. 18:713; III. 38:122.—*P. pumila*, Regel (P. Cembra var. pumila, Fall.). Shrubby, often procumbent, allied to *P. Cembra*, but resin-ducts of lvs. external: lvs. $1\frac{1}{2}$ -3 in. long; cone $1\frac{1}{2}$ in. long; seed $\frac{1}{2}$ in. long. N.E. Siberia to Japan. Hardy. S.I.F. 2:1. G.C. III. 46:193. M.D. 1912, pp. 159, 161.

ALFRED REHDER.

PIPER (the ancient Latin name). *Piperaceæ*. **PEPPER**. A vast genus (probably 600 to 700 species) of both the Old and New Worlds, mostly in the tropics, a few of which are in cultivation as greenhouse foliage subjects and in collections of economic plants.

Pipers are mostly dioecious: erect or climbing woody plants, or sometimes herbaceous, and some are trees: fls. very minute, borne beneath decurrent bracts in slender, erect or drooping axillary spikes or catkins; perianth none; stamens usually 1-4; ovary 1-loculed, with a solitary erect ovule: fr. a small globular drupe or berry: lvs. alternate, stipulate, usually entire. The pepper of commerce is the product of *P. nigrum*. The family contains many plants with aromatic, pungent and stimulating qualities. Some of them are used in medicine, and others yield intoxicating and masticatory products. For red pepper and chili or chile pepper, see *Capsicum* and *Pepper*. To this genus are also referred *Enckea* and species sometimes grown under the name of *Chavica*.

In choice collections, one is likely to find several species, but as they seldom fruit it is very difficult to determine their species. In the following list are all the names that have appeared in the American trade. Piper is an exceedingly difficult genus to the systematist because of the great numbers of species, the variation of foliage in the same plant at different epochs, the difficulty of matching the sexes of the same species, the imperfect specimens in herbaria, and the scarcity of good studies of the plants in the wild. They are easy of cultivation. Most of those known in houses require a warmhouse temperature and a humid atmosphere. Easily multiplied by cuttings of the firm wood. They are grown for the decorative value of their drooping or bushy sprays.

A. Plant erect, and bushy or arboreous.

excelsum, Forst. (*Macropiper excelsum*, Miq.; see p. 1962, Vol. IV). Glabrous shrub, reaching 20 ft. in some of its native places: lvs. aromatic, cordate-obicular to ovate, stalked, short-acuminate, 7-9-nerved from the base, the blade 2-4 in. across: spikes short-peduncled, the staminate ones 2-3 in. long and the bracts peltate, the stamens 2 or 3; pistillate spikes shorter, the fls. usually with 3 stigmas. New Zeal. and other S. Pacific islands.—Offered in Calif. A form with yellow-

blotched or cream-colored foliage is known as var. *aureo-pictum*.

methysticum, Forst. (*P. inebrians*, Soland. *Macropiper methysticum*, Hook & Arn.). Dioecious shrub, 8-10 ft., nearly glabrous: lvs. round-oval, deeply cordate at base, acuminate at apex, slightly pubescent beneath on the nerves and on the short petiole: spikes mostly shorter than the lvs. and opposite them. Pacific islands.—From the root of this plant is made the drink known as kava, ava, yaquona.

geniculatum, Swartz (*Artanthe geniculata*, Miq.). Shrub with swollen nodes, the branchlets glabrous: lvs. oblong or oblong-lanceolate, mostly acuminate, with several pairs of prominent veins, the petioles canaliculate: spikes or catkins 3-5 in. long, on peduncles as long as the petioles. W. Indies, S. Amer.—Offered in S. Calif.

AA. Plant climbing, or drooping when not given support.

B. Lvs. ovate-lanceolate, deciduous.

Futokadsura, Sieb. **JAPANESE PEPPER**. Clinging closely to walls by its aerial roots: lvs. ovate-lanceolate and acuminate, cordate at base, glabrous: fls. greenish: berries globose, red or brownish. Japan.—Handsome plant, withstanding considerable frost.

BB. Lvs. broadly ovate or roundish, evergreen.

nigrum, Linn. **BLACK PEPPER**. Plant woody below: st. strong, terete, emitting roots, tall-climbing, glabrous: lvs. thickish, stalked, broadly ovate-oblong or nearly orbicular, the base usually rounded and oblique, 5-9-nerved above the base, the nerves alternate: fls. sometimes polygamous but usually dioecious: fr. globose, red. Old World tropics, but now widely dispersed in warm countries. B.M. 3139.—Sometimes grown in hothouses, particularly amongst collections of economic plants. In the wild it is a strong climber, rooting at the nodes, sometimes reaching 20 ft. in height. It is reported as hardy at Santa Barbara, blooming but not fruiting. The dried berries, which are collected before ripe, are black and wrinkled, and constitute the black pepper of commerce. When the outer skin is removed from the ripe fruit, the product is white pepper. The commercial pepper comes mostly from eastern tropics.

Cubéba, Linn. (*Cubéba officinalis*, Raf.). **CUBEB**. Climbing or tree-like: lvs. glabrous, oval, short-acuminate, obliquely cordate, the upper ones smaller and oval-oblong, somewhat unlike on plants of the different sexes: peduncle glabrous, about the length of petiole or somewhat surpassing it; stigmas 4: fr. a subglobose somewhat apiculate stalked berry, resembling that of *P. nigrum*. E. Indies.—The fr. is employed in medicine.

ornatum, N. E. Br. Climbing, 10-15 ft. tall, glabrous, rooting at nodes: lvs. glabrous "and directed to one side;" petioles slender and nearly terete, the blade peltate, ovate-orbicular, with a short, rather blunt point, the nerves 7 but not prominent above and uniting in loops on the margin, the upper surface of the young lvs. shining green and covered with pinkish spots, the old lvs. duller and whiter-spotted. Celebes.

P. Bitle, Linn. **BETEL** (which see, p. 496). Climbing, nearly or quite glabrous: lvs. large and thick, ovate-oblong, acuminate, usually oblique at base, strongly 5-7-nerved: spikes often 4-6 in. long: fr. very fleshy, often cohering into a long-cylindrical mass. Eastern tropics. B.M. 3132. Lvs. of this and others chewed by natives with the betel-nut.—*P. metallicum*, Hort. (Hallier?). Lvs. thick, rounded, handsome metallic green. Borneo.—*P. officinarum*, C. DC. (*Chavica officinarum*, Hort.?) has long-elliptic somewhat sharp-pointed feather-veined coriaceous lvs. and globular united berries in a dense spike. India and Malaya.—*P. porphyphyllum*, N. E. Br. (*Cissus porphyphylla*, Lindl., and of horticulturists). Handsome climbing foliage plant with broadly cordate-oval short-pointed lvs. that are purple beneath and bronzy green and pink-spotted along the veins above. Probably E. Indies. F.S. 14:1491. R.H. 1883, p. 560. Lowe, 59.—*P. rubronoddsum*, Bull. Shrub, with red-jointed roughish sts.: lvs. cordate-ovate, somewhat blistered, silvery gray, the petiole pubescent. Colombia.—*P. rubrovenosum*, Hort. Climbing: lvs. cordate-ovate, acuminate, marked with rose-colored dots and streaks along the veins. Very like *P. ornatum*, and perhaps not distinct. Papua. I.H. 34:33.

L. H. B.

PIPSISSEWA: *Chimaphila*.

PIPTADÈNIA (Greek, *falling gland*; meaning obscure). *Leguminosæ*. About 45 species of shrubs or trees, mostly native to S. and Cent. Amer., a few in the tropics of the Old World, similar to *Mimosa* and *Acacia*: lvs. bipinnate with numerous small lfts., rarely with few and large lfts.: fls. small, white, in axillary globose heads or cylindrical spikes; petals small, equal, connate to the middle; stamens 10, free: pod broadly linear, 2-valved, not septate within and not pulposus. The following species has been intro. to Calif. by Franceschi chiefly for its economic interest; in its native country it is valued for tan bark. Prop. by seeds. **P. Cebil**, Griseb. (*P. macrocarpa* var. *Cebil*, Chodat & Hassler). Tree, to 60 ft., glabrous: lvs. with 10-16 pairs of opposite pinnæ, each with 24-40 pairs of linear-oblong acutish lfts. about $\frac{1}{2}$ in. long; petiole about 1 in. long with a conspicuous gland near the middle: fl. heads globose, axillary, 1-4, $\frac{1}{2}$ in. across, on slender pedicels $\frac{3}{4}$ -1 in. long; stamens long-exserted: pod 6-8 in. long, about $\frac{3}{4}$ in. wide, sinuate between the seeds. Argentina.

The following three species have been recently intro. by the Dept. of Agric.: *P. comminis*, Benth. (*Acacia gonocantha*, Mart.). Prickly tree or shrub sometimes sarmentose: branchlets puberulous, angled, older branches sometimes developing corky wings; prickles small: lvs. with 5-12 pairs of pinnæ, each with many oblique, falcate, linear lfts.: fl.-spikes 2-3 in. long, solitary or 2-3 in the axils or sometimes crowded at the end of the branches; ovary glabrous: pod linear, 3-4 in. long, reticulate, with scarcely thickened margin. Brazil. Fl. Brazil. 15, 2:74.—*P. macrocarpa*, Benth. (*Acacia grata*, Willd.). Unarmed tree: branchlets and petioles grayish tomentulose: lvs. about 6 in. long, with 10-25 pairs of pinnæ, each with many oblique linear lfts. scarcely 1 line long: fl. heads peduncled, globose, many-fld., 2-4, axillary, sometimes crowded at the end of the branchlets: pod 4-10 in. long, $\frac{3}{4}$ -1 in. broad, with thickened margin. Brazil, Bolivia.—*P. rigida*, Benth. (*Acacia Angico*, Mart.). Unarmed tree or shrub, nearly glabrous: lvs. with 3-6 pairs of pinnæ, each with many oblique linear, falcate, lustrous lfts. about $\frac{1}{2}$ in. long: fl.-spikes axillary, 1-1 $\frac{1}{2}$ in. long; ovary glabrous: pod linear, to 5 in. long, with slightly thickened margin. Brazil. It furnishes the Angico gum similar to gum arabic; the bark is rich in tannin.

Other species, known as acacias, are likely to appear in cult. *P. chrysostachys*, Benth. (*Acacia chrysostachys*, Sweet). Unarmed tree, puberulous: pinnæ 3-6 pairs; lfts. 8-15 pairs, oblong, obtuse, nearly $\frac{1}{2}$ in. long: spikes solitary or 2, dense, 3 in. long; calyx and corolla grayish pubescent. Madagascar. The wood is used by the natives for musical instruments.—*P. latifolia*, Benth. (*Acacia frutescens*, Mart.). To 4 ft. high: lvs. bipinnate, glabrous, with 2 or 3 obovate-elliptic lfts.: fl.-spikes axillary, or terminal panicles. Brazil.—*P. peregrina*, Benth. The *Acacia microphylla*, Willd., is referred here. It is unarmed: pinnæ 25 pairs; lfts. 50-60 pairs, linear, acute, ciliate; large gland at base of petiole: branches and petioles pubescent: heads pedunculate, twin, in the axils: pod linear, 9 in. long. Brazil to Trinidad.

ALFRED REHDER.†

PIPTÁNTHUS (Greek, *to fall*, and *a flower*; the teeth of the calyx, petals, and stamens fall off soon). *Leguminosæ*. Two shrubs natives of the mountains of southern Asia, grown for ornament.

Plants 3-10 ft. high: lvs. digitately 3-foliate: fls. racemose, bracted; calyx campanulate, 5-toothed; teeth equal, lanceolate; corolla 3 times longer than the calyx; petals all with long claws; standard orbicular, erect, margins reflexed; wings obovate; keel obovate-oblong, connate down the back, slightly incurved; stamens free; anthers uniform; ovary linear, stalked, downy, 6-10-ovuled; style filiform, incurved; stigma minute, terminal: pod linear, flattened, continuous within. Closely related to *Baptisia* and *Thermopsis*, from which it is at once distinguished by having its stipules opposite-connate instead of free or wanting as in those genera. As yet but little known in U. S.

A. Lvs. glabrate on both sides.

nepalensis, D. Don (*Baptisia nepalensis*, Hook. *Thermopsis nepalensis*, DC.). Shrub 6-10 ft. tall: branches downy: stipules small, connate; petiole 1 in. or less; lfts. glabrescent, lanceolate, 2-4 in. long, narrowed to both ends: fls. 12-20 in rather dense racemes; bracts large, deciduous; calyx downy, deciduous from the base; corolla yellow, 1 in. or more long: pod 2-5 in. long, 3-10-seeded. Temperate slopes of Himalayas,

7,000-9,000 ft., and in Yunnan. R.H. 1914, p. 9. G.C. III. 43:178. J.H. III. 43:250. H.U. 1:260.—An attractive ornamental of the habit of *laburnum*. Flowers in May in the Middle States. Recently re-intro. from W. China; probably not hardy north of Washington, D. C. Prop. is by seeds sown in spring; if sown early in the greenhouse, the plants will sometimes bloom the same year; also prop. by soft-wood cuttings under glass in spring or early summer.

AA. Lvs. reddish tomentose beneath, silky above and becoming glabrate.

tomentosus, Franch. Slender shrub 3-7 ft. tall: young branches tomentose, brownish glabrescent with age: lfts. ovate to ovate-lanceolate, before flowering silky-white above, beneath pale reddish tomentose, nearly glabrous above with age: fls. similar to the above species but calyx with long silky hairs and sepals more acuminate: pod narrowly linear, about $\frac{1}{4}$ in. wide and 2-3 $\frac{1}{2}$ in. long, at maturity densely short-tomentose, 5-8-seeded. Wooded mountain slopes of Yunnan, China.—More beautiful and much more hardy than *P. nepalensis*, producing an abundance of fls. in April to May in the Middle States. Its white silky hairs give it a distinctive silvery appearance.

P. L. RICKER.

PIPTÛRUS (Greek, *fallen tail*, in allusion to the inflorescence of some species). *Urticaceæ*. Erect, dioecious trees or shrubs: lvs. alternate, 3- or 5-nerved; stipules bifid: fls. in axillary clusters or the clusters spicately arranged; male fls., perianth 4-5-fid, lobes valvate; stamens 4 or 5; female fls. on a somewhat fleshy receptacle, perianth ovoid, narrowed to a minute mouth; ovary adherent to the perianth: achenes small, surrounded by the accrescent fleshy perianths, forming a soft and fleshy fruit.—About 12 species, Mascarene Isls. to Malaya, Austral., and Polynesia. **P. argenteus**, Wedd. Tree, 18-20 ft.: lvs. up to 8 in. long and 4 in. broad, oval-acuminate, recurved at the top, entire, dark green with silvery white marking on the upper surface, silvery white on the under surface: fls. in sessile glomerules, inconspicuous. Malaya, Austral., and Polynesia. G.W. 7, p. 111. This has been intro. in botanic gardens.

PIQUERIA (A. Piquer, Spanish physician of 18th century). *Compositæ*. Under the name of *Stevia serrata* or *S. serratifolia*, florists grow *Piqueria trinervia*, Cav. (Fig. 2985), for its small white fragrant fls. and for bedding. It is native in Mex., Cent. Amer., and Hayti. It is perennial. The genus contains about 20 species of herbs or bushes, all of Trop. Amer. They have exclusively tubular fls. in densely cymose heads, the heads containing 3-5 whitish fls.; torus plane or convex, naked; pappus none or very short: achene 4-5-angled. It resembles a small eupatorium in foliage and fls. The small heads are borne in small paniced corymbs, each cluster terminating a slender axillary branch or peduncle. The lvs. are opposite, lanceolate to oblong-lanceolate, serrate-dentate, very short-stalked. There is a dwarf, compact form, var. **nana**, Hort., and also one with broadly white-edged lvs., var. **variegata**, Hort., Fig. 2986, which are much used for bedding out. The Cent. American var. **luxurians**, O. Kuntze, has slightly larger heads but does not appear to have been intro. into

2985. *Piqueria trinervia*. Known to florists as *Stevia serrata*. ($\times \frac{1}{2}$)

horticulture. The piqueria endures both sun and shade, and thrives with even indifferent treatment. For fls. it is much prized in winter, when delicate white sprays are not abundant. It demands the general treatment given zonal geraniums. Prop. by cuttings with great ease, and may begin to bloom when only 2 or 3 in. high. It often blooms in the cutting-bed. It also grows readily from seeds, which are handled by seedsmen. Frequent pinching will keep the plants within bounds and contribute to floriferousness. Plants allowed to grow as they will soon become straggly and wiry. For winter bloom the plants may be handled in pots or grown in beds. A stock of compact pot-plants kept in a cool corner is very useful for filling vacancies in the house.

2986. Marginate form of
Piqueria trinervia.

Cultivation of piqueria (by Wm. Scott).—Usually the best way to produce good flowering plants of stevia in midwinter is to save a few old plants after the flowers are cut at New Years. Cut off the old stems 5 or 6 inches above the pots and stand the plants in any cool house. The plant needs the coolest house at all times; 40° at night during the winter will grow it better than a higher temperature, but, for all that, it does not endure the slightest frost. About March 1, these old plants will have sent out any number of small growths from the base of the stems. These root very readily in a cool propagating-house. They should then be grown along, first in 2- and afterward in 3-inch pots, until the first of June, when they should be planted out in the open ground. It need not be very rich ground, for they are very rampant growers. Give every plant 2 feet of space. They seldom need any artificial watering in summer, but they should have frequent pinching to produce bushy plants. The more shoots, the more flowers will be secured. Before there is any danger of frost in the fall, the plants should be lifted and put into 6-, 7-, or 8-inch pots. They lift well, and if stood in the shade and kept syringed for a few days they will show no bad results of the lifting. A position at the north side of a shed or wall is much better for them for the next month than under glass, but always have them in a position where they can be protected in case of a frost. By the end of October, if frost is escaped, put them in the lightest and coolest house available. If kept cool the very desirable sprays of flowers will be in perfection at Christmas, and that is the time they are most valuable. Although classed as a common cheap flower, there is a grace about stevias that makes them indispensable for many flower arrangements.

L. H. B.

PIRCÛNIA: *Phytolacca*.

PISCÍDIA (Latin for fish and kill). *Leguminosæ*. One or 2 species, including the fish-poison tree of the American tropics, or Jamaica dogwood. The lvs., bark, and twigs of this tree when thrown into the water intoxicate or stun the fish so that they can be caught readily. (For the plant used in China for this purpose, see *Cocculus*.) The bark has also been used in medicine for its hypnotic effect. Botanically this genus is close

to *Lonchocarpus*, differing mainly in the pod, which is long, thickish, and longitudinally 4-winged: calyx-teeth 5, short, broad: wings adhering to the falcate keel; vexillar stamen free at the very base, but grown together at the middle with the others into a closed tube; ovary sessile, many-ovuled.

Erythrina, Linn. (*P. piscipula*, Sarg. *Erythrina piscipula*, Linn. *Ichthyomethia piscipula*, Hitchc.). FISH-POISON TREE. JAMAICA Dogwood. Lfts. 7-11, opposite, oblong or elliptical, pointed or blunt: fls. purplish white, ½ in. across: pod 2-4 in. long, 4 lines broad; seeds 6-8, black. Trop. Amer., especially common in Jamaica.

P. L. RICKER.

PISÓNIA (named after Willem Piso, a physician and naturalist of Amsterdam, who died in 1648). *Nyctaginaceæ*. Erect or rarely subscandent trees and shrubs: lvs. opposite or subverticillate: infl. terminal, axillary or lateral clusters; fls. diœcious, rarely monœcious or hermaphrodite, pink, greenish or yellow; perianth 5-toothed; stamens 6-10; ovary elongate-ovoid, sessile: fr. an elongated utricle often bearing at its base the persistent filaments enveloped in the calyx and becoming fleshy, smooth or covered with spiny glands. About 80 species, mostly natives of Trop. and Subtrop. Amer. but a few in Asia, in the Mascarene Isls., and Polynesia. *P. Brunoniâna*, Endl. A tree reaching a height of nearly 50 ft.: lvs. alternate, oval-oblong, up to 10 in. long and 4 in. broad, acuminate, entire or sinuate; petiole somewhat thick, up to 1 in. long; fls. very inconspicuous in spreading terminal cymes. Tahiti and Marquesas Isls. Intro. in Belgian gardens. This species has been referred to both *P. umbellifera*, Forst., and *P. inermis*, Forst., not Jacq. The most recent treatment by Rock, "The Indigenous Trees of the Hawaiian Islands," regards it as a synonym of *P. inermis*. The following species are also reported as having been in cult.: *P. aculeata*, Linn., *P. inermis*, Forst., not Jacq. (*P. grândis*, R. Br.), and *P. obtusata*, Jacq., but apparently are not now grown.

PISTÁCIA (derived indirectly from ancient Persian *pista*). *Anacardiaceæ*. Trees or shrubs which exude turpentine or mastic. One species of the genus, *P. vera*, produces the pistachio-nuts or pistache of commerce which are used in confectionery and flavoring, and some of the other species are used for ornamental planting and as stock on which to graft the commercial species.

Leaves alternate, evergreen or deciduous, 3-lvd. or even- or uneven-pinnate: infl. paniculate or axillary, racemose; fls. small, diœcious and without petals; males with 5-divided or -parted calyx and 5 stamens; females with 3-4-divided or -parted calyx, short 3-divided style and 1-celled ovary: fr. a dry drupe.—About 20 species, Medit. region to Asia, with one species from the Canaries, and one from Mex., which has also been found in Calif. The so-called nut of Pistacia is really the seed or kernel of a dry drupe. The seed is green, and has a highly peculiar flavor. *P. Terebinthus* exudes from its st. the fragrant Cyprian or Scio-turpentine used in medicine as early as the time of Hippocrates.

Cultivation of the pistachio, or pistache. (G. P. Rixford.)

Several species of Pistacia, *P. vera*, *P. atlantica*, *P. Lentiscus*, *P. mutica*, *P. Terebinthus*, *P. chinensis*, *P. mexicana*, *P. integerrima*, and *P. verestina*, a hybrid, have been introduced into this country by the Office of Foreign Seed and Plant Introduction of the United States Department of Agriculture and are being tested as stocks upon which to work the best varieties of *P. vera*. The cultivated species of pistache is indigenous to Asia Minor, Syria, and Palestine. It was first brought to Rome, according to Pliny, by Vitellius, then governor of Syria, during the reign of Tiberius early in the first century of the Christian era and was then carried to

Spain by Flavius Pompeius. The first introduction into the United States dates from an importation of nuts by the Federal Patent Office in 1853-1854. These nuts were widely distributed throughout the middle and southern states but do not seem to have attracted much attention until trees were introduced into California by the writer, from southern France in 1876, and subsequently by the United States Department of Agriculture at various times up to the present.

The best named varieties, a half-dozen in number, have been imported from Syria, Sicily, and other Mediterranean countries and have been extensively propagated at the Government stations, chiefly at Chico, California. During the past seven or eight years, budded trees of the named varieties and seedlings of various species to the extent of 25,000 or 30,000 have been distributed to sections of the southwestern states, chiefly California. The best nuts in market are from the island of Sicily, where wild *Terebinthus* trees are thinned out and grafted with *P. vera* cions.

In this country, the tree is propagated by either budding or grafting. In nursery rows the stocks are budded when one year old. One experienced nurseryman has best success by the use of dormant buds from old wood inserted in April or May when the bark peels freely. He sometimes takes buds in winter and keeps them in cold storage until ready for use. All the species mentioned above are successfully used for stocks, some, however, give the preference to *P. Terebinthus*, *P. vera*, *P. mutica*, and *P. atlantica*.

The trees may be worked either in nursery or in the orchard when the seedlings are well established. In planting the orchard, it is best to put out trees one year from the bud or one or two years from the seed, as the tap-root is large and young trees are most successfully moved.

It is suggested that one form of the commonly cultivated pepper tree, *Schinus terebinthifolius*, is so closely related to the pistache that it may be used as a stock for *P. vera*. The vigor, hardiness, and rapid growth of *P. chinensis* seemed to indicate it as an ideal stock upon which to work *P. vera*; but the growth of the bud the first year was a disappointment, as when it began to grow the stock in most cases stopped, resulting, at the end of the season, in a top-heavy tree, frequently $\frac{3}{4}$ inch above and $\frac{1}{2}$ inch below the union. However, the second or third year, the stock overtakes the bud, so that the only precaution required is to stake the tree the first year or two.

The pistache is a dry-climate tree, somewhat harder than the fig and olive. When once established in good deep soil, little irrigation is required. It flourishes in the southwestern states wherever the climate permits the growth of the olive. The trees are planted 25 feet apart, and one male to six or seven females must be put out as pollinizers. The males of *P. vera* blossom first and in some countries these flowers are gathered and preserved in a dry place until the female flowers open; the pollen is then dusted over them. Sometimes twigs of staminate flowers are cut from the tree and pushed into pots of moist earth where they will keep fresh a few days until the pistillate flowers open. *P. atlantica* male flowers open earlier than the female flowers of *P. vera* and have served as good pollinizers for the latter. In that case, of course, the seeds of such crosses, if planted, would produce hybrid trees. Sometimes the male cions are grafted into female trees. The male trees are invariably larger and more vigorous than the females.

The grafts begin to bear the fourth year, and at the age of eight to ten years, with good care, should yield twenty-five to one hundred pounds of nuts in the shell, of which it takes three pounds to make one of shelled kernels, in which form most of them are imported. There are seedling trees in California eight and nine years of age which are producing annually twenty to

twenty-five pounds of nuts. It is the highest-priced nut in our markets, selling at wholesale from 35 to 75 cents a pound. It is a curious fact, not mentioned by botanists, that the shells grow to about normal size and remain empty if not pollinized. After pollination the ovule rapidly expands and fills the shell.

In central California, seeds are planted in March. The seeds should be soaked over night in lye-water made with a can of lye to twenty gallons of water; then put into a coarse sieve and rub with a piece of burlap to remove the pulp. If this is not done, the seeds will be long in germinating. Plant in good soil in house or hotbed.

The pistache nut is greatly appreciated in the countries bordering on the Mediterranean, especially in Syria, where it is extensively used, as is the almond and walnut in this country. In Syria it always forms an important ingredient of all wedding feasts. The parting guest after a social call is always provided with a bag of nuts. At present, in this country, owing to the high price, its use is restricted to confectioners who use it for coloring and flavoring. When processed as are salted almonds, but in the shell, they are widely liked. The dehiscent shell is penetrated by the salt-water, while the crack facilitates the opening by the fingernails. It is not presumed that growing the nuts will become an important industry; still, as the tree is a good bearer and thrives in hot arid regions where the filbert and walnut cannot be grown, it will probably have a place in nut-production not now occupied by other species. It is not segregated by the customs authorities from other nuts, but dealers estimate the annual importations into the United States at a value of \$250,000.

The cultivated species of Pistacia.

Terebinthus, Linn. A small tree: lvs. deciduous; lfts. 9-13, mucronate; the petiole slightly winged; fls. small, in axillary panicles; stamens purplish; stigmas red: fr. small, orbicular, slightly flattened, dark purple, and wrinkled. Medit. region.—It produces a transparent gum from incisions, and in hot countries it exhales a penetrating resinous odor in the evening.

atlantica, Desf. Tree up to 60 ft. in height and 12 ft. circumference: lvs. deciduous, odd-pinnate; lfts. 7-11, alternate, lanceolate, obtuse, glabrous and sessile; petiole narrow-winged; pistillate fls. in loose, axillary racemes; staminate fls. axillary and more compact. Sahara region.—It exudes a gum similar to that of *P. Lentiscus* and *P. Terebinthus*. Its heartwood is brown, resembling walnut. Preferred by some as stock for *P. vera*.

chinensis, Bunge. CHINESE PISTACHIO. Tree, 50-60 ft. high: lvs. deciduous, odd-pinnate; lfts. 5-6 pairs, short-petiolate, lanceolate: infl. compositely branched panicles: fr. an obovoid-rotundate drupe, compressed and about $\frac{1}{4}$ in. long and broad, scarlet turning purplish. China.—Used as stock for *P. vera* and also said to be a good shade tree in Fla. and useful for ornamental planting, being rapid-growing and the foliage coloring finely in the late fall.

integerrima, Stew. Medium-sized tree: lvs. aromatic, even- or uneven-pinnate, finely pubescent when young; lfts. 4-5 pairs, usually opposite, lanceolate from an oblique base; the petiole very short; drupe broader than long, $\frac{1}{4}$ in. diam. March-May. Himalayas.—Yields the zebra wood of India. It is said that the seeds must pass through the intestines of a fowl before they will germinate; tree also said to have promise as an ornamental and perhaps even as a timber tree in some parts of the S. W. Little known in cult.

Lentiscus, Linn. Small evergreen tree, often shrubby, up to 12-15 ft.: lvs. even-pinnate with winged petioles; lfts. 3-5 pairs, coriaceous, glossy green above, light green below, ovate, obtuse: drupe about 1 in. diam., orbicular, slightly apiculate, reddish finally black at maturity. Medit. region.—In Algeria, it forms dense

copses along the coast of 15,000 hectares in extent. It is the mastic tree of the island of Chios. The gum is obtained by making transverse incisions in the bark. This gum is in constant use by Turkish and Arab women in the harems under the impression that it whitens the teeth and perfumes the breath. Oil is pressed from the seeds, one hundred kilos producing twenty litres of oil. It is used by the Arabs for food and lights. The flexible twigs are used by the same people for baskets.

mexicana, HBK. A small shrub or tree: lvs. odd-pinnate on a somewhat winged or angled slightly hairy petiole; lfts. 9-12 pairs, ovate or cuneate, obtuse, glabrous, $\frac{1}{2}$ in. long, oblique at the base; fls. in axillary panicle spikes fr. $1\frac{1}{4}$ -2 lines diam., smooth and somewhat compressed. Mex. and Calif.—A very ornamental shrub or small tree, sparingly in cult.

mûta, Fisch. & Mey. Tree up to 35 ft. high: the bark dark brown with longitudinal fissures; lvs. deciduous, odd-pinnate; lfts. 2-4 pairs, oblong or oblong-ovate, obtuse; the petioles marginate or slightly winged, puberulent; drupe $1\frac{1}{4}$ in. long, obovate, flattened, obliquely apiculate. Asia Minor.—The heartwood is dark brown and very hard. Some cultivators dislike it as a stock for *P. vera*, finding difficulty in making the grafts take.

vera, Linn. **PISTACHIO**. Small tree up to 30 ft. high, with spreading branches; lvs. pinnate, at first tomentose, then glabrous, somewhat coriaceous, borne on angular petioles; lfts. 1-5 pairs, ovate, obtuse, nearly sessile (in one variety in cult. in Calif. the lvs. have only 3-5 lfts.): drupe ovoid, oblong, pedicelled, reddish and wrinkled. Medit. region and Orient.—The kernel has a rich, oily, agreeable flavor and in different varieties is either pale green or creamy yellow.

F. TRACY HUBBARD.

PÍSTIA (probably from Greek, *pistos*, watery; referring to its aquatic nature). *Araceæ*. **WATER-LETTUCE**. **TROPICAL DUCKWEED**. A small tender, perennial floating herb desirable for aquaria.

Flowers unisexual; spadix without appendage, adnate to the back of the spathe; male fls. in whorls, with 2 very short stamens which are much grown together and inserted at the apex of the spadix; female fls. solitary; ovary 1-celled; ovules numerous, orthotropous, in 4-6 series; fr. baccate, irregularly breaking open, normally with many seeds. Botanically, the genus *Pistia* is unique. The monographer of the aroids (Engler, in DC. Monogr. Phaner. 2, 1879) makes *Pistia* the sole representative of a subfamily, one of his 10 primary natural divisions of the arum family. He regards the pistias as all one species, though 9 or more have been described. He recognizes 4 well-marked varieties, based upon the shape of the lvs., which he calls *cuneata*, *spatulata*, *obcordata* and *linguiformis*. After the continental fashion Engler takes no one of these as a type to which the others are referred. It is probable that the form with obcordate lvs. is the one chiefly cult. in American water-gardens. It forms a loose rosette of lvs. and has long slender feathery roots. The plant sends out runners on which may sometimes be seen young plants in all stages of development. A healthy plant measures about 6 in. across. The lvs. are generally more or less wedge-shaped, 2-5 in. long, pea-green, velvety to the touch, and covered beneath with a sort of mealy down. The pistia rosette has been compared to a half-grown lettuce plant before the head has formed. Like many other aquatics, the water-lettuce has an immense range. It is found in fresh waters throughout the tropics, and in the U. S. is native from Fla. to Texas.

Water-lettuce is commonly grown outdoors in summer in collections of tender aquatics, and also in aquaria. The summer temperature of the water should be 70° to 80° F. Although it grows well when floating free in several feet of water, it seems to do better when

placed in shallow water where the roots may reach the soil. Larger-sized plants may be secured by using a thin layer of rich soil or well-rotted manure in the bottom of the vessel. Soft water is said to be essential. Running water is not necessary. The plants should be shaded during the middle of the day in summer, or the foliage is likely to become yellow and sickly-looking.

Stratiotes, Linn. **WATER-LETTUCE**. **TROPICAL DUCKWEED**. Tender perennial aquatic herb already described. The small white fls., though inconspicuous and borne at the bottom of the cup of lvs., are large enough to show at a glance their relation to the arum family. B.M. 4564. F.S. 6:625. J.F. 2:137. Var. *spatulata*, Engler. Lvs. spatulate, velvety green, more deeply nerved than the type. S.E. U. S., Trop. Amer.

WILHELM MILLER.

PISUM (Greek and Latin name of pea). *Leguminosæ*. Mostly tendril-climbing herbs of the Medit. region and eastward, one of which is the common pea.

Hardy annuals or perennials of easy culture, growing well in the cooler months; calyx-tube oblique at the base, the lobes more or less leafy; standard obovate or

2987. *Pisum sativum*. ($\times \frac{1}{2}$)

orbicular; wings adhering to the keel; style mostly rigid, widened above, bearded down the inner margin; lfts. 1-3 pairs, the lf. ending in a tendril or point, the stipules conspicuous.—Species about a half dozen.

sativum, Linn.

GARDEN PEA. Fig. 2987. Annual, glabrous and glaucous, tendril-climbing: stipules large and leafy (usually as large as lfts.): lfts. oval or ovate, 2-3 pairs, the lf. ending in tendrils; fls. few,

on an axillary peduncle, white; seeds globular. Eu., Asia.—The pea runs into many forms, which have been variously named. Two major types of garden peas are those grown for the seeds (shelling peas) and those grown for the edible pods (sugar peas). See *Pea*.

Var. **arvense**, Poir. (*P. arvense*, Linn.). **FIELD PEA**. Fls. usually bluish, light lilac, or dull white, with purple wings, and greenish keel, 1-3 on peduncle about as long or little longer than stipules; seeds angular, often gray. Grown for forage.

Var. **saccharatum**, Hort. **SUGAR PEA**. Fls. mostly in 2's; pod large and soft, more or less fleshy, sweet, not dehiscing, edible.

L. H. B.

PITANGA: *Eugenia uniflora*.

PITCAIRNIA (W. Pitcairn, a London physician). *Bromeliaceæ*. Billbergia-like very short-stemmed perennial herbs or subshrubs.

Leaves in dense rosettes, narrow, often prickly-margined; infl. a central spike or raceme of long-tubular red, yellow or nearly white fls.; fls. perfect; sepals 3, free; petals 3, unguiculate, erect or spreading at the apex, usually with 2 small scales at the base; stamens 6, free, with linear anthers; fr. a 3-valved caps., with numerous seeds.—Mez, the recent monographer of the bromeliads (in DC. Monogr. Phaner. 9), admits 134 species of Pitcairnia. See also Baker in Journ. Bot.

1881. They are American, mostly tropical. In choice collections, various species of pitcairnia may be expected, but very few of them are in the American trade. For pictures of two Mexican species, *P. Jaliscana* and *P. Palmeri* (not cult.), see G.F. 1:197 and 211. *P. farinosa* is an undetermined trade name. For other species, see *Puya*. For cult. of pitcairnia, follow advice given under *Billbergia*.

A. Infl. on a scape.

B. Fls. pendulous.

corállina, Lind. & André. Stemless: outer lvs. hard and dry, without marginal spines, the inner ones with brown-spined petioles and broad plicate recurved blades which are somewhat scurfy on the back: peduncle about 1 ft. long, bright red, the raceme of about equal length and drooping: fls. coral-red, about 3 in. long, the calyx part comprising about one-third of this length; stamens as long as the petals, with white filaments; stigmas twisted. Colombia. R.H. 1875:250. B.M. 6600.—Perhaps the best species.

BB. Fls. erect.

Moritziana, Koch (*P. Klotzschiana*, Baker). Stemless: lvs. linear, in a rosette, 12–18 in. long, usually spineless and the petiole short or none: raceme 1 ft. or less long, on a leafy peduncle of about the same length; fls. red or yellowish, usually not 3 in. long. Venezuela. R.H. 1903, p. 175.

AA. Infl. sessile.

heterophylla, Beer (*P. Morrénii*, Lem. *Puya heterophylla*, Lindl.). Stemless: lvs. of two kinds, the outer ones narrow and spiny, brown, and being the termination of bulb-like scales, the later ones being longer (16–24 in.) and green and entire: fls. rose or white, in a close oblong spike that is shorter than the green lvs., the latter arising, however, from separate shoots. Mex. to Venezuela and Ecuador. B.R. 26:71. J.F. 3:291.—Odd.

Var. **exscapa**, Mez (*P. exscapa*, Hook.). Differs in its intense purple-red fls. Ecuador. B.M. 4591. J.F. 2:151.

P. alpestris=*Puya*.—*P. cærúlea*=*Puya*.—*P. echinata*, Hook. Lvs. of two kinds, the one scale-like, the other normally developed, up to 3 ft. long and 2½ in. wide, spiny: panicle bipinnate; sepals acute, keeled, echinate with stellate hairs; petals yellow. Colombia. B.M. 4709. J.F. 4:407.—*P. flammæa*, Lindl. Lvs. up to 3 ft., and 1½ in. broad, linear-ensiform, entire: racemes densely many-fl., on a scape; sepals acute; petals red. Brazil. B.M. 7175 (as *P. Roezlii*).—*P. Funckiana*, A. Dietr. Lvs. 1–2 ft. long, 2 in. wide lanceolate, glabrous, unarmed: fls. in a lax raceme on a manifest scape; sepals obtuse; petals white. Guiana and Colombia. Gt. 4:44. B.M. 4705 (as *P. macrocalyx*).—*P. Jacksonii*, Hook.=*P. punicea*.—*P. Karwinskyana*, Schult. Lvs. of two kinds, the one persistent, setiform, the other normal, deciduous when old, up to 1 ft. long, and ½ in. broad, unarmed, glabrous, grass-like: raceme few-fl., on a manifest scape; sepals acute; petals red. Mex.—*P. Micheliæna*, André. Tufted, stemless: lvs. linear, channeled, 2 ft. or more long: scapes tall, bearing spikes of scarlet-red fls. Mex. R.H. 1901:576.—*P. punicea*, Scheidw. Lvs. up to 10 in. long, less than ½ in. wide, narrowly linear-lanceolate, longly acute, glabrous above, pale scaly beneath: raceme on a scape, several-fl.; sepals obliquely acute, scaly; petals brick-red. Mex. J.F. 2:127. B.M. 4540 (as *P. Jacksoni*).—*P. recurvata*, Koch. Lvs. 2 ft. long, 1–2 in. broad, lanceolate, minutely serrulated toward the tip: fls. in dense raceme, 4–6 in. long, milk-white. Brazil.—*P. ringens*, Klotzsch & Link. Lvs. of two kinds, the one brown, awl-shaped, the other grass-like, 2½ ft. long, about ½ in. broad, unarmed except at base, glabrous: raceme few- to several-fl., on a manifest scape; sepals acute; petals red. Mex. Gt. 2:53.—*P. spathacea*, Griseb.=*Puya spathacea*, Mez.—*P. suarezensis*, Lindl. Lvs. up to 18 in. long, and about ½ in. broad, narrowly ensiform, unarmed, green: raceme dense, on a manifest scape; sepals very acute; petals yellow. Brazil. B.R. 1069.—*P. tabulariformis*, Lind. Lvs. up to 6 in. long, 1½ in. wide, oblong-spatulate: infl. globose, head-like, sessile: sepals acute; petals red. I.H. 9:344. F.M. 5:297. B.M. 8410.—*P. undulata*, Scheidw. Outer lvs. triangular, brown, entire, the inner ones few, up to 2 ft. long, ¾ in. wide, unarmed, undulate, pale scaly on back: raceme many-fl., on a manifest scape; sepals acute, scaly, becoming glabrous; petals red. S. Brazil. F.S. 2:162 (as *P. Altensteini*). Gt. 781.

GEORGE V. NASH.†

PITCHER PLANTS are various carnivorous plants bearing pitchers which in some cases contain a secreted liquid by the aid of which the plant digests the bodies of insects. The native pitcher plants of the

northern and southern states are *Sarracenias*. The California pitcher plant is described under *Darlingtonia*. The favorite pitcher plants of greenhouses are *Nepenthes*. All these plants have a morphological resemblance in their pitcher-bearing foliage, but their flowers and seeds are so apparently unlike that they suggest derivation from widely different parts of the vegetable kingdom. The genus *Nepenthes* might possibly be derived from the *Aristolochia* family, being a derivative along one line, while the parasitic *Cytinaceæ* might be regarded as having degenerated along another line from the same source. The Australian genus *Cephalotus*, which has a pitcher strikingly like the pitchers of *Nepenthes*, may be an outlying relative of the saxifrage family. *Sarracenia*, *Darlingtonia*, and the Venezuelan genus *Heliamphora* seem to be more closely allied to one another than to the others, and they make up the *Sarraceniacæ*. See the different generic entries for fuller accounts.

PITHECOCTENIUM (Greek, *monkey's comb*; alluding to the spiny fruit). *Bignoniaceæ*. Ornamental vines cultivated for their showy flowers.

Evergreen shrubs climbing by lf-tendrils: young branches ribbed: lvs. opposite, 3-foliolate or the middle lf. replaced by a filiform 3-parted tendril: fls. in terminal racemes or panicles; calyx campanulate, truncate or with small teeth; corolla campanulate, tubular at the base, curved, leathery, white or yellowish; stamens included; disk large; ovary warty, with many seeds in several rows: caps. broad, densely covered with prickly warts; the persistent septum with enlarged margin.—About 20 species in Cent. and S. Amer. From the allied genera *Bignonia* and *Anemopaegma* it is easily distinguished by the prickly caps. and the ovary with the seeds in several rows. Adapted for cult. in subtropical and tropical countries only. For cult. and prop. see *Bignonia*.

cynanchoides, DC. (*P. clematideum*, Griseb. *Anemopaegma clematideum*, Griseb. *Bignonia alba*, Hort., not Auth.). Branchlets slightly hairy at first: lfts. ovate, long-acuminate and obtusely pointed, subcordate or broadly cuneate at the base, glabrous above, 1–2 in. long; petiole pubescent at the apex: fls. in terminal few-fl. racemes; the lowest pair of fls. long-stalked; corolla white, tubular-funnelform with spreading limb, pubescent outside, 1¾–2 in. long; ovary tomentose: fr. 2½ in. long, covered with yellowish spines. Nearly all the year. Argentina, Uruguay. Hieronymus, Leon. Descr. Plant. Argentina, 7. B.M. 8556.

muricatum, DC. (*Bignonia echinata*, Jacq.). Glabrous: lfts. ovate, acute or acuminate, rounded or subcordate at the base: fls. in terminal many-fl. racemes; corolla about 1 in. long, white, with yellow throat: fr. oblong, 2–5 in. long, densely covered with prickles. Mex.

P. buccinatum, Mairet=Phædranthus buccinatorius.—*P. cinereum*, DC.=Distictis cinerea.

ALFRED REHDER.

PITHECOLÒBIUM (Greek, *monkey*, and *ear-ring*). *Leguminosæ*. Tropical shrubs or trees planted for ornament and shade.

With or without axillary stipular spines: lvs. bipinnate; lfts. at first small, many pinnate or large, 1–3-pinnate, rarely with 1 lf.; petiolar glands rarely wanting; stipules small and inconspicuous or persistent, hardened or spiny: fls. 5- or rarely 6-merous, hermaphrodite or rarely polygamous, in head-like spikes; calyx campanulate or tubular, short-toothed; corolla tubular or funnelform; stamens few or many, much exerted, at the base or above united into a tube; anthers small; ovary sessile or stipitate, many-ovuled, style filiform, stigma terminal, small or capitate; pod compressed or flattened, circinate, twisted falcate, or rarely nearly straight, coriaceous, thick or somewhat fleshy, 2-valved, not septate between the seeds; seed

pulpy, short, often dark-colored, ovate or orbicular, compressed; funiculus filiform or with variously expanded fleshy arils.—About 125 species. The subgenus *Samanea* of Benth. is of generic rank. See *Samanea*, Vol. VI. It is distinguished from *Pithecolobium* by its straight indehiscent septate pods, and from *Enteolobium* by its straight, more or less constricted instead of short thick circinate or reniform pods.

INDEX.

angulatum, 6.	latifolium, 11.	Sonoræ, 10.
brevifolium, 9.	lobatum, 4.	texense, 8.
dulce, 1.	mexicanum, 7.	tortum, 12.
flexicaule, 8.	pruinosum, 5.	Unguis-cati, 3.
guadalupense, 2.	scutiferum, 4.	

A. *Stipules mostly spiny: lvs. 1- or rarely irregularly 2-pinnate; lfts. 1- or few-pinnate: pod spirally twisted; seed with funiculus dilated at apex into a fleshy aril. (Unguis-cati.)*

B. Heads with short peduncles.

1. *dulce*, Benth. (*Mimosa dulcis*, Roxbg. *Ingá dulcis*, Willd.). GUAYMOCHIL, HUAMUCHIL, or MANILLA TAMARIND. Large stately trees: lvs. and lfts. 1-pinnate; lfts. obovate or oblong, obtuse, very oblique, about 1 in. long: heads short-peduncled, the upper paniculate-racemose; fls. white, finely pubescent; calyx 1 line, corolla $1\frac{1}{2}$ lines long, white: pod twisted, 5-6 in. long, $\frac{1}{8}$ - $\frac{1}{2}$ in. broad. Mex., Philippines. Blanco Fl. Filip. 237. Beddome, Fl. Sylv. 188.—Widely cult. in the tropics as an ornamental. The pulpy aril of the seed is eaten by the poorer classes as food. The bark yields a yellow dye. It is said not to have fruited in S. Calif.

BB. Heads with long slender peduncles.

c. Lfts. leathery: ovary pubescent.

2. *guadalupense*, Chapm. (*Ingá guadalupensis*, Desv.). An unarmed shrub, 3-7 ft. high: lfts. 4, obliquely obovate, $\frac{3}{4}$ - $1\frac{1}{2}$ in. long, leathery, mucronate, undulate, delicately nerved, shining above; petioles shorter than the petiolules: heads yellow; peduncles solitary on the axils, $1\frac{1}{2}$ -3 in. long, exceeding the subtending bracts; calyx campanulate, pubescent, triangular lobes shorter than the tube; corolla pubescent, stamens 3-4 times longer than the corolla: pods 2-4 in. long, contorted. Fla. and W. Indies.

cc. Lfts. membranous: ovary glabrous.

3. *Unguis-cati*, Benth. (*Mimosa Unguis-cati*, Linn.). CATS-CLAW. BLACK BEAD. BREAD-AND-CHEESES. UNA DE GATO. An armed or unarmed shrub or small tree, sometimes 25 ft. high: lfts. 4, rather thin, obliquely obovate, oval, rounded or mucronate at the apex, finely reticulated; petioles slender, mostly larger than the petiolules: heads in terminal axillary panicles; calyx turbinate-campanulate, glabrous; corolla glabrous or nearly so; stamens twice as long as the corolla: pods 3-4½ in. long, contorted. Fla., W. Indies, and Trop. Amer. Jacq. Hort. Schoenbr. 3:392. Vahl, Eclog. 3:25.—The bark is astringent, fr. edible, and the seeds medicinal.

AA. *Stipules inconspicuous: spineless: lvs. 1- to several-pinnate; lfts. 1- to several-pinnate, large or many-pinnate and small: heads small, paniculate: pod spirally twisted; seed without apex of funiculus dilated. (Clypearia.)*

B. Fls. mostly few, sessile, in heads.

4. *scutiferum*, Benth. (*Mimosa scutifera*, Blanco. *P. lobatum*, Benth.). A small tree: lvs. glabrous, 1-2-pinnate; lfts. 2-3-pinnate, ovate or oblong, acuminate, 3-6 in. long: fls. in heads, few (often 2-3) sessile, glabrous, or puberulent; calyx $\frac{1}{2}$ -1 line long; corolla up to 2 lines long: pod twice or irregularly twisted, often nearly a foot long, 1-2 in. diam., often much constricted between seeds; seeds large, compressed, orbicular. Trop. Asia, Java, Borneo, Philippines.

BB. Fls. many, in heads, distinctly pedicelled.

c. Branches terete: lvs. large, few-pinnate.

5. *pruinodum*, Benth. (*Albizzia pruinosa*, F. Muell.). A slender tree, brownish puberulent or glabrous: lvs. 1-2-pinnate; upper lfts. 3-4-pinnate, broadly ovate or subrhombic, largest acuminate, 2-3 in. long: fls. in heads in the upper axils or in short corymbose terminal panicles, pedicellate, glabrous; calyx $\frac{1}{2}$ line long; corolla 2 lines long: pod spirally twisted or long-contorted, glabrous, deeply constricted, about $\frac{5}{8}$ in. broad. E. Austral.—Intro. in 1901.

cc. Branches angular: lvs. several- to many-pinnate.

6. *angulatum*, Benth. (*Ingá angulata*, Graham. *Mimosa heterophylla*, Roxbg.). An ornamental small tree: branches and petioles at first brownish, puberulent, becoming glabrous: lvs. 2-4-pinnate; upper lfts. 4-8-pinnate, oblique, ovate-oblong, acuminate, 3-5 in. long, lower shorter, ovate-rhombic: panicle terminal; fls. few, in heads, pedicellate, tomentulose; calyx less than a line long; corolla about 3 lines long: pod circular or elongated, contorted, about $\frac{1}{2}$ - $\frac{5}{8}$ in. broad. Trop. Asia, Borneo, Philippines.

AAA. *Stipules present: shrubs (or rarely trees): lvs. 1- to several-pinnate; lfts. small or rarely 1 in. long. (Ortholobium.)*

B. Spines straight.

c. Lvs. 2-6-pinnate.

D. Lfts. 5-10-pinnate.

7. *mexicanum*, Rose. CHINO. A small tree, 15-20 ft. high, 1 ft. diam.: lvs. with straight stipular spines (sometimes wanting) 1 line long, 2-5-pinnate; lfts. 5-10-pinnate, oblong, 2-4 lines long, midrib a little excentric, puberulent, as are also the rachis and branches: infl. paniculate; fls. in heads, pedicellate; pedicels 1-2 lines long; calyx $\frac{1}{2}$ line long; corolla $1\frac{1}{2}$ lines long; petals spreading or reflexed; stamens long, numerous: pods oblong, somewhat constricted, 3-4 in. long, 1 in. broad, straight, its valves not elastic nor revolute; seeds 2, oval, 2-4 lines long. Mex.—It has the habit of mesquit and is valued for its wood. Rare, and rapidly becoming exterminated.

DD. Lfts. 3-6-pinnate.

8. *flexicaule*, Coult. (*P. texense*, Coult. *Acacia flexicaulis*, Benth.). EBONY. A shrub or small tree, 20-30 ft. high: trunk 2-3 ft. diam., branching 8-10 ft. from ground, with short stout stipular spines: lvs. 4-6-pinnate, long-petiolate; petioles slender, puberulent; lfts. 3-6-pinnate, lower pair shortest, ovate-oblong, rounded at apex, glabrous, membranaceous or subcoriaceous, dark green, shining on the upper surface, paler below, $\frac{1}{4}$ - $\frac{1}{2}$ in. long on short broad petiolules: fls. in cylindrical dense or interrupted spikes, $1\frac{1}{2}$ in. long on stout pubescent peduncles, fascicled in axils of lvs. of preceding year, sessile, yellow or creamy, fragrant; stamens exserted; corolla 4-5 times longer than calyx, puberulent; ovary glabrous, sessile: pod flattened, turgid, straight or falcate, sessile, oblique at base, rounded and narrowed to a short point at apex, 4-6 in. long, 1-1½ in. broad, dehiscent, thick, woody; seed imbedded in a thick pitchy pulp, suspended on a short straight funiculus, $\frac{1}{2}$ in. long, $\frac{1}{4}$ in. broad, irregularly obovate, bright reddish brown, sides faintly depressed. Texas to Low. Calif. S.S. 3:147.—The wood is heavy, hard, compact, close-grained, dark rich reddish brown tinged with purple, with clear bright yellow sapwood. Almost indestructible in contact with the ground and much used for fence-posts. The seeds are palatable and nutritious if boiled when green. They are roasted when ripe by the Mexicans who use the thick seed-coat as a substitute for coffee. A slow grower and not of sufficient size for timber.

cc. *Lvs.* 6-10-pinnate; *lfts.* 20-40-pinnate.

9. *brevifolium*, Benth. (*Acacia Neuciandra*, Buckl.). HUJILLO. An evergreen shrub or small tree up to 30 ft. tall, armed with short spines: *lvs.* 6-10-pinnate; *lfts.* 20-40-pinnate, oblong or narrowly oblong, $\frac{1}{8}$ - $\frac{1}{4}$ in. long, obtuse or acutish, reticulated beneath; panicles 2-4 in. long, peduncles $\frac{3}{8}$ - $\frac{1}{2}$ in. long; heads subglobose, $\frac{5}{8}$ - $\frac{3}{4}$ in. diam.; corolla 6-8 times longer than the calyx, lobes ovate, shorter than the tubes; stamens 2-3 times longer than the corolla; pods linear, oblong, flat, $2\frac{1}{2}$ -4 in. long, acuminate at apex, stipitate. Texas and Mex. S.S. 3:146.—The fls. are whitish and much sought by bees.

BB. *Spines recurved.*

10. *Sondrae*, Wats. UNA DE GATO. A shrub or small tree 15-20 ft. high, armed with short recurved stipular spines: foliage, infl. and branches canescent with very short spreading pubescence: *lvs.* 1-pinnate on a short (1-2-line) or very short rachis; *lfts.* 10-15-pinnate, oblong-elliptic, about a line long; peduncles mostly solitary (1-3) in the axils, 6 lines long or less; heads loose; fls. white, finely pubescent, nearly 2 lines long; pod rather thin, short-stipitate, flat, straight, dehiscent, puberulent, 2-4 in. long and $\frac{1}{2}$ - $\frac{3}{4}$ in. wide, 3-6-seeded. Mex.—Wood very hard and takes a fine polish. A good hedge plant for the Southwest if trimmed. A decoction of the branches is used for scours in horses.

AAAA. *Stipular spines absent: lvs. 1- or rarely 2- or more-pinnate; lfts. 1- to several-pinnate, large: fls. usually short, in heads or spikes at nodes of leafless branches: pod stiff, leathery.* (*Caulanthos*.)

11. *latifolium*, Benth. (*Mimosa latifolia*, Linn. *Inga latifolia*, Willd. *Calliandra latifolia*, Griseb.). A small tree or tall shrub, entirely glabrous: stipules persistent, lanceolate-acuminate: *lvs.* 1-pinnate; *lfts.* often 2-pinnate, ovate or ovate-oblong, acuminate, 3-6 in. long; fls. in loose nearly sessile or short-peduncled heads; calyx very small; corolla about $\frac{1}{4}$ in. long; pod curved, often a foot long and an inch broad. Brazil to Panama and in the W. Indies. Mart. Fl. Bras. 15, 2:119.

AAAAA. *Stipules fascicled: lvs. 2- to several-pinnate; lfts. 5- to many-pinnate, small: infl. in heads, axillary, peduncled; fls. sessile, short, glabrous: pod smooth, leathery or somewhat fleshy, straight or curved, scarcely dehiscent.* (*Chloroleucon*.)

12. *tortum*, Mart. A shrub or small tree, glabrous or pubescent: *lvs.* 2-5-pinnate; *lfts.* 5-9-pinnate, oblique, oblong, $\frac{1}{4}$ - $\frac{1}{2}$ in. long; calyx less than a line long; corolla about $\frac{1}{4}$ in. long; pod curved or almost circular, about 6 in. long, $\frac{1}{2}$ - $\frac{2}{3}$ in. broad. Brazil. Mart. Fl. Bras. 15, 2:118.

P. acle, Vidal (*Mimosa acle*, Blanco)=*Albizia acle*, Merrill.—*P. albicans*, Benth. (*Acacia albicans*, Kunth). Canescent-puberulent: *lvs.* 4-6-pinnate; *lfts.* 12-20-pinnate, oblique, linear-oblong, 3-4 in. long; infl. axillary; fls. glabrous; calyx $\frac{1}{2}$ line long; corolla 2 lines long; pod glabrous, 3-5 in. long, $\frac{1}{2}$ in. broad, coriaceous. Mex.—*P. filicifolium*, Benth. (*Mimosa filicifolia*, Lam.)=*Samanea filicifolia*, Ricker.—*P. fragrans*, Benth. (*Inga fragrans*, Macfad. *Acacia Berteriana*, DC.). Scabrous or minutely pubescent: *lvs.* 8-10-pinnate; *lfts.* 30-40-pinnate, oblong-linear or linear-falcate, 2-4 in. long, dark above, pale beneath, costa excentric; heads pedicellate in racemose panicles; calyx $\frac{1}{2}$ - $\frac{3}{4}$ line long; corolla $1\frac{1}{2}$ -2 lines long; pod straight, smooth, not much thickened, 3-4 in. long, 6 lines broad, indehiscent. W. Indies.—*P. geminatum*, Benth. (*Calliandra? geminata*, Benth.)=*Inga geminata*, Wight & Arn. An ornamental tree with large fls. Ceylon. Hook. Ic. 16:1510.—*P. Saman*, Benth. (*Mimosa Saman*, Jacq. *Enterolobium Saman*, Prain)=*Samanea Saman*, Merrill.—*P. umbellatum*, Benth. (*Mimosa umbellata*, Vahl. *Acacia Concordiana*, Loud.). Puberulent: *lvs.* 1-2-pinnate; *lfts.* 4-10-pinnate, oblique-oblong, obtuse, $\frac{1}{2}$ - $\frac{3}{4}$ in. long; fls. in pedicellate heads, glabrous; calyx 1-1 $\frac{1}{2}$ lines long; corolla 3-3 $\frac{1}{2}$ lines long; pod curved, thick, 3-4 in. long, $\frac{3}{4}$ in. broad, constricted between the seeds. India.

P. L. RICKER.

PITTIOSPORUM (Greek, *pitch seed*; in allusion to the resinous coating of the seeds). *Pittosporaceæ*. Hardy or half-hardy evergreen woody plants grown especially in California and Florida. Several species are

excellent hedge plants, much preferred to privet and box in some localities; many are useful ornamentals for lawns and shrubberies; a few are used as avenue trees; nearly all have fragrant flowers.

Shrubs and trees: *lvs.* simple, exstipulate, alternate or apparently whorled: fls. regular, the parts in 5's; sepals distinct or connate at base; petals distinct or lightly united, tips often recurved; ovary incompletely 2-celled (rarely 3-5-celled); style 1; stigma 1; fr. a globose, ovate or obovate caps., 2- to many-seeded; valves leathery or woody.—About 100 species, chiefly of the southern hemisphere and largely Australian.

Pittosporums are usually propagated by seeds, which are sown in winter or early spring in ordinary soil in the cool greenhouse. Seeds do not keep well and those of the rarer kinds are difficult to procure; but all species are readily propagated from cuttings of half-ripened wood. *P. Tobira*, which seldom sets seeds, and its variety, which does not come true, are also obtained in this manner. *P. phylliræoides* is best if grafted upon *P. undulatum*, since otherwise it is liable to be crooked and branched. *P. eriocarpum* is also grafted upon this stock. Seedlings should be reported from the seed-bed as soon as the second or third leaf has formed.

2988. *Pittosporum Tobira* var. *variegatum*. ($\times \frac{1}{2}$)

A. *Fls. chocolate to black: seeds black.*

1. *crassifolium*, Soland. KARO. Tall shrub or small tree, 15-30 ft.: young parts densely clothed with white or buff downy pubescence: *lvs.* 2-3 in. long, narrow-obovate or oblong, obtuse, narrowed to a short petiole, very leathery, dark green above, downy beneath, the margins revolute: fls. $\frac{1}{2}$ in. long, in terminal clusters: fr. $\frac{3}{4}$ -1 $\frac{1}{4}$ in. long, short-hairy, with 3 or 4 thick woody valves; seeds ripen in about five months. New Zeal. G.C. III. 30:431. Kirk, For. Fl. N. Z. 14. F.S. 21:2151. B.M. 5978.—Suitable for windbreaks and shelter near the sea; said to resist gales and salt spray; too coarse and rigid for ordinary yard planting. Wood white and tough; used for inlaid work; difficult of combustion.

2. *tenuifolium*, Gaertn. (*P. nigricans*, Hort.). TAW-HIWHI. Shrub or small tree, 20-40 ft., of symmetrical and compact growth: *lvs.* 1-3 in. long, oblong or somewhat obovate, mostly acute, thin, dark green, glabrous and lustrous when mature, the margins undulate: fls. $\frac{1}{4}$ - $\frac{1}{2}$ in. long, solitary in the lf.-axils, rarely fascicled; ovary silky: fr. $\frac{1}{2}$ in. thick, globose,

3-valved, glabrous and minutely roughened when mature. New Zeal. Kirk, For. Fl. N. Z. 46.—One of the best for clipped hedges, for mass planting, and for screening off undesirable views. Occasional pruning is necessary if a dense foliage is desired. Both this and No. 1 have yellow-fl. forms but these are not in the trade.

AA. Fls. white, greenish, or yellow.

B. Lvs. very obtuse, thick and leathery, but less so in *P. erioloma*.

3. *Tobira*, Ait. TOBIRA. JAPANESE PITTOSPORUM. Winter-flowering shrub, 6–10 ft.: lvs. 2–3½ in. long, 1–1½ in. wide, obovate, very obtuse, narrowed to the short petiole, thick and leathery, perfectly glabrous, margins revolute: fls. white or yellowish, fragrant, ¾ in. long, in terminal umbels: fr. ½ in. long, ovoid, angled, densely short-hairy. China and Japan. B.M. 1396. Var. *variegatum*, Hort. (Fig. 2988), has lvs. (often thinner) variegated with white.—In the E. this variety is the favorite pittosporum, as it makes a good house plant: both forms are cult. in Fla. and Calif. as lawn plants and for shrubberies: the deep green foliage and fragrant fls., the latter resembling orange blossoms, are very agreeable. Withstands violent saline winds better than most other shrubs, according to Franceschi.

4. *erioloma*, Moore & Muell. Tall shrub, 10–12 ft. or more, branching close to ground: lvs. 2–3 in. long, ½–1 in. wide, oblanceolate to obovate, obtuse, short-petioled, leathery but not so thick as in *P. Tobira*, deep green, paler beneath, glabrous at maturity, margins revolute: fls. yellowish, few in terminal umbels, ½ in. long, equaling the pubescent pedicels; sepals 1½ in. long, pubescent within: fr. globose, glabrous, ½–¾ in. across. Lord Howe's Isl.—Resembles *P. Tobira* and *P. viridiflorum* but is more desirable as an ornamental in that it is densely leafy to the ground and has handsome foliage.

5. *viridiflorum*, Sims (*P. sinense*, Desf.). CAPE PITTOSPORUM. Characters much as in *P. Tobira*, but becoming larger, to 25 ft., more tree-like: fls. smaller, greenish and yellow, in dense compound clusters: fr. subglobose, glabrous. Dec.–April. S. Afr. B.M. 1684.—One of the best of the larger pittosporums, scarcely known as yet; intro. by Franceschi.

BB. Lvs. acute, thin.

c. The fls. in terminal clusters: lvs. lanceolate or broader.

D. Young lvs. glabrous or nearly so.

E. Petals about ½ in. long.

6. *undulatum*, Vent. VICTORIAN BOX. MOCK ORANGE. Fig. 2989. Tree, to 40 ft. or more, but often pruned as a shrub: lvs. crowded on the branchlets, 3–5 in. long, 1–2 in. broad, oval-oblong to lanceolate, abruptly acute, deep green, coriaceous and shining, entire, undulate or flat: fls. white; sepals more than half as long as corolla, acuminate: fr. scarcely ½ in. long, nearly globose, smooth; seeds numerous, light brown. Jan.–July. Austral. B.R. 16.—Suitable for large broad hedges with dense foliage; when well spaced makes a large tree: used as an avenue tree in S. Calif., where it attains stately dimensions. Often selected for planting near summer-houses and dining-porches because of the rich odor of the bloom, resembling that of orange blossoms.

EE. Petals less than ¼ in. long.

7. *eugenioides*, A. Cunn. TARATA. Tall shrub or slender open tree with sparse and glossy light green foliage: lvs. 2–4 in. long, ¾–1¼ in. wide, elliptic-oblong, acute, undulate: fls. greenish yellow, numerous; sepals minute, acuminate: fr. slightly exceeding ¼ in. long, ovoid, pointed at each end, ribbed, glabrous when mature. New Zeal. Kirk, For. Fl. N. Z. 49.—In Calif. the most extensively cult. species, much used for clipped hedges and ornamental shrubbery; hardy;

growth rapid; grows in pure limestone shale (Braunton); a variegated variety is cult. in Eu. Gn. 77, p. 277.

8. *rhombifolium*, A. Cunn. QUEENSLAND PITTOSPORUM. Pyramidal tree, to 80 ft.: lvs. 3–4 in. long, 1–2 in. wide, rhomboid, acuminate, coarsely toothed: fls. white, numerous, in terminal corymbs: fr. berry-like, ¼ in. long, nearly globose, becoming bright orange-yellow, glabrous; seeds 2–3, black. June–Sept. Austral. Hook. Icon. 621.—Sometimes grown as a pot-plant, more often as a tree for lawns and avenues. The bright berries persist through autumn and winter, making the tree very attractive.

DD. Young lvs. very pubescent, as also the fr.

9. *revolutum*, Ait. Tall shrub, rusty-pubescent on young parts: lvs. 2–3 in. long, 1–1½ in. wide, elliptic, glabrous above when mature, rusty-pubescent beneath, entire or undulate: fls. pale yellow, fully ½ in. long; sepals acuminate: fr. ½–¾ in. long; seeds numerous, red or brown. Feb.–April. Austral. B.R. 186.

10. *eriocarpum*, Royle. Widely spreading shrub or tree, 10–20 ft., the young parts white-tomentose: lvs.

2989. *Pittosporum undulatum*. (× ½)

4–6 in. long, 1½–2½ in. wide, elliptic or oblong, narrowed to the ends, white-tomentose beneath: fls. yellow, ½ in. long, numerous in an oblong terminal raceme, fragrant: fr. ¾ in. long. Himalayas. B.M. 7473.—Grown in S. Calif.: very useful when a mass of light-colored foliage is desired: fls. notably banana-scented.

CC. The fls. axillary: lvs. linear.

11. *phillyræoides*, DC. NARROW-LEAVED PITTOSPORUM. Glabrous tree, to 20 ft. or more, with pendent twigs: lvs. 2–3½ in. long, about ¼ in. wide, entire; tips slender, recurved: fls. yellow, under ½ in. long, pedicelled in the lf.-axils: fr. about ½ in. long, oval, compressed, yellow, granular. Australian deserts. Maiden, For. Fl. N. S. W. 4.—Remarkable tree, resembling weeping willow but evergreen and suited to dry regions: root-suckers abundant.

P. bicolor, Hook. f. Shrub or tree with tomentose twigs: lvs. linear, glabrous above, tomentose beneath: fls. axillary, ½ in. long, yellow and purple. Austral.—*P. Buchanani*, Hook. f. Closely allied to *P. tenuifolium*: lvs. 2–5 in. long, oblong-lanceolate, acute, very thin, flat: fr. less than ½ in. thick. New Zeal.—*P. Colsenii*, Hook. f. Sometimes considered as a form of *P. tenuifolium*: branches stouter: lvs. 2–4 in. long, sharply pointed, flat, more coriaceous and deeper green. B.M. 3305. G.C. III. 26:370. Cult. in England.—*P. Fairchildii*, Cheesem. Shrub, related to *P. crassifolium*: lvs. broader, glabrous when mature, margins not revolute: fr. 9–12 lines long, glabrous when mature. New Zeal.—*P. floribundum*, Wight & Arn. A small tree: lvs. lanceolate or oblong-lanceolate, glabrous, shining: fls. in terminal compound corymbs, numerous, yellow. Subtrop. Himalayas, ascending to 5,000 ft.—*P. havaii-*

ense, Hillebrand. Lvs. ample, acute, 7-10 in. long, 2-3 in. wide, sparsely to silvery hairy beneath: fls. in terminal clusters, cream-color. Hawaii.—*P. heterophyllum*, Franch. Half-reclining: lvs. medium-sized, ovate, acute, glabrous: fls. few, terminating short branchlets, light yellow. China. Offered by Franceschi for rockeries and embankments; drought-resistant.—*P. illicioides*, Makino. A handsome evergreen shrub: lvs. glossy green: fls. greenish yellow. Japan. In general appearance resembles *Illicium anisatum*.—*P. Kirkii*, Hook. f. Glabrous shrub: lvs. narrow-obovate, very thick, obtuse: fls. yellow, in terminal umbels. New Zeal.—*P. Rāpahi*, Kirk. Shrub, related to *P. crassifolium* but lf.-margin not revolute: lvs. white-tomentose beneath: fr. 8 lines long, pubescent. New Zeal. G.C. III. 26:205 (as *P. crassifolium*).—*P. tetraspermum*, Wight & Arn. Shrub: lvs. ovate, acute, 2-4 in. long, glabrous: fls. terminal, yellowish: fr. glabrous, 4-seeded. India.

HARVEY MONROE HALL.

PITYROSPERMA: *Cimicifuga*.

PLACEA (possibly derived from a Chilean name). *Amaryllidaceae*. Rare and beautiful Chilean bulbs, of difficult culture, bearing showy flowers something like an amaryllis (*Hippeastrum*), the colors being white or yellow, streaked with red.

Perianth funnel-shaped, with scarcely any tube; corona funnel-shaped, inserted at the base of the segms., deeply cut, the divisions notched, stamens inserted inside the corona; ovary top-shaped, 3-celled; ovules many, superposed; style declinate; stigma capitate, obscurely 3-lobed.—Five or six species. Botanically the peculiar feature of Placea is its cup or corona, which is smaller than that of *Narcissus*, and red instead of yellow or white. The beauty of the placeas, however, is of the *hippeastrum* type, though the fls. are not so symmetrical, for at first sight it looks as if two of the perianth-segms. were torn away. The peduncle is long and hollow.

Placeas are generally classed as autumn-flowering bulbs. Though natives of the Andes at considerable elevations, they are not hardy. The bulbs are said to lie deep in the ground in their native country, and pot culture is generally considered unsuitable for deep-lying bulbs. The bulbs go to rest about August and push up about December, flowering in May. In a pot they ought to have their time of rest, and must be buried in the soil, which ought to be very rich, but in pots they are not certain to flower. They must be planted with at least an inch of soil over their necks, and they prefer a loose soil.

ornata, Miers. Bulb 1 in. thick: lvs. 2, linear, appearing with the fls.: scape 6-9 in. high; umbel 4-6-fl.; perianth-segms. 1-1½ in. long. B.R. 27:50. Gn. 54:510.

P. grandiflora, Lem., is thrice as big as *P. ornata*, more floriferous, and is essentially distinguished by its perianth-segms., which are more acuminate and sharp-pointed. I.H. 15:574. F.S. 20:247 (erroneously as *P. ornata*).

WILHELM MILLER.

PLAGIANTHUS (Greek, *oblique flower*). *Malvaceae*. Trees or shrubs, rarely herbs, with large or small white 5-petaled flowers, little known in this country.

Bractlets none or distant from the calyx, which is 5-toothed or cut; column of stamens divided at the apex into many filaments; cells of ovary 2-5, rarely 1 or many; ovules solitary, pendulous: carpels in a single series: style-branches longitudinally stigmatose within: foliage and infl. various. Distinguished from *Abutilon* by the number of ovules.—About 12 species from Austral., New Zeal., and Van Dieman's Land. They are hardy in the most favored parts of England. None of the species is offered in America. They are known as "ribbon trees."

Lámpenii, Booth. Botanically only a variety of *P. pulchellus*, but horticulturally very much superior. Shrub, attaining 6-8 ft.: lvs. oblong-lanceolate, 4-5 x ½-1 in., sharply serrate: fls. in short, axillary leafy panicles, very numerous and crowded; styles very small. Van Dieman's Land. G.C. II. 22:201.

pulchellus, Gray (*Abutilon pulchellum*, Sweet. *A. pulchrum*, Don). Tall shrub: lvs. lanceolate, cordate, acuminate, 2-3 in. long, coarsely crenate: fls. few,

clustered along rachis of axillary racemes; ovary 5-celled. Austral. B.M. 2753 (as *Sida pulchella*).

P. betulinus, A. Cunn. **RIBBONWOOD**. Tree, 30-60 ft. high, with trunk sometimes 3 ft. diam.: lvs. of mature plants 1-3 in. long, ovate or ovate-lanceolate, acuminate: fls. small, unisexual, in terminal or axillary decompound panicles, yellowish white. New Zeal. Said to be used by the Maoris for making rope and twine.—For *P. Lyallii*, Hook., see under *Gaya*, Vol. III, p. 1319, additional illustrations of which are G. 32:543; 35:677. G.M. 55:572. Gn. 44:28; 75, p. 372. G.C. III. 4:209; 41:332, 335. H.F. II. 13:361.

WILHELM MILLER.

PLAGIOBOTHRYS (Greek, *plagios*, sideways, and *bothros*, pit or hollow; wherefore the name should have been written *Plagiobothrus*). *Boraginaceae*. Several species of low-growing commonly diffuse annuals from W. Amer., with small white fls. Here belongs *P. nothofolius*, Gray, from Calif. to Wash., which was once advertised under its synonym *Eritrichium nothofulvum*, Gray. This plant has no horticultural standing.

PLAGIOGÏRIA (Greek, *oblique* and *round*, alluding to the oblique ring around the sporangium). *Poly-podiaceae*. Warm-country ferns, formerly included as a section under *Lomaria*.

Sori inserted on the more or less thickened ends of the forked side-nerve, finally often confluent, usually covered by the revolute margin; indusium lacking; sporangia long-stalked with a complete oblique ring; spores tetrahedral: lvs. tufted, simple-pinnate, dimorphous; petiole fleshy-swollen at the base, the upper side of which has 3-6 spongy protuberances; sterile lvs. serrate; fertile lvs. smaller, mostly entire.—About 10 species, in tropics of New World, in the Philippines, Formosa, S. China.

costaricensis, Mett. (*Lomaria costaricensis*, Baker). A plant requiring warmhouse cult.: sterile lvs. 1 ft. and more long and about half as wide, with entire falcate lfts. which are less than ½ in. broad and united at their bases, thereby forming a winged rachis; fertile lvs. 1½ ft. long and 6 in. broad, with contracted lfts. Costa Rica.

PLAGIOSPERMUM: *Prinsepia*.

PLANERA (after J. J. Planer, 1743-1789, professor of medicine at Erfurt; author of several books on botany). *Urticaceae*. **WATER-ELM**. Monotypic genus, allied to *Ulmus* and *Celtis*: lvs. pinnately veined, alternate: fls. polygamous, with deeply 4-5-lobed calyx; staminate fls. short-stalked, in clusters at the base of the young branchlets, with 4-5 stamens; pistillate or perfect ones on rather slender stalks, 1-3 in the axils of the lower lvs.: fr. a small muricate nut. The only species is *P. aquatica*, Gmel. (*Anonymus aquaticus*, Walt. *P. ulmifolia*, Michx.). Small tree, sometimes to 40 ft.: lvs. short-petioled, somewhat unequal at the base, ovate to ovate-oblong, unequally serrate, glabrous at length and somewhat leathery, 1½-2½ in. long; fr. oval, ½ in. long, with irregularly crested fleshy ribs. April, May. S. Ill. and Ky. to Fla. and Texas. S.S. 7:316. R.H. 1903, p. 351. This tree is not in general cult. and has little to recommend it as an ornamental plant. It would not prove hardy N. It probably thrives best in moist soil and is prop. by seeds sown soon after ripening in May and by layers, also by grafting on elm. The plants sometimes cult. under the name of *P. aquatica* belong either to *Ulmus campestris* var. *viminialis*, *U. parvifolia*, or *U. alata*, to which the true Planera is similar in foliage, or to some other small-ld. elm.

P. acuminata, Lindl.=*Zelkova serrata*.—*P. carpinifolia*, Wats.=*Zelkova ulmoides*.—*P. crenata*=*Zelkova ulmoides*.—*P. Keckii*, C. Koch=*Zelkova serrata*.—*P. repens*, Hort.=*Ulmus pumila* or *parvifolia*.—*P. Richardi*, Michx.=*Zelkova ulmoides*.

ALFRED REHDER.

PLANE-TREE: *Platanus*.

PLANER-TREE: *Planera*.

PLANT (Latin, *planta*). A plant is a living organism consisting of one or more cells, some of which, in most of the higher forms, contain a green substance—chlorophyll—by the aid of which they are able in the light to construct carbohydrate food-matters (as sugar, starch, and the like) from carbon dioxide and water. The cell protoplasm assimilates or uses these carbohydrates and is nourished by them, and from the elements they furnish it is able to make cellulose, the substance which walls it in and gives strength and solidity to the plant. Animals do not (as a rule, at least) have chlorophyll, and cannot construct carbohydrates from carbon dioxide and water, and the same is true of some plants, as explained below.

Green plants absorb carbon dioxide from the air, and in the process of carbohydrate formation they give off a certain quantity of oxygen. However, in the further chemical activities of their cells, oxygen is absorbed and carbon dioxide is given off. In the plants which are not green (as in animals, also) the first process is wanting, while the second takes place. These facts have given rise to the view that plants and animals are quite opposite in their physiological relations to the surrounding air. They should not be contrasted, however, in this way; it is more exact to say that green plants have two important nutritive functions, namely (1) carbon absorption and fixation (technically photosynthesis), and (2) assimilation of food matters. Respiration—the process in which oxygen is absorbed and carbon dioxide is given off—occurs in all plants and animals.

With this general definition of a plant before us we may say that while some lower plants are minute single cells, or rows of cells, and others are flat, expanded and often irregular growths, in all of which there is a marked simplicity of structure, in higher plants we find the plant-body composed of well-defined roots, stems, leaves, flowers, fruits, and seeds. The lower plants referred to perform all the functions necessary for their continued existence, and are not in any sense "imperfect plants," as the older botanists used to denominate them. The difference between lower and higher plants is that the functions of the former are performed by fewer organs, while in the latter there is an approach to one organ for every function. Still it is true that some organs even in the highest plants have more than one function: so that it may be said that plants are theoretically capable of considerably higher development than they have yet attained. Thus while the chief function of the root may be for the absorption of food-matter, it commonly has in addition a holdfast function, and may become an organ of storage also. So, also, while the chief function of the leaf is to supply green cells for carbohydrate making (photosynthesis), it may be used as a storage organ (as in cabbage leaves), or even for making the plant more conspicuous (ornamental), as in many euphorbias. Even the flower usually unites two functions (that of fertilization and of showiness), which in more highly specialized forms are separated, as in the wild snowball where the large marginal flowers are for show but are sterile, while the small inconspicuous central flowers are fertile.

One more thing must be included in our general conception of the plant. While it is true that plants are normally, and typically, green in color, there are many plants which have so changed their food habits that they are no longer green. Thus parasitic plants that secure carbohydrates from living organisms, having no need of chlorophyll, are not green, and the same is true of saprophytic plants (those that get their food from dead or decaying organisms), which are also destitute of a green color. This is the explanation of the fungi, lichens, bacteria, and some flowering plants (e.g., dodder, Indian pipe, beech drops, and the like). Such plants are more or less degenerated, and are physiologically like animals, but they still retain enough of the

typical plant structure so that one is rarely at a loss where to place them.

C. E. BESSEY.

PLANTAGO (the Latin name). *Plantaginaceæ*. A group of 200 or more species of annual and perennial herbs or subshrubs occurring in many parts of the world. It is a weedy genus, and only two or three species have any economic or commercial value worth mentioning.

They are generally known as plantains, although this name is also applied to certain bananas (see *Musa*), which are plants of widely different kind. *P. lanceolata*, Linn., or ribwort, is sometimes used in pasture mixtures abroad, because it affords more or less spring pasturage on dry and sterile soils. The seed is offered by American seedsmen for feeding birds, but not for sowing. In this country, however, it is one of the worst of lawn weeds, thriving in our hot dry soils when grass kills out. The best remedy for it is to secure a better stand of grass, and this is made possible by making the ground rich and so treating it that it will hold moisture. *P. Coronopus*, Linn., the buck's-horn plantain, native to Eu., Asia, and N. Afr., is sometimes eaten as a pot-herb (see p. 1411). It is a low perennial, with linear-lanceolate often pinnatifid lvs. It is not in the American trade. *P. cordata*, Lam., of the E. U. S., has been offered by dealers in native plants as a subject for colonizing in bogs and margins of ponds. It is perennial, with a stout root-stock, large cordate-orbicular shining lf.-blades, and a slender spike rising 1-2 ft. high and bearing small pinkish fls. with exserted style and stamens. *P. major*, Linn. (Fig. 2990), is a very common doorway weed. Var. *variegata*, Hort., a variegated lf.-form, is offered in England. *P. maxima*, Jacq., from Siberia, said to have white feathery spikes, has been intro. into England. There are about 20 native or naturalized species in N. Amer. *Plantago* is the typical genus of the *Plantaginaceæ*, a family that contains two other genera, *bitypic* and *monotypic*,—*Littorella* in Eu. and N. N. Amer., and *Bougueria* in the Andes of Peru and Chile.

PLANTING. This *Cyclopedia* considers two classes or kinds of horticultural work,—the growing of plants, and the identifying of plants. The latter purpose runs through every generic entry, throughout the alphabet. The instructions for growing are combined with these generic entries, and are also extended in many separate articles, under the popular names of the plants themselves, as Rose, Strawberry, Carnation, Lettuce, Mushroom, and many others; and they are also displayed in class articles, as *Alpine Plants*, *Kitchen Gardening*, *Annuals*, *Biennials*, *Perennials*, *Herbs*, *Orchids*, *Palms*, *Arborealiculture*, and many others.

At this point, another set of class articles is assembled, with the purpose to bring together such instruction as is commonly associated with what is known as "planting,"—with the use of plants in the open and particularly in relation to their uses as a part of a landscape development. In connection with this symposium, the reader will naturally give special attention to the assembly on

Herbs in Vol. III and on Landscape Gardening in Vol. IV. Inasmuch as trees are discussed under Arboriculture and herbaceous plants under Herbs, the present treatment is mostly of shrubs. (Figs. 3001-3005, 3011-12, are adapted from "Garden and Forest.")

The relation of planting to the fundamental design.

It is the business of the landscape architect to combine beauty and utility into a harmonious composition. The artistic aim in the practice of landscape architecture is to produce beautiful pictures. To achieve such pictures, the creative imagination must be controlled by familiarity with the accepted canons of design. Good design in landscape work must be based on the fundamental principles of art and the laws of nature. Fitness, proportion, variety, mystery or intricacy, unity, and harmony,—all these must be considered.

While it is the aim, in creating landscape gardens and parks, to produce natural effects, the best results are not necessarily secured by a mere imitation of nature as it happens to exist in a given locality. It is possible to modify nature to fit artificial conditions; and by changing the scale, by adding new features, or making different combinations, compositions may be produced which have all the charm of a natural scene, yet surpass nature in beauty and interest. Varied emotions are produced by different compositions. Sometimes the mood is gay, as in flower-gardens. Awe, wonder, and admiration are produced by the large natural features,—rocks, cliffs, cañons, waterfalls, the mountains,

and the sea. Mystery and intricacy are conceived by rambles through the dense woods and jungles. Rest, peace, tranquillity are suggested by certain woodland scenes, a sheltered lake, or a meadow with a meandering stream. The sense of deliberation, dignity, and maturity is produced by the stately arched trees of avenue or mall, and by groves of matured trees.

Many laymen and artists think of landscape architecture only as a decorative art; and to their minds planting is of value only in so far as the foliage hides some ugly foundation, softens hard lines or relieves bare spaces, screens some unsightly view or forms a setting for an architectural feature. Sculptors and architects especially are prone to think that the most charming natural parts of our public parks are suitable sites for memorials in stone and statues in marble and bronze. They reason that the spreading branches of the trees and the background of foliage will enhance the beauty of their work of art. Their thought is of their own creation and they fail to realize that by introducing an artificial object, no matter how beautiful it may be in itself, the harmony and beauty of the natural scene may be destroyed.

From the point of view of the landscape architect, planting is not merely a superficial decorative process. He considers the arrangement and disposition of the foliage-masses as well as the modeling of the earth's surfaces to be fundamental in landscape design. Necessary buildings, roads, paths, and other artificial features must be provided for use and enjoyment; but the best design is the one that succeeds in effectively obscuring or subduing these necessary objects in the landscape and still provides fully the facilities required for use, shelter, and other enjoyments of the people.

While design is the main consideration in creating a landscape, nature, life, and time are necessary for the completion of the design and the full development of its beauty. The beauty of a landscape is dependent largely on the green living things, as trees, shrubs, grass; but the success of the picture is due more to the disposition and arrangement of the material than to the materials themselves. Therefore, it sometimes happens that a thorough knowledge of horticulture, especially when this knowledge is combined with great enthusiasm and, perhaps, with an added interest in botany, is a decided handicap to the success of the amateur designer. The horticultural features are over-emphasized at the expense of the composition. Many places and parks that were originally well designed have been robbed of their charm and beauty and landscape effects, because of the interest and enthusiasm on the part of gardeners, owners of estates, or park commissioners in horticultural things. In the conviction that they are embellishing the beauty of a glade, valley, lawn, or meadow, they proceed to cover these open spaces with rare specimens of trees and shrubs, thus

2992. A series of back-yard improvements, exhibiting pride in premises.

destroying the arrangement. Open areas should not be considered as waste space.

A landscape design may be either formal or natural. The character of the planting of formal gardens and terraces and the embellishment of buildings by planting should be in harmony with the type of architecture and with the nature of the site of the garden and its relation to the house. In the design of a natural landscape, the three general classes of planting material—woods, shrubbery, and lawns or meadows—should intermingle to a certain extent, and yet be so arranged as to present in general an open central feature of lawn or meadow, with the masses of foliage surrounding. This provides unity, and the broad masses of light and shade produce a pleasing composition.

The outlines of the lawn or meadow should be irregular, and their limits somewhat obscured. Now and then trees or groups should be introduced, especially near the boundaries of the lawn, to add diversity and interest; the

shadows will relieve the monotonous expanse of light.

To design effective plantations, a knowledge of planting material, a conception of composition, and imagination and taste are requisite.

In planting, the landscape architect is more concerned with the color, texture, form, and size of flowers and foliage than with botanical families or with cultural requirements of plants; still, in order to design places and parks that will be in harmony with the general surroundings and to use material that will thrive, he must be familiar with the indigenous plant material, and know what soil conditions and locations are suitable for their peculiar needs. However, it must not be assumed that only those trees, shrubs, and plants that grow in the immediate vicinity may be used; but, in the creation of the natural landscape, the native plants and trees should predominate.

The most important planting material used by the landscape architect is "grass seed." Ordinarily grass is not considered in the general conception of planting, but most landscape architects and many laymen realize that grass in the form of lawns and meadows is the most significant feature of our naturalistic landscapes. Its value when used within formal lines, the tapis vert and terrace, are generally recognized. It is not far-fetched to say that grass is the most important planting material used in the creation of landscape in this climate.

Lawns and meadows provide color, texture, motion of the waving meadows, the play of light and the shadows of clouds and trees. The covering of grass over earth enhances the beauty of the contours and the modeling of the earth's surfaces—knolls, valleys, glades, and plains. The effects of space, breadth, dignity, and distant views are dependent upon the proper framing of open spaces with foliage. Indeed, open spaces, whether in the form of sea, lakes, or streams, lawns or meadows, sand-dunes or even paved spaces, are one of the most important elements in landscape design.

C. F. PILAT.

Village improvement in relation to planting.

Village improvement is a branch of civic art. Civic art in turn may be defined as the conservation, improvement, and utilization of public property. Village improvement thus takes its place alongside of town-planning, country-planning, the development of garden cities, and other work of a similar nature. The public-property test may be rather strictly applied to all branches of civic improvement, including village improvement, for while village improvement does in fact undertake extensive work upon private grounds, this is undertaken solely in the public interest.

In village improvement it is rather important to fix attention upon the village or small town as a permanent unit. For the most part, the small towns of America have had notable ambitions for growth. Each one has intended to grow up into a state capital or a large manufacturing center. On this account it has been impracticable to make intelligent plans for the actual circumstances, that is for an indefinite period of existence without further expansion. The growth problem, while it is largely a psychological factor, is a very important one in connection with village life and development. It is a problem which should be seriously faced. Each community should understand its actual circumstances and its ambitions, if it is to make any real improvement in its condition.

Inasmuch as civic improvement is based upon public property, the scope of its work may be outlined rather strictly by the extent and character of property owned in any community. The more important types of public property, with some discussion of the problems attached to their improvement, are taken up herewith. The illustrations and plans (Figs. 2991-2996) suggest some of the important phases, particularly as related to planting.

Streets.—Streets and public roads constitute perhaps the most important mass of public property in each community. They are absolutely indispensable and have a very high monetary value judged by any scale whatever. Road and street improvement is always looked upon as a practical benefit to the community and may, therefore, naturally and properly become the starting-point of general village improvement. Street improvement should be studied with reference to (a) location, (b) design, (c) construction, (d) furnishings, (e) maintenance. (a) The location of streets and roads is generally looked upon as an inviolable accomplishment, yet many roads and streets can be, and should be relocated, or altogether abandoned. In other places new streets should be provided. (b) Some streets ought to be straight, some ought to be curved, some ought to be wide, some should be narrow. Some should be provided with wide grass verges, with rows of trees and with parkings. In other parts of the village, streets should have no such furnishings. In fact, each street should be made a study by itself, and should be properly designed

2994. Plan for main residential village street.

2993. Planting plan for a business street in town.

LXXXIX. Planting.—Rhododendrons in a landscape composition.

for its special conditions. (c) All streets, of course, should be well constructed. Macadam and tarvia are good materials. However, there are many streets which do not need such expensive improvement. The problems of street construction are generally fairly well studied, but of course, final and perfectly satisfactory results are never achieved. (d) Besides the trees in the street, there are many other things to be considered, such as guide-posts, letter-boxes, and especially telephone, electric-light, and trolley poles. All these furnishings should be made as satisfactory as possible. Especially in the matter of poles the ideal is to reduce their number to the minimum. (e) All streets need to be kept in good repair and to be kept clean. These are always important matters, but they cost considerably more care, labor, and money than most persons imagine. Village improvement can nearly always make considerable progress in this one point of keeping the streets clean and in good condition.

Transportation may be reckoned as the second great problem of village improvement. The development of attractive railroad station-grounds, by proper planting of trees, shrubs, and grass is a matter always to be looked after. In rural communities, at the present time, with the large development of trolley service, the design and location of first-class trolley waiting stations becomes a matter of great importance and should receive careful attention.

Schoolhouses and school-grounds constitute a very important type of public property, and every campaign of village improvement should look after them carefully. School-grounds should be kept clean and orderly and should have some tree plantings. Wherever possible there should be grass, but the improvement of school-grounds with flower-beds is almost out of the question. Perhaps the most insistent problem of the improvement of the school-grounds themselves, lies in securing adequate area, which should be from 2 to 5 acres for each school instead of the $\frac{1}{4}$ acre commonly allowed.

Playgrounds are very much needed in every village and rural community. The problems connected with them are, (1) to secure the necessary allotment of land; (2) to have this ground properly planned and developed; (3) to have the play properly supervised. The embellishment will consist chiefly of large trees for shade and to improve the appearance. Flower-beds and borders are quite out of place on playgrounds.

2995. Plan of country road, showing suggested arrangement of trees, shrubs, and flowers.

Reservations of several sorts are needed in every village. These should be primarily for recreation, but should include also places of historic importance or those of great scenic beauty.

Public buildings, including churches, libraries, grange halls, town halls, and the like, must be of the best character in order to secure proper results in village development. All these public buildings should be studied with reference to adaptation to use, proper location, grouping with other public buildings, good architectural design, and substantial construction. The grounds about these public buildings should be developed to the

best possible advantage. As a rule, shady lawns with good substantial trees give the best result.

Home-grounds are of prime significance in every community and every village-improvement society should undertake to secure the best treatment of them possible. Neighborhood competitions are useful to this end but sound horticultural instruction is always necessary.

The more strictly horticultural phases of village improvement, therefore, are the planting and care of trees, the development of grass areas, especially lawns, home-garden improvement with some emphasis upon front yards, and school-garden enterprises of several sorts.

In the care of trees on public streets and grounds, a competent tree-warden is greatly to be desired. When state legislation provides for such an officer he should be chosen with great care and supported with reasonable appropriations of public funds; and in states where tree-wardens are not provided for by law such legislation should be secured as soon as possible. The Massachusetts law is perhaps as good a pattern as any.

Street trees are subject to severe injuries even beyond the liability of other shade trees, such as the damage from leaky electric wires and gas-pipes, gnawing of horses, and sometimes the attacks of ignorant linemen putting up wires. Add to these the usual menace of insect attacks, such as elm leaf-beetle, leopard moth, forest caterpillar, gipsy moth, and the like, and it will be seen that the protection of valuable street trees is a real undertaking. (See *Diseases and Insects and Arboriculture*.) The improvement of home-grounds and similar areas is treated elsewhere. (See *Landscape Gardening*.)

The peculiar agent of village improvement is the village-improvement society, but other organizations are equally useful. Woman's clubs and boards of trade are usually effective. Very often smaller groups which undertake to cover only a single street or a single small neighborhood accomplish the most intensive and satisfactory results. As a rule it is undesirable to form a new organization in any community for village improvement. It is better policy to seek the coöperation of the various existing societies. In certain circumstances these can be federated in a way to cover the problem satisfactorily.

Four factors must always coöperate in order to secure satisfactory results in civic improvement of any sort. These factors are (a) local initiative, (b) expert advice, (c) time, and (d) money. (a) It is always necessary to have some energetic local society or group of men and women who will stand behind any improvement proposition. Without this local initiative nothing can possibly be done. (b) In addition to this it is usually desirable and sometimes positively necessary to have work undertaken on the basis of practical plans drawn by experts from outside the community. The outside assistance is valuable even when no more expert than advice which might be secured within the community itself. Good

2996. Plan for country road four rods wide.

plans are, however, always indispensable. (c) It then requires a considerable amount of time to carry out important improvement projects. It has been estimated that from six to ten years are always necessary in order to bring a community around to a proper understanding of its problems, and to secure sufficient unity of opinion to accomplish valuable results. (d) Money is

2997. Planting without composition.

very important, but not one-half so important as persons usually suppose. As a rule the money can be raised whenever the community is convinced, as a whole, that the proposed improvement is worth while. It is best under all circumstances to have public property paid for and improved from public funds. This means that the money should be voted by the people themselves from the public treasury. The ordinary way of raising money for village improvement, by raffles, fairs, and other voluntary means, is wholly unsatisfactory. It can accomplish only trivial results.

FRANK A. WAUGH.

Shrubbery in the landscape.

Shrubs and bushes have two values: an intrinsic value as individual or single specimens; a value as part of the structure or design of an ornamented place. As individual specimens, they are grown for the beauty of the species itself; as parts of the landscape, they are usually grown in masses, constituting a shrubbery. It is often advisable to plant shrubs as single specimens, in order to produce the characteristic beauty of the species; but the temptation is to plant exclusively as isolated specimens, and the emphasis needs, therefore, to be placed on mass-planting.

Plants scattered over a lawn destroy all appearance of unity and purpose in the place (Fig. 2997). Every part of the place is equally accented. The area has no meaning or individuality. The plants are in the way. They spoil the lawn. The place is random. If the shrubs are sheared, the spotted and scattered effect is intensified. Rarely does a sheared shrub have any excuse for existence, unless as a part in an artistically designed formal garden.

A mass or group of planting emphasizes particular parts of the place. It allows of bold and broad contrasts. It may give the place a feeling of strength and purposiveness. The shrubbery-mass usually should have an

irregular outline and it often contains more than one species. Thereby are variety and interest increased. Fig. 2998 suggests the interest in a good shrubbery-mass. The shrubbery-masses should be placed on the boundaries; for it is a concept of landscape gardening that the center of the place shall be open. (Fig. 2999; also Figs. 2076, 2077, and others in Vol. IV.) The boundaries are the lines between properties, the foundations of buildings, the borders along walks and drives. Judicious planting may relieve the angularity of foundations and round off the corners of the yard. (Fig. 3000.)

Individual specimens may be used freely, but only rarely should they be wholly isolated or scattered. They should be planted somewhere near the borders, that they may not interfere with the continuity of the place and that they may have background to set them off. The background may be a building, a bank, or a mass of foliage. In most places, the mass or border-planting should be the rule and the isolated specimen the exception; but, unfortunately, this rule is frequently reversed. It is not to be understood, however, that boundaries are always to be planted or that foundations are always to be covered.

L. H. B.

The chief value of shrubbery comes from its use in an artistic way, although some shrubs have edible fruits. Many shrubs, such as lilacs, some of the spireas, gooseberries, and currants, produce leaves very early in the season and some, like forsythia, daphne, and the juneberry are covered with a profusion of blossoms at this time. From early spring until November in temperate latitudes leaves and flowers are to be found on deciduous shrubs, and from June until the following spring ornamental fruits can be seen on their branches, the red berries of the elder beginning and barberries

ending the list. Some of these fruits are so richly colored and so abundant that they can be seen from a long distance. Many shrubs, like some of the viburnums and dogwoods, attain a height of 10 to 15 feet, while others, like bunchberry and *Daphne Cneorum*, grow to a height of only a few inches. The leaves of some,

2998. A composition of shrub and tree forms.

like the chokeberry, Thunberg's barberry, the hazels, viburnums, dogwoods, and sumachs are beautifully colored in autumn. The rhododendrons, laurels, and mahonias, and the daphne already named, are examples of shrubs having evergreen foliage. Some leaves, like those of the *Salix lucida*, are glossy; others, as those of the common hazel, are hairy; some are thick, and others are thin; some large, some small; some entire, and some lobed, serrated or compound. Throughout the season the foliage of a good collection of shrubbery will present the greatest variety of color, including all the hundreds of shades of green as well as yellow, white, gray, and purple. Even in winter shrubbery is wonderfully attractive in appearance from the gracefulness of its stems and branches, and from the color of its bark. With the right selections, it will serve almost as well as evergreens to shut out from view fences or other low unsightly objects.

This great variety in foliage, flower, fruit, and habit of growth makes shrubbery adapted to very extended use in the development of landscapes. It is especially appropriate along the boundaries of ornamental grounds (Fig. 2999), upon steep slopes, and in the immediate vicinity of buildings where foliage and graceful lines are needed to connect the walls of a structure with the ground (Fig. 3000), without making too much shade. It might with advantage replace the grass upon all surfaces too steep to walk upon with comfort. The foliage of shrubs that are well established remains green when dry weather turns grass brown. The broad mass of shrubbery will take care of itself when the grass needs frequent attention. Even some level surfaces might be improved in places by exchanging a lawn covering for the covering of low woody plants. Often a broad open space over a lawn is an important feature of a landscape, since it allows extended views. Many times a landscape would be more interesting if the green underneath this open space were produced by a broad mass of shrubbery, like a miniature forest, instead of grass.

In planting borders or groups of shrubs, the ground to be occupied by such a group should be entirely spaded over or plowed. Perhaps no better advice could be given than to prepare the soil as it should be prepared for a field of corn. The bushes should then be planted so that there is room for about two years' growth before their branches intermingle. If placed closer they would have a crowded appearance from the start and would

not join their branches as harmoniously as when the new growth is allowed to choose its own position. If placed farther apart the effect is also bad. Occasionally a single shrub at the margin of a belt may stand out almost by itself, but generally the effect of a group should be that of a continuous mass of varying foliage.

3000. An effective planting against a hard corner.

In arranging different shrubs, the taller-growing kinds should generally be placed in the center of the group, and the lower species along the border, the space being graded from the highest to the lowest. The reason for this arrangement is that the lower plants would be killed by the shade of the larger ones if placed back of them, and moreover would not be seen; but one should avoid too uniform a slope. For example, in a continuous border there should be places where shrubs of larger size occupy the full width so as to bring growth of considerable height into the lawn. The arrangement should be varied so as to avoid all monotony, but in securing this variation a mixture of miscellaneous shrubs of all kinds does not give so good an effect as broader areas of single species or genera slightly interspersed at the margin with shrubs of another kind. Straight rows should be avoided. A laborer or a novice when told this will arrange the plants in a zigzag manner, thinking that he is placing them irregularly, the result often being almost the same as that of two rows. If the group is being planted along a straight line, as the boundary of a lot, the distances of the successive plants from this line might be somewhat as follows: 2 feet, 4 feet, 5 feet, 3 feet, 1 foot, and the distances apart, measured parallel with a fixed line, should vary also.

The ideal condition of a group of shrubbery is to have all the individual plants healthy, so that the foliage will appear fresh and of good color. This foliage should extend down to the surface of the adjacent lawn or walk, and shade the ground underneath so completely that nothing will grow there. The leaves which fall with the approach of winter should be allowed to remain as a perpetual mulch. The desired result cannot be secured the first year the shrubs are planted unless they are of large size and moved but a short distance. The aim in caring for a new plantation should be to secure thrifty plants, and this care, like the preparation of the soil, should be such as is given to a field of corn.

Very little trimming should be done. If a bush is tall and spindling it may be well to cut it off next to the ground and allow it to sprout again. If there is any dead wood it should, of course, be cut off. But when a shrub is healthy and vigorous, let it grow in its own

2999. The open center and margined sides.

graceful way. If it encroaches upon the walk, cut away the encroaching branch near the root so that the mark of the knife will not be noticed. Such treatment will help to retain the winter beauty of the branches.

3001. A protection of shrub and tree forms.

verdurous landscapes that please him will have their furniture of shrub and bush.

O. C. SIMONDS.

Woods in the landscape.

The principal elements of landscape are atmospheric conditions, irregularities of the earth's surface, water, artificial constructions, herb and shrub ground-cover, and the woods. In the United States the great areas east, west, north, and south of the treeless prairie regions were mostly in evergreen or deciduous woods. Industries, habitation, and cultivation have divided the great wooded areas into small wood-lots and into forests that are for the most part broken into sprout- and tree-growth areas as the cordwood or timber is harvested in thirty- to sixty-year periods. The corresponding landscape modifications to that offered by this cutting of the forests is presented by homestead tree plantations that have broken the great unobstructed herb-covered prairie sweeps into series of tree-framed vistas. This offers a striking example of the importance of woods in landscape.

3002. A verdurous landscape of tree and shrub.—Thiergarten, Berlin.

In the arid regions of the West, the woods are confined to a meager growth in places made moist by springs, streams, or by irrigation, to mountain slopes and valleys, and to the humid regions and mountain valleys of the Northwest. In this last section, the region of sequoias, pines, spruces, and firs, are the state-liest cone-bearing forests of the continent. The white and Norway pines of the Northeast and the long-leaf pine of the Southeast, only approach the Pacific Coast Range trees in grandeur.

As landscapes of the highest types of beauty include woods, and as wood has a high economic value, one should determine how best to save woods for their beauty and to set aside the areas that should be harvested. To fix upon areas to be kept in woods and those to be used for agriculture, industries, and habitation, economic surveys should be made of large areas. In such surveys land that is ill fitted for cultivation should be outlined and set aside in public reservation, with a view to maintaining it largely in forests. Land that is suitable for cultivation, habitation, and industries should be set aside for these purposes, and the forests stripped therefrom as the land is needed. This country-side planning is already being worked out in the study of city and county. The plans of the regions about Boston, Massachusetts, in Essex County, New Jersey, and Cook County, Illinois, and of such towns as Hopdale, Massachusetts, represent studies in which forest areas are set aside, in public reservations, and the forest growth encouraged thereon.

It is not to be assumed that such forests are without other economic values than the recreation they offer to many persons. It has been found possible in the development of such areas to increase the beauty of the forests and to secure a money-return that will nearly, if not quite, cover the cost of the cutting from the sale of forest-thinning products. It is likely that under wise management such forests can be constantly increased in beauty with little or no burden of cost.

In the areas that are assigned in the economic study of a region for other purposes than permanent forest holdings, the existing forest growth may often be continued for many years as the principal crop, or new forests may even be planted and grown before the time comes to cultivate the land in annual crops.

In the development of woods in landscape, the work can be performed in such a way as greatly to increase the beauty of the existing growth, which now is seldom the primeval growth, by thinning to develop the finest specimens and the finest groups of trees. A selection can also be made in the cutting to increase the dominance of different species in different localities. Cutting may often be made to open vistas and wide views from particularly attractive viewpoints. It can also be made to develop more attractive sky-lines and foliage-masses as seen from valley viewpoints or from hilltop and ridges to distant hills and ridges.

The larger factors of beauty in landscape and the economic values of woods are of interest to the general public. To the individual owner of estates and home-grounds the woods have a more intimate and personal interest. Such owners are concerned about the protection against drifting snow, bleak wind, and hot sun, a shelter for the bird-life that protects the crops, a setting and a background for their home buildings to merge them into an agreeable landscape picture, a ramble and a picnic place where the wild flowers, the fruits, and the autumn leaves can be found by the children who love the woods. The wood-lot is also a place where many sticks of timber for special purposes and some

cordwood will be secured in the cutting from year to year of the weaker trees that are overtopped by their neighbors, and from thinning that must be made if the highest types of woodland beauty are to be developed. Bear in mind that the wood-lot in good soil may produce a cord of wood to the acre each year.

3003. A good open area, with attractive shrub forms and tree forms.

Fortunate is the owner who has an established wood-lot, and especially if he appreciates and takes wise advantage of its utility and beauty. As woods would be included the thicket of few trees in the little town lot as well as the acres of trees on the large estates, because in the cool shade and leaf-mold soil of each the same plants and bird-shelters may be established. When there is no wood-lot one must plant either evergreen or deciduous trees to make one. If the home lot is a small one and it is desired to have a little wood-lot high enough to walk under at once, at reasonable cost, tall slender collected or nursery-grown trees may be planted close together and then thinned as they grow.

If a shelter-belt for winter is the most important consideration, use such cone-bearing evergreens as the pines, spruces, hemlocks, junipers, arbor-vitæ, cypress, the last three for a narrow belt, or in the South and on the Pacific coast, such broad-leaved evergreens as the magnolia, eucalyptus, camphor tree.

It should be known that undergrowth and ground-cover plants with attractive flowers cannot be so easily established under evergreens as under deciduous trees; also that among the deciduous trees are more rapid-growing species with attractive flowers and fruit.

To grow a very interesting wood-lot in a few years from the small seedling plants that can be secured in large quantities at low cost, such plants would be set from 3 to 5 feet apart. At this distance they soon shade the ground so much with foliage as to kill out ordinary weeds and give encouragement to the more attractive woodland plants. Furthermore, close planting will force a rapid growth in height. In the selection of plants, about a third would be made up of the quick-growing low-cost species such as poplar, soft maple, negundo, catalpa, locust, and in warm sections the eucalyptus, pepper tree, grevillea. Another third would be made up of the slower-growing more permanent trees, such

as oak, maple, and magnolia. The last third would be of such undergrowth, shrubs, and small trees as the flowering dogwoods, red-bud, benzoin, viburnums, white fringe, rhododendrons, azaleas, callicarpa, manzanita, and madrona. Woodland ground-cover plants may be established by bringing them in from the woods with an abundance of the natural leaf-mold soil retained about their roots.

The location for the wood-lot is at the point near the home buildings where it will best serve such purposes as are referred to early in this article, but as open land in this position is very valuable for farm uses the lot should not be large; elsewhere on the farm the wood-lot should occupy land least suited for annual crops, such as the very steep slopes and the rocky or barren areas.

Aside from woods themselves, tree forms have their special values in providing structural features in a landscape, combining well with architectural forms and affording good backgrounds and boundaries. Strip the trees from such constructions as shown in Figs. 3004 and 3005 and note the effect.

WARREN H. MANNING.

Wild-gardening.

Wild-gardening is the art of arranging and growing colonies of hardy plants, native or foreign, so that they will look like wild flowers, multiplying with little or no care after planting. A wild-garden is not a garden that has run wild, reminding us of man's neglect; it is a poetic suggestion of the beauty of nature untouched by man. Beginners commonly suppose that wild-gardening is merely the cultivation of native flowers, as in a small border. Such an effort is worth while, but it is rarely artistic and can hardly be called wild-gardening. The main idea of the latter, originally, was to naturalize foreign flowers in larger masses than those of the garden. Wild-gardening is, therefore, a branch of landscape gardening which aims to reproduce the largest floral effects of nature with the least suggestion of man's interference.

The large facts in wild-gardening are: (1) the place or location for it; (2) the composition, as part of the landscape; (3) the kinds of plants; and (4) the small

3004. Tree forms in relation to informal architecture.—House in Japan.

or incidental effects of clumps and nooks here and there. Fig. 3006 shows a wild-garden composition; ordinarily, a wild-garden is supposed to be merely "wild" or growing at random, as in Fig. 3007, and this effect is sometimes much to be desired. The nook or corner effect of planting (4) is shown in Fig. 3008, representing a rear screen.

Wild-gardening as a distinct department of floriculture first came into popularity about 1870, when "The Wild Garden" was written by William Robinson. Robinson's first aim was to introduce more variety into English gardens, which were monotonously gaudy in the Victorian era. Because of their greater showiness, tropical bedding-plants had driven hardy perennial flowers out of fashion. Robinson put the border on an artistic plane by paying more attention to grouping, color schemes, and new varieties; he popularized the rock- and water-garden; and he created the wild-garden. His second aim in wild-gardening was to reproduce some of the loveliest floral pictures of the

3005. A background protection for an architectural construction.—
Temple entrance, Nikko, Japan.

North Temperate zone which demand freedom from the garden inclosure. A third aim was to make a place for thousands of plants worth growing that are banished from conventional gardens because they have small flowers, a short season, or are unsightly when out of bloom. A fourth aim was to satisfy the universal craving for wildness.

The areas most commonly used for wild-gardening are woods, meadows, and orchards. Unfortunately, orchards cannot usually be kept in grass for many years, as in Europe. Those who are the fortunate possessors of waterside, bluffs, rocks, or sandy wastes have special opportunities for wild-gardening. Those who are confined to city lots can merely suggest the spirit of wild-gardening in lawns and borders.

The finest effects in wild-gardening are suggested not by book-study but by nature-study, paying special attention to grouping and massing. For example, if the problem is to cover a bank, the books suggest locust, willows, or other suckering plants. The beginner then covers the bank exclusively with locusts or willows, which produces an artificial or gardenesque effect. Nature rarely adopts a one-plant solution of any problem. She generally grows three or four crops on the same ground, e. g., tree, shrub, and vine, or shrub, carpeting-plant, and bulb.

If one follows the nearest river-bank for a mile or so, the finest combination may be buckeye, wild gooseberry, and American bluebells, or sumach, blue phlox, and adder's-tongue. Such combinations always give more variety than one-plant solutions, generally more

color, and look wilder because they represent a mode of living worked out by ages of struggle. When one combines roses, lilacs, and peonies on a sand-hill, the plants look unhappy, especially in August, but if one plants red cedar and bayberry the plants soon look as if they had been there from time immemorial. The skill of the wild-gardener lies in detecting plant associations that will solve each practical problem and look as if they were hundreds of years old.

In massing plants so as to imitate nature the commonest notion is to scatter them indiscriminately, but this is no longer considered the surest and quickest way to produce the finest effects. The showiest floral effect in nature is the solid mass or sheet of flowers of a single kind. But this is not the finest or wildest effect. William Robinson often takes the clouds as patterns in outlining his colonies. Clouds also suggest good combinations of density and thinness in sowing seeds or planting bulbs. One of the finest floral effects in nature is the kind of massing known as "the mother country and her colonies." The object is to suggest that the flowers have sprung from seed scattered by the prevailing wind. The outlying masses, therefore, follow one general direction (without being in straight lines), and they decrease in number, size, and density as they recede from the largest mass.

Design in wild-gardening.

In the woods one generally has the greatest opportunity for intensifying the feeling of wildness, because it is often possible to shut out all suggestion of the outside world—including even the sounds of civilization. Therefore, woods are generally surrounded by an irregular belt of native shrubs dense enough to hide artificial objects from the interior of the wood, leaving openings only for the main trails. The entrances can be marked without making them too gardenesque by saving or planting any trees that naturally form a good arch or frame, as white pine often does, by planting some accent marks, such as red cedar, arbor-vitæ, canoe birch, and mountain-ash, or by training into a bower vines such as wild grape, clematis, bittersweet, or Virginia creeper. A system of trails is next established and the planting is usually made near the trails, from which the colonies are generally expected to spread gradually into the remoter parts of the wood. To secure the finest effects, however, it is necessary to plant the dramatic, or picturesque places, such as spring, brook, rocks, glades, hilltop, or outlook with the wild flowers appropriate to each situation. Wild-gardening in the woods is also known as landscape forestry.

In meadows it is possible to allow daffodil bulbs to multiply for many years, since they may not interfere with the hay crop. The foliage ripens and falls to the ground before harvest. Bulbs that bloom after harvest-time, like *Lilium superbum*, are best restricted to the edges of the meadow. But the sunny meadow generally offers the greatest canvas for painting floral pictures—daffodils by the 10,000 and narcissi either in sheets or colonies.

In fields, however, wild-gardening involves serious economic loss. Despite this fact, many efforts have been made to imitate the European grain-fields made glorious by *Papaver Rhæas*, the scarlet annual weed which is the parent of the Shirley poppies. The seed is cheap but the poppies bloom in a half-hearted fashion and vanish after a year or two.

In permanent pastures wild-gardening is limited to species that are not eaten by cattle, and the effects are necessarily scattering or spotty. On a hillside at Grave-tye, Robinson has naturalized the oriental poppy in isolated clumps of about a dozen plants. This is perhaps the most daring feat with which a wild-gardener may hope to succeed, for foreign flowers as gorgeous as this cannot pass themselves off as wild flowers. The

distant effect, however, is very spirited, and the green background saves the effort from vulgarity.

On rocks the arrangement is largely determined by the position of soil-pockets large enough to grow plants. Soil can be added, but at great expense.

The waterside offers chances for unique effects, because the boldest tree-forms and colors have a mirror,

scilla, and glory-of-the-snow. Unfortunately, they cannot ripen their foliage before the lawn must be mown, and therefore they die in a few years.

Plant materials.

There are three principles that grow out of the aim of wild-gardening, which is to grow self-supporting colonies that will look and act like wild flowers. (1) The esthetic principle is that all materials in landscape wild-gardening shall be primitive species or slightly improved varieties. This rules out all flowers that have been profoundly modified by man, such as double and round-petaled flowers of all kinds. Double daffodils thrive permanently in some meadows, but they do not look like wild flowers, as single daffodils do. May tulips and Darwins are permanent, but these also do not look like wild flowers, as do tulips with pointed petals. Cottage tulips look wilder than other late tulips, and the wildest of all is *Tulipa sylvestris*. The magnificent red flower, *Tulipa Gesneriana*, which somewhat resembles the prototype of garden tulips, is too gorgeous to look like a wild flower in the woods, but it might be used for distant effects in the meadow, if oriental poppy is considered permissible. (2) The cultural principle demands permanence in wild-gardening. Cro-

cuses, early tulips, and hyacinths are too short-lived in long grass. English books and magazines illustrate exquisite effects in March and April made by winter aconite, European cyclamen, Grecian wind-flower, and Apennine anemone, but these are too tender or difficult for the American public to naturalize. (3) The economic principle requires that the materials of wild-gardening shall be cheap, for expensive varieties are instantly recognizable and look out of place. A good rule is to pay not more than 1 or 2 cents a bulb for daffodils by the 1,000 or 500. There are twenty to thirty varieties that can be had at this rate, and they fit the woods and meadows better than the varieties that cost 3 or 4 cents a bulb.

Foreign species offer greater temptations for display than native kinds. The danger line is that between the garden and wild-garden. This has already been indicated for daffodils, which are the unquestioned favor-

3006. A wild-garden composition, showing the landscape effect.

shrubs may obscure the line where land and water meet, and amphibious plants, like the aquatic buttercup, may swim out a few feet. Also the grace of falling water can be suggested by shrubs with arching branches, or vines planted at the top of the bank. Some of the best colonies of wild flowers are those formed by seeds falling from the top of a bank.

In roadside planting, ideals have changed greatly since 1900. Then the standard of beauty was the shrub-lined roadsides of New England. That type is rapidly vanishing from the main roads, owing to the laws against the gipsy moth and the use of the stone walls for road-making. No two miles of roadside planting should be alike. There should be shrubs enough to bring back the birds; and wild flowers arranged and maintained according to the principles of wild-gardening.

On city lots, the wild-garden shrinks merely to a border of wild flowers but differs from the hardy border of mixed perennials. The latter is a conventional arrangement of flowers, mostly of foreign origin, selected for their showy forms, colors, and succession of bloom. The border of wild flowers may become an artistic wild-garden by directly imitating some natural effect, especially a local combination or plant association. For example, in the shady border the flood-plain may be recalled by hepatica, bloodroot, meadow rue, and trillium; the swamp by cinnamon and royal fern and marsh marigold; the ravine by *Aster laevis* and blue-stemmed goldenrod. In the sunny border the prairie may be recalled by cone-flowers, compass plant, and sunflowers; the swamp by boneset, joe-pye, and blue lobelia; the riverside by mist-flower (*Eupatorium caelestinum*) and sneezeweed; the dry roadside by butterfly weed and wild bergamot.

On city lots, also, the free meadow contracts into a close-cropped lawn, but the wild-gardening spirit is expressed in numberless attempts to naturalize crocuses and the March-blooming bulbs—snowdrop, Siberian

3007. A wild-garden.

ites for wild-gardening. Dutch hyacinths are inappropriate in long grass, and they soon perish. The Roman hyacinth looks more like a wild flower, but it is better to plant English bluebells or wood-hyacinths, known to the trade as *Scilla nutans* and *S. hispanica*, and the prairie hyacinth, *Camassia esculenta*. In addition to the foreign species commended, the lemnis lily (*Hemerocallis*) is also adaptable, as its foliage harmonizes with long grass. This species looks much better beside the water than the orange day lily, which is better suited to the roadside. The most beautiful group for the water-side, probably, is the genus *Iris*. The famous iris meadow of the Royal Horticultural Society at Wisley, which has inspired much American wild-gardening since 1908, is a standard for combining the maximum of splendor with good taste. There is no difficulty in making the Siberian iris look wild, or the tall yellow iris of Europe, but the German and Japanese must be used with restraint, if at all.

It is safer to use large masses of native varieties than of foreign ones, but it is easy to overdo bee-balm, New England aster, butterfly weed, blue flag, and purple cone-flower, unless they are softened by shade, mellowed by distance, or veiled by long grass. Other American plants that are generally easy to manage on a large scale are marsh marigold, large-flowered trillium, wild

3008. A small wild-garden at the rear of a building.

blue phlox, spiderwort, *Lilium superbum*, boltonia, sneezeweed, sunflower, swamp rose mallow, and cardinal flower.

The ideal in the planting and after-care of a wild-garden is to betray no evidence of man's work. In planting bulbs, a good way is to scatter them on the ground, arranging them with the feet in cloud-like outlines containing about fifty bulbs, and then plant them where they lie, using a dibber or bulb-planter when the ground has been softened by the rains. Another method is to cut three sides of a sod with a spade, raise the grass, and insert five to seven bulbs at irregular distances. In the border the common unit of planting is a dozen plants; in the wild-garden fifty is a good unit. This is about the minimum that can be called a colony.

Wild-gardening was formerly considered essentially cosmopolitan in its spirit, as it still is in England. In America, however, wild-gardening commonly means the cultivation of American wild flowers, and the number of pure American compositions has greatly increased. Over \$6,000,000 worth of work done in the Middle West since 1901 has been inspired by the idea of restoration.

Gardening within an inclosure is a matter of personal privilege, but wild-gardening has developed a distinct code of ethics, due largely to the Wild Flower Preservation Society of America and walking clubs, like the Appalachian and Prairie, that do not permit their members to pick flowers, and a growing appreciation of wild life

WILHELM MILLER.

Bog-gardening.

Bog-gardening depends for success on the distinction between bogs and other wet or swampy places (Vol. I, p. 519). In the marsh or swamp, drainage is usually fairly regular and free; in the true bog, drainage is practically lacking or free only during the spring thaw. Because of this lack of drainage there is in all bogs an accumulation of sourness in the bog-water, which is strongly acid and dark-colored in some glacial pot-holes, more moderately so in some of the partly drained bogs of the coastal plain regions of the country. There is usually, but not always, a deficiency of lime in bog-soils, and in nature there is a very large percentage of mycorrhizal plants in them. The relation of the mycorrhizal habit of obtaining food and the acidity of the bog is a very delicate and complex one and little is actually known of it; but experience has shown such a relation to exist.

The reason for having a bog-garden is that in it many very interesting plants may be grown that could not thrive in any other situation, and many ordinary swamp plants can also be grown along its edges. For those who have an undrained area or one poorly drained, the problem of having a bog-garden almost solves itself. But the demands of others who wish to grow the many

beautiful species that will become naturalized only in such places, has led to the construction of artificial bogs. These may be of any size from a few square feet to comparatively large areas, and methods of construction must vary according to the nature of the subsoil. In places where there is a layer of hard-pan and the downward drainage is poor, it will be necessary only to dig out the desired amount, fill in enough blue clay to make the basin water-tight and then put in the mixture described below.

A more permanent and satisfactory type of construction is to make the basin of concrete, the walls and floor of which should not be less than 6 to 8 inches thick, to prevent the concrete from cracking during frost. Waterproof the concrete, and it is best to smear clay over the walls and bottom because in all concrete mixtures there is lime. The completed bog, whether of concrete or merely scooped out of the ground, should be 2 feet deep, its edges practically flush with the surrounding ground. If of concrete, sods will easily grow over it and the hard line of the rim may thus be completely hidden. One should be sure, before filling with the mixture, that the tank is water-tight, as though it were for a lily-pond. The shape of the structure, whichever type of construction is used, must be a matter of individual taste. While informality is the essence of bog-gardening, a "regular irregularity" is most to be fought against. Observation of natural bogs, their shapes and shorelines, will put the imaginative bog-gardener in possession of all the suggestions needed. As an important feature, it should be remembered that the drainage from the surrounding region should be all in, not out.

The mixture to go in the bog-garden is preferably one that has come out of a cranberry or natural bog,—muck, twigs, water, slime and all. From such a mixture, a host of very interesting bog-plants will spring up the first year and these may be isolated in clumps after the first season. A good plan when following this procedure is to let the inner part of the bog run wild, clearing a strip of a foot or two all around the edges for the cultivation of species needing, for exhibition purposes, more open spaces. Provision should be made, either in this strip or in any other open place in the bog for: (1) a place where only sand and peat soil, mixed about half and half, is found, to be used for certain plants that are described in the lists following; and (2) some small space of practically open water where the very interesting bladder-worts may be grown. The latter situa-

tion can be made by scooping out the muck for a few inches, filling in with sand and peat soil, leaving about 5 to 6 inches depth of water. For those who cannot secure muck from natural bogs, a soil may be mixed of leaf-mold, sand, and twigs and leaves of the oaks or of mountain laurel or rhododendron refuse. One should guard against getting the mixture too heavy and clayey. Sand and plenty of twigs and leaves of the species mentioned will lighten up the mixture,—leaf-mold makes it more heavy.

The management of the bog-garden requires some skill and observation. As the amount of evaporation from the surface is enormous, water must be added, either artificially or naturally. Strive to keep the bog just full enough not to overflow, thus keeping the whole sponge wet, but preventing the leaking out of the valuable acids that are the life of the bog. Both for the effect and for the good of the bog, it is desirable to cover all the open spaces in it with live sphagnum moss, which when once established, will make a delightful carpet.

Plants for the bog-garden.

Many bog-plants are very showy and worthy of cultivation. Others, such as the insectivorous kinds, are among the most wonderful plants in nature, for they have the unique distinction of being able to digest animal matter directly, a habit otherwise unknown in the realm of vegetable life. In the following account of bog-plants many are necessarily omitted, and it should be remembered that a number of purely swamp species, not mentioned here, can also be grown in bogs.

I. SHRUBS.

Rhodora (*Rhododendron canadense*), purple flowers before the leaves in April and May; 3 to 5 feet.

Swamp azalea (*Rhododendron viscosum*), white or pink flowers after the leaves in May or June; 5 to 8 feet.

Sheep-laurel (*Kalmia angustifolia*), purplish pink flowers, summer; 1 to 2 feet; also *Kalmia polifolia* in northern regions.

Leather-leaf (*Chamædaphne calyculata*), small whitish flowers along one side of the branches, May; 1 to 2 feet.

Labrador tea (*Ledum grælandicum*), white flowers in terminal clusters; leaves russet-brown below; 2 to 5 feet.

Wild rosemary (*Andromeda polifolia*), drooping white flowers, early spring; leaves silvery below; under 2½ feet.

Creeping snowberry (*Chiogenes hispidula*), prostrate, with tiny white flowers and snow berries; leaves dark, evergreen.

There are many others, but these are the best for the temperate regions of the United States. In the South many others are to be found.

II. PERENNIALS, grown chiefly for their flowers.

In any open part of the bog.

Calla palustris, a greenish flowered water arum having a conspicuous white spathe; showy and hardy.

Acorus Calamus, sword-shaped leaves and a finger-like flower-cluster; the root is the medicinal calamus.

Viola lanceolata, a delicate, very free-flowered violet with lance-shaped leaves.

Asclepias lanceolata, a deep red milkweed, very showy, and with smooth narrow leaves.

Potentilla palustris, the purple marshlocks, a sprawling rather rank bog-plant with purple flowers.

Penthorum sedoides, greenish yellow flowers in curved spikes in summer; native plant, probably not in the trade.

Orontium aquaticum, the golden-club, very early flowering, making a patch of gold in March or April.

Menyanthes trifoliata, with three-divided leaves and many conspicuous white flowers; the buck-bean is a valuable addition.

Helonias bullata, flowering in April to May; the swamp pink is our most conspicuous spring flower.

There are many asters, goldenrods, and eupatoriums that grow in bogs, as well as some gentians, but the bog species must be collected from the wild.

In wet sandy places.

Here must be grown all the species of *Xyris* or yellow-eyed grass, curious plants with long, delicate, grass-like leaves and tiny heads of yellow flowers. Also species of *Eriocaulon* or bunch-flowers should be grown here. They are not large, have sword-shaped leaves and white erect heads not unlike the everlastings. With these two must go the meadow-beauty, different species of *Rhexia* with beautiful purplish red flowers. The common *R. virginica* is the hardiest and easiest to procure.

All the plants in this class and the following are to be secured from dealers in bog-plants or collected in the wild. There are others such as *Lophiola*, *Narthecium*, and *Zyadenus*.

In open water.

The bladder-worts are different species of *Utricularia*, some with purple and some with yellow flowers, some floating on the surface and supported by air-bladders, others rooting near the edges of the pool. They are the most interesting and delicate of all bog species.

III. BOG ORCHIDS.

Many native orchids can be grown only in bogs, and from them the following have been selected, as the most noteworthy. All are perennials and may be secured from the dealers.

Calopogon pulchellus, pink-purple flowers about an inch in diameter, June and July; leaves grass-like.

Cypripedium parviflorum, a small-flowered yellow lady's slipper; raise up so that the roots will not be too wet.

Cypripedium spectabile (*C. reginæ* or *C. hirsutum*), showy lady's slipper; beautiful rose-purple or nearly white flowers; better for a little shade.

Habenaria blephariglotis, a white-fringed orchid with a showy spike; 1 to 2 feet; does splendidly in the open sun.

Habenaria ciliaris, yellow fringed orchid; very showy spike; 1 to 1½ feet.

Arethusa bulbosa, beautiful purplish pink flowers, about the last of May; 3 to 6 inches.

Spiranthes cernua, white, slender spikes; the ladies-tresses; several others, even more slender species are known.

Besides these are over forty other species which may be collected by the enthusiast. Nearly all of our most beautiful native orchids are bog-flowers. Most of them can be grown in pure live sphagnum moss.

IV. INSECTIVOROUS PLANTS.

Grown more for their peculiar habits of getting food and for their odd form than for beauty. They are of several types; some catch insects in a tube-shaped leaf, drowning them at the bottom of the cup, others have sticky hair to which the insect becomes fastened, and the most wonderful of all, the *dionæa*, actually traps its food by a contraction of its jaw-like, prickly leaves. The best insectivorous bog-plants are as follows:

With pitchers.

Sarracenia purpurea, having short purplish red pitchers, quite hardy northward, but not easy to maintain in an artificial bog.

Sarracenia rubra, the red trumpet-leaf, with tall pitchers; does very well in artificial bog.

Sarracenia flava, also with tall pitchers but yellow.

Sarracenia Drummondii, with variegated pitchers, the largest and most showy of all.

The last three must be taken in during the winter, north of Washington, D. C.; all of them grow rapidly and, if the season is favorable, will color up beautifully.

With sticky hairs.

All the species of *Drosera* have the curious habit of catching and digesting insects. They are all small plants which should be planted in masses on sphagnum moss. All native species are quite hardy and many can be secured from dealers in bog-plants. *D. rotundifolia* is the best; and *D. capensis* is a good species, but hardy only South.

With contracting leaves.

The Venus fly-trap, a low perennial with two valve-like leaves that contract whenever an insect or other irritation comes between them. Closing up rather rapidly these leaves are among the most interesting objects to see in the bog-garden. Not hardy north of Washington, D. C.

The darlingtonia, a Californian insectivorous plant allied to the eastern *sarracenia*, can be grown along the Atlantic coast only with protection, but south of Washington it should be hardy. One of the most striking bog-plants. See Vol. II, page 964. N. TAYLOR.

Water-gardening.

Water-gardening is the cultivation of water-lilies and the other aquatic plants, those that grow in water rather than in bogs or wet soil, particularly those that have floating parts.

Water-gardening is such a special form of plant-growing that it should be attempted only in the personal parts of the grounds, and where all the conditions of control can be secured. The species formerly known were mostly collected from tropical climates and were adapted almost exclusively for warm greenhouse culture and were to be found solely in botanic gardens and homes of the wealthy. However, the idea that our central Atlantic states were sufficiently warm to grow

some of the tropical varieties out-of-doors in summer was tested in the early eighties of last century by the successful flowering out-of-doors without artificial heat of a plant of *Victoria regia*.

For many years the aquatic gardens in Lincoln Park, Chicago, the Shaw Botanic Garden in St. Louis, Missouri, the New York Botanical Garden at the Bronx, and Prospect Park, Brooklyn, as well as in other cities, have paved the way for the advancement of this popular and most interesting phase of gardening.

But it was not until Latour-Marliac, of France, conceived the idea of crossing species of the hardy nymphaeas of the United States, notably the southern species *N. mexicana* (*N. flava*) and *N. tuberosa* (Fig. 3009, from G. F.), that a great impetus was aroused in the cultivation of water-lilies. The cost of maintaining a high temperature for the cultivation of the tropical lilies, besides the necessity of having a glass structure and water-tight tanks, cisterns, and so on, seemed still to impress the public generally that it was too costly to construct artificial pools and fountain basins. The products of Latour-Marliac found a ready market in England and as rapidly as he introduced a new hardy water-lily the more enthusiasm was aroused and the more the demand increased; and their popularity naturally spread to the United States. See also the discussion under *Nymphaea*.

It has been demonstrated that water-lilies can be grown successfully in the United States; not only the hardy varieties and the hybrids but the tender tropical nymphaeas, the victorias, the Egyptian and Japanese lotus are to be seen, during our summer season.

Many gardens and plantings of water-lilies and aquatic and subaquatic plants are too stiff and formal. Nothing is so inartistic as regular lines on the margins of some ponds and again of crowding too many varieties in one small pond. Natural planting is in masses and groups, and single plants are admissible only in small ponds or artificial basins in small and limited gardens.

Since it is found that reinforced concrete is the simplest means of construction and that water-tight and frost-proof receptacles can be secured at moderate expense, water-gardening is rapidly developing. Also the number of species has so rapidly increased that it is no longer difficult to select water-lilies for a miniature garden, tubs, small pools, fountain basins, ponds, and lakes; also for all seasons of the year, as it has been demonstrated that these charming flowers can be had in the depth of winter.

For the small garden where there is but a limited space, a miniature artificial stream terminating in a small pool could be constructed; on either side of this streamlet may be planted moisture-loving plants such as calamus, calthas, *Calla palustris*, rushes of various kinds, menyanthes, sagittarias, lobelias (cardinal flower), *Myosotis Scorpioides*, and iris in variety; and in the pool the miniature water-lily, *Nymphaea tetragona* (*N. pygmaea*) (white) and *Nymphaea tetragona helvola* (yellow). This style of water-garden can be carried out on a much larger scale where space will permit and a much larger collection of subaquatic and moisture-loving plants can be used as well as more nymphaeas and of larger dimensions.

Water-gardening on a small scale can be most successfully carried out with the use of tubs, half-barrels sunken in the ground, two, three or more placed as thought best. In the rear of the tubs plant Japanese iris, flags, and moisture-loving plants, making a pleasing background, and between the tubs if ground can be kept moist, parrot's feather (*Myriophyllum proserpinacoides*), or *Myosotis scorpioides* (*M. palustris*), or *Lysimachia nummularia*, or dwarf trailing plants. For tub culture nymphaeas of moderate growth are preferable. *N. Laydekeri* var. *rosea* and *N. Laydekeri* var. *lilacea* are both charming varieties of pink rosy lilac, changing to rose and carmine, very free flowering. There

3009. *Nymphaea tuberosa*, a native water-lily readily grown in ponds. The rootstock is shown in Fig. 2555 in Vol. IV. ($\times \frac{1}{4}$)

are several other nymphaeas of moderate growth and pleasing shades of color suitable for tub culture. Many persons make serious mistakes by selecting strong and vigorous plants suited only for large ponds or even lakes. The plants may live and be very thrifty but will not flower.

used in outdoor planting. The fibrous-rooted exotics, such as palms and tree ferns, are grown in greenhouses for the full year, either in permanent beds or in pots and tubs. The larger and more perfect the specimen, the greater its value. Usually in such a collection of plants under glass there are numerous species each

3010. The native fish-grass, *Cabomba caroliniana*; sometimes confused with *Myriophyllum*. ($\times \frac{1}{2}$)

A better and very satisfactory water-garden for a small place can be had by constructing a concrete pool 4 to 5 feet, or any size desired, bearing in mind that a large pool in a small garden is inconsistent. A pool or basin 4 to 5 feet in diameter and 2 feet deep will accommodate three nymphaeas. The surroundings may be similar as recommended for tubs, but no two gardens are alike.

Other aquatics may be found under the genera *Alisma*, *Aponogeton* (*Ouvirandra*), *Azolla*, *Brasenia*, *Butomus*, *Cabomba* (Fig. 3010), *Ceratopteris*, *Eichhornia*, *Elisma*, *Elodea*, *Euryale*, *Hottonia*, *Hydrilla*, *Hydrocharis*, *Hydrocleis*, *Lemna*, *Limnobium*, *Limnocharis*, *Ludwigia*, *Myriophyllum*, *Nelumbo*, *Nuphar*, *Nymphoides* (*Limnanthemum*), *Pistia*, *Potamogeton*, *Riccia*, *Ricciocarpus*, *Sagittaria*, *Salvinia*, *Utricularia*, *Vallisneria*. See also the articles, *Aquarium*, *Aquatics*, *Nymphaea*, *Victoria*; also *Bog-gardening*, page 2666.

WILLIAM TRICKER.

Subtropical-gardening.

Under this denomination are included all those gardening efforts that aim to introduce into cool or cold climates the plant forms and the foliar luxuriance of tropical and semi-tropical regions. The subtropical garden may be permanent if it is under glass; but the term is usually employed to denote the summer effects secured by transferring glasshouse plants to the open and combining them in such a way as to produce a harmonious composition. It is not often that an approach to real tropical effects can be made in a northern garden, and yet it is well to have these effects in mind; Figs. 3011, 3012, reduced from *Garden and Forest*, show real tropical vegetation.

Subtropical plants are represented by the lush-leaved caladiums and cannas, the brilliant-colored foliage of crotons and dracenas, the towering plumes of palms, the succulent leaf or stem of century plant or cactus, and the dense rank ground-cover of selaginellas and todeas. The interest in such plants is chiefly in the foliage, rather than in the flowers. In the plant groups they stand at the opposite extreme from the rock-garden plants with tufts, cushions, and mats of miniature foliage that in the blossoming season are nearly covered with flowers, and thin films of mosses, lichens, and algae on the rock and earth surface.

The subtropical plants of each of the climatic regions of the United States are usually from a warmer region, although natives having a like character may well be

represented by one or a few plants, all grouped together in a crowded mass. Such a collection is not a subtropical garden and does not represent the most effective use of the material.

The potted plants that have foliage tough enough to withstand summer winds and sun, such as palms, cycas, ficus, and crotons, are often used in the garden in summer, or under the protection of trees, as subtropical beds or garden compartments. Each plant is valued for itself, just as it is in the greenhouse in winter, size and perfection of form being its chief attractions. Each has no relation to the foliage about it, except that its unusual character of leaf and growth makes a striking contrast to the normal native vegetation. For this kind of planting a few well-grown specimens give the desired summer appearance to the garden.

One of the very best of indoor subtropical gardens in America is the tropical house at Garfield Park, Chicago, where a comparatively few species, such as the tree-fern overhead and selaginellas as a ground-cover, are used in large numbers to make bands of foliage to arch paths and hide the glass roof, and to frame in vistas to glimpses of water, with carpets of green below. Here is a consistent and exquisite example of subtropical-gardening, the dominant note is light with the artificial construction that supports and protects it all, so cleverly disguised as to make it appear like a real glade in the

3011. A tropical planting.—Entrance to the botanic garden, Peradenia, Ceylon.

tropics. There is an effect of airy lightness to it all that is a thrilling surprise as one passes in from the snows of winter out-of-doors. Equally as distinctive and effective results would be secured by the use of such greenhouse vines as *tacsonia*, *allamanda* and *bougainvillea*, or by the use of the somber greens of *ficus*.

In the open air, the use of palms, tree ferns, dracenas, crotons, caladiums, and *ficus* for summer decoration is not widespread. On large estates and in parks that can boast of greenhouses, a group planting of these subjects in the summer in the open is often to be found. In this case the outdoor use of the plants is more or less for the good of the plants and therefore little care or study is given to the grouping. The plants are "turned out to pasture" to rest up from the strenuous winter and stiffen their stems and roots for another year. Their winter appearance is their main purpose. Sometimes, especially in parks and botanic gardens, the plants are grouped by family or ecology, as a succulent group, desert group, or palm group, keeping closely to their winter arrangement under glass, more to put them under somewhat natural conditions for their best growth that they may require less personal attention from the gardener, than from a desire for any definite landscape effects.

The nearest approach in the United States (outside the very southernmost parts) to the tree-like palm vegetation of the tropics and subtropics is in the palmetto (Fig. 3013; also Fig. 3516, Vol. VI), which is native as far north as North Carolina, and is very useful as a decorative plant.

The smaller-growing subtropical plants are much used in the production of the most studied designs in planting, namely, in the construction of floral patterns, the very precise designs of city seals and the emblems of the many secret orders, "floral signs," and rarely, as in Regent Park, London, in the making of floral clocks. In these plantings, use is made of *celosias*, *alternantheras*, *coleus*, and *echeverias* and other tender succulents. This use of plants is decidedly on the wane on private estates and in the larger parks, for it has not now the sanction of fashion for the making of permanent seasonal garden features, but it has a value as display in horticultural or other exhibitions as a temporary affair, showing gardeners' ingenuity.

One great use of individual subtropical plants in pots has been in formal gardens as decorative adjuncts. These are then distinct garden features, garden accessories of rank similar to statuary and special flowerbeds. For such effects, large "orangeries" were maintained in the great day of the formal garden in Italy and France, and the use of such plants has been retained in our elaborate gardens today.

In park planting, the use of subtropical plants often produces pleasing pictures, but only when the entire

surroundings are very artificial and refined. Since the final character of a finished planting is based solely upon the foliage mass, plants of the same character only should be used in the separate plantings. The most natural effect is gained when the plants are grown in the ground, either with the pots plunged or planted directly in the soil. For this purpose the plants must be given conditions under glass to keep them alive all winter, but not necessarily in active growth, or kept in a dormant condition in pits, or stored as tubers. Plants for this purpose may be thus grouped—the taller woody plants to give height of green foliage to the group, low tender flowering herbs to give color from leaf or flower, and bulbous plants for bold leafage or bright flowers as fillers among the foliage plants.

Plantings of this kind involve considerable yearly cost for storage of potted plants or tubers, and great expense of annual planting and digging. Then there is a

comparatively short season of foliage and flowers, from the time that the semi-dormant vegetation gets under way in July until cut down by early frosts. Yet effects not otherwise to be secured by plant materials can be given gardens and parks in this way. This is a use of tender plants that will be greatly developed in the future, by park superintendents and owners of large estates who have the courage to break away from the usual specimen or jumbled planting, and make real garden pictures. There is very little of this kind of gardening as yet. The temporary tropical foliage of our summer gardens is much more effectively used today than it was a few years ago, but the problem must be studied more carefully before the best possible use is made of this material.

The ideal subtropical garden gives in a small compass the feeling of the wonder and luxu-

riance of the vegetation of the tropics, and suggests some of its pictures, whether under great glass roofs or in the open ground in the summer.

WARREN H. MANNING.

Plants for the seaside.

Very distinctive types of American scenery are to be found along our seashores. The very dark green mangrove thickets come to the salt-water's edge on the Florida and the Gulf coasts with a backing of savannas of tall grasses, fringes, and islands of palms, and gloomy thickets of cypress trees draped heavily with the hanging gray moss-like *tillandsias*. Farther north on the Atlantic coast are great hills and sweeps of sand-dunes, constantly shifting, overwhelming the stunted growth of pine, cedar, oak, and maple. Here the sand-reeds push out their long fingers of undergrowth and root-fibers to hold the sand in place, and they establish conditions for shrubs of huckleberry, rose, deciduous holly,

3012. A tropical growth.—Giant bamboo in the Botanic Garden of Ceylon. *Gigantochloa atter*.

baccharis, and iva, and give protection to the young forest trees. Along the rock-bound New England coast are wind-swept compact masses and distorted individuals of cedar, pitch and Norway pine, corresponding in a way to the similar Monterey pine and cypress of the Lower California shore. With the pines and oaks of New England are maple and shad-bush with ground-cover thickets of bayberry, rose, beach plum, huckleberry, and baccharis, and compact evergreen mats of bearberry, crowberry, and hanging curtains of the prostrate juniper over faces of ledges. In the salt-marshes are great patches of the rich green sedges, and in the flats the brilliantly colored samphires.

The main thing to be considered in the development of this native growth is to let it alone when it is well established. On the drifting sands of the dunes and plains of the seashore, plantations of the beach-grasses are made and protected as well as plantations of pines and shrubs. In California certain lupines and acacias have been successful, together with the reed, in holding the drifting sand.

There are two kinds of seaside planting: the adaptation of the usual species used in the lawn and garden to seashore conditions for effects like the usual refined planting; the other the planting for definite seaside effects by the almost exclusive use of typical maritime flora. This second kind of seashore planting is rarely attempted, as natural seaside pictures are hard to imitate. The problem as usually conceived is one of finding plants that will endure seaside conditions.

The tidal marshes are always fully planted by nature, and man can add little to good purpose. In sheltered bays, especially where the soil is good, the existing flora usually differs little from that common to the region inland, and it is no great problem to add to it. Even on the most exposed sites there is a low herbage and stunted undergrowth while a few picturesque wind-twisted trees give special distinction to the landscape. Even evergreen trees are often found near the shore-line, and the black spruce on the Maine coast, pitch pine and red cedar in southern New England, Jersey pines on the sand-barren coast of the middle states, and farther south bald cypress, until this gives way to the tropical palmetto and mangrove.

Given partial shelter near the taller woody plants, many low shrubs and herbs may be grown near the seacoast. There are many showy natives in the maritime flora and many more may be brought from Europe, though few have been tried as yet. The salt in the soil or water is rather a minor factor to many plants. More important to their welfare is the light sandy or heavy clay soil on the seashore above the tide-line. For the woody plants, the great factor is the high wind which stunts the branches and foliage. Though the winds are high, yet the temperature is more even and usually higher than at the same latitude inland. This is a favorable factor.

Since the sheltered nooks are not at all difficult to plant, it is on the exposed sites where the soil is poor that the problem is usually specially considered. If the soil is wet just above the tide-line, the beaches need no planting to hold the soil in place. When the soil is light and dry and shifts with the wind, not only is root-hold for the plants difficult, but the wind-driven sand cuts the twigs and foliage. It is here, where wind and wave meet, that several grasses do good work in holding the shifting sand in place until larger-growing plants can get a foothold. Two good sand-binders are the beach-grass (*Ammophila arenaria*) and sea lyme-grass (*Elymus arenarius*). These can be set out as small plants or the seeds sown upon the sand. Immediately branches or heavy straw should be thrown on to hold the sand for a time until the grass takes hold. When these tall grasses are established, they may be reinforced by lower tufted grasses, such as fescue and stipe.

Immediately back of this line of exposure should

begin the shelter-belt of trees and shrubs. This would consist of quick-growing trees, such as some of the willows, poplars, locusts, and some of the native cherries (*Prunus serotina*, *P. pennsylvanica*, *P. virginiana*, and the like). These are to be followed by more permanent material, such as the stiff thick-growing thorns and native crab-apples, and the species of oaks and other native forest trees that will live in light soil. Trees with large or compound foliage are to be avoided. Several coniferous evergreen trees thrive in conditions close to the salt-water, particularly the white spruce, pitch pine, red cedar, and their geographical relatives. A great many trees, even the sturdiest natives, cannot thrive under extreme conditions along the seashore.

Beneath the partial shelter of groups of trees, a great many shrubs will thrive under the handicap of sand and salt and wind. Particularly worthy of note are such common shrubs as *Baccharis halimifolia*, *Lycium halimifolium*, *Ligustrum vulgare*, *Shepherdia canadensis*, *Hippophaë rhamnoides*, *Salix viminalis*, *Rhamnus Frangula*, *Cornus paniculata*, *Rhus copallina*, and the like, and among the beach-grasses *Prunus pumila*, *P. maritima*, *Myrica carolinensis*, *Cytisus scoparius*, and the

species of *Tamarix*. To tie the shrubs together, several vines, as the native species of grapes, *Celastrus*, and *Smilax*, are very useful.

For details of color, masses of native or exotic perennial herbs may be grown. In dry soil select some of the species of *Armeria*, *Sedum*, *Lathyrus*, *Asclepias*, *Liatris*, *Silene*, *Statice*, *Opuntia*, and so on. In wet soil try the native species of *Hibiscus*, *Iris*, *Acorus*, *Thalictrum*, *Lythrum*, *Solidago*, and their

3013. The palmetto or sabal of the southeastern states.

near exotic relatives. The splash of salt-water is often fatal to many annuals; but those hardy annuals that like light warm soils, as portulaca and the Shirley poppy, will give masses of bright summer color. In the planting of herbs, there would be no special soil-preparation, or after-care, as refined garden effects are here out of place.

Three distinct purposes are served by a judicious seaside planting: shelter from strong winds to benefit the crops and man, checking of shore erosion and sand movement, and definite landscape effects. One should not so much strive to secure gardenesque effects but rather to intensify the natural features of the landscape.

Examples of successful seashore planting are numerous along the coast of New England where summer colonies of the wealthy have been established, parts of Long Island, and in many places along the coast of the Middle Atlantic states. The first work in seaside planting in this country was to prevent shore erosion, and from this work have developed the further uses for shelter and landscape effect. The problem of the shores of the Great Lakes is very similar, and much excellent

work has been undertaken along the shore of Lake Michigan, just north of Chicago. A consistent plan for the development of this particular shore has been advocated.

There are few books devoted wholly to the problem of seashore planting, and much experimenting is yet to be done. See "Seaside Planting of Trees and Shrubs," by Alfred Gaut (England) and "Gardens Near the Sea," by Alice Lounsberry. WARREN H. MANNING.

Succulent plants and their culture.

Succulents are fleshy plants of many kinds, but forming a cultural group well known as such to gardeners. They are grown mostly for their striking or grotesque usually condensed form, and not for the verdurous character of foliage and spray; and some of them are notable for their showy bloom.

This aggregation of plants is comprised of genera and species of several very remotely related families. Cactaceæ, perhaps, contains the largest number of genera and species belonging to this group, although not all members of the family are strictly succulent in

3014. A formal bedding design in succulents.

habit. Next in point of number is undoubtedly Amaryllidaceæ, represented by *Agave* and *Furcraea*, with *Euphorbiaceæ* as a close third, represented almost wholly by the great genus *Euphorbia*, although a few species of *Pedilanthus* are to be included. *Crassulaceæ* comprises a large number of genera and species, nearly all of which are succulent in habit of growth, although comparatively few genera are common in cultivation. Conspicuous among these crassulaceous things may be listed *Bryophyllum*, *Cotyledon*, *Crassula*, *Echeveria*, *Kalanchoë*, *Sedum*, and *Sempervivum*. In *Asclepiadaceæ* the group is represented chiefly by *Stapelia*, although, to a limited extent, one finds in cultivation representatives of *Caralluma*, *Ceropegia*, *Duvalia*, *Echidnopsis*, and *Heurnia*. *Bromeliaceæ* gives two genera, *Dyckia* and *Hechtia*. *Liliaceæ* contributes *Aloe*, *Apicra*, *Gasteria*, *Haworthia*, and a comparatively small number of species of *Yucca*. The great family of *Compositæ* has representatives in a section of the genus *Senecio*. By some authors this group of *senecios* is considered as having generic standing under the name *Kleinia*.

In their wild forms, succulents are native to widely separated geographical areas, for the most part being indigenous to the arid or semi-arid regions of Asia, Africa, North and South America, and the West Indies. They have this in common, however, that the climatic and soil conditions of these remote habitats are comparable and such as to induce just the characteristic growths that these plants exhibit. For this reason they are usually brought together, in cultivation, and given the same or very similar treatment.

The use of succulents.

Many of the succulents are very attractive and ornamental grown either as single specimens, in groups of one class, or when different genera and species are brought together in mixed planting. For the most part

the agaves are too large and bulky to be used to advantage other than as single specimens and a few species are not uncommonly employed in this way. Among these may be mentioned *Agave picta*, the variegated forms of *A. americana*, *A. atrovirens*, and *A. Milleri*. They are commonly grown in tubs to facilitate handling. Thus treated, they are housed in winter and in summer are placed in some favorable location on the lawn. Some of the best yuccas are hardy as far north as New England and the lake region. *Yucca filamentosa*, *Y. gloriosa*, and *Y. glauca* have received considerable attention. They are attractive as single specimens; in small groups on the lawn, or when used as border plants with a shrubbery background. In summer they produce large panicles of showy white waxy flowers which are very striking throughout the daytime and are especially so by twilight. The foliage being evergreen gives an added value to the plants for winter effects. A considerable number of this group of plants is well adapted for use in window-gardens. The very grotesqueness of some and the remarkable symmetry of others appeal to one's interest as much as do many gaudy and highly colored flowers of other classes of plants. Furthermore, a large proportion of these plants produce very excellent flowers, and frequently the resulting fruits are equally showy. Among the species valuable for individual pot-plants may be mentioned the following. Nearly all the *echeverias* are attractive in both foliage and flower characters. The globose and stemless rosette forms of *sempervivum*, commonly known as hen-and-chickens, are especially noteworthy. The production of numerous offsets and these appearing from beneath the foliage of the parent are very interesting and suggest the application of the common name.

A very large number of the smaller cacti deserve consideration. The crown of flowers, followed by a like crown of colored fruits, is particularly pleasing. The numerous species of *stapelias* are easily grown and in the autumn produce a variety of strikingly showy flowers. Their one objectionable feature is the disagreeable odor of the freshly opened flowers, but this passes away in a very short time, while the flowers remain open for several days.

Not all the succulents lend themselves well to ornamental planting, although many can be thus used and very pleasing effects are produced. The small globular and short cylindrical cacti, with their great diversity in color of the plant-body and of the spines, give material for very effective combinations in design work. They have this advantage over foliage plants used in such work, inasmuch as their growth is so slight that the plants may be placed close together at the beginning and, without any special subsequent care, the design thus formed will retain its full outline throughout the season. A suggestion of the possibility of using cacti in this way is to be seen in the accompanying illustration (Fig. 3014). For this class of planting *echeverias* are undoubtedly the best material obtainable. The individual plants are equally as symmetrical and pleasing as the cacti, and the range of color variations among the species is fully as great. They have the added advantage that they can be propagated more easily and more abundantly than is possible with cacti.

When a large number of mixed genera and species of succulents is available, exceptionally attractive plantings may be produced by a combination of these in more natural rather than formal designs. (Fig. 3015.) These appear to best advantage when planted among rocks and the soil surface covered over with gravel and sand. Such treatment not only gives a more natural appearance to the planting but is advantageous because it keeps the plant-bodies from coming in contact with

the earth, which to most of them is very injurious if the soil is wet for any considerable time. In northern climates these beds must necessarily be but temporary combinations, to receive the plants for the summer months. In the south and southwest regions, where most of the succulents are quite hardy, the planting may be made permanent. In such cases very pleas-

larger than a small pea. One of the chief drawbacks in growing cactus seedlings is their susceptibility to "damp off" in their younger stages. The protection afforded by this layer of gravel removes that danger. It also prevents any baking of the surface of the soil. The pots are then placed in a pan of water and allowed to remain until the water shows on the surface of the soil. Subsequent watering can be accomplished with a fine spray, applied to the surface of the gravel.

After planting, the seed-pots should be placed on a bench which is insulated in vessels of water or, better, in water with a surface coat of oil. This oil is to exclude ants, which have an especial liking for cactus seeds. Best results are secured in a humid atmosphere and a temperature of at least 70° F. The seedlings of most genera ought to appear within ten days, but *Opuntia* may require a little longer. When the seedlings begin to show spines, they may be transplanted into small flats of earth into which a little more humus or sod soil has been mixed. They may remain in these flats for one to several years, depending on the rapidity of growth in different species. Eventually they are

potted off as individual specimens or placed in the open ground.

It is only in the southwest states that many of the cactus plants are hardy enough to be permanently planted out-of-doors. Throughout the greater part of the United States they are tender and require greenhouse protection in winter. In this colder region they may be planted in the open ground of a conservatory, where they thrive excellently, or they may be kept in pots in winter and, in the hottest part of summer, be removed to the outside and the pots plunged in beds.

Almost any cactus will readily strike root from cuttings. The cut surface must be allowed to dry for several days, until a corky layer has formed over it. The cutting may then be placed in sand to root, its base but little below the surface. If slender, the cutting should be tied in position to a supporting stick.

Grafting of cacti is almost unlimited in its possibilities, although employed only in particular cases. Small globose forms, such as *Mammillaria* (Fig. 3016), *Echinocactus*, *Echinopsis*, and others, are frequently grafted on some abundantly rooting *Cereus*. Good stocks are provided by *Cereus Bonplandii* and *C. tortuosus*, though

3015. An informal planting of succulent subjects.

ing effects are produced by planting on a sloping surface, in more or less raised beds or, better still, in rockeries.

The cultivation of succulents.

For a general rule, it may be stated that all succulents require an open porous sandy soil and perfect drainage. Other conditions, such as watering and atmospheric humidity and temperature, must vary somewhat with individuals or with special groups. Nearly all the species are very easily grown from seed, although in many cases vegetative reproduction is more available. In fact, some species have natural adaptations for propagation in this way as well as by seeds, and quicker returns may be had from the vegetative methods. The method employed in propagating cacti from seed has given equally excellent results when applied to all other genera of succulents and is therefore given in all essential detail.

Cacti are especially easy to start from seeds and with proper care may be readily brought to maturity. Experience teaches that such plants are better adapted to greenhouse treatment than those brought in from their native wilds. The latter suffer from the shock of radically changed conditions. For a germinating vessel, nothing can be more convenient than a 3- or 4-inch pot. If not fresh from the pottery, this should be thoroughly sterilized. Sterilization can be accomplished by soaking and washing in a dilute solution of copper sulfate (blue vitriol) and subsequently rinsing well; or the pots may be placed in a furnace till all organic matter has been destroyed. This sterilization is necessary for the reason that the seedlings must remain in the seed-pot for a considerable time before it is possible to transplant them. If not sterilized, the pot is likely soon to be covered with algae or other organic growth and this, spreading over the surface of the soil, will quickly smother the young plants. For the same reason also, the soil should be thoroughly sterilized. This seeding soil should be very sandy with only sufficient humus mixed with it to furnish food for the young plant, of which a very little is sufficient. To insure perfect drainage, the pot is filled at least one-fourth full of broken bits of pots or charcoal, on top of which is placed the soil up to about $\frac{3}{4}$ inch from the top. This is jarred down lightly and the surface leveled. The seeds are then scattered evenly over the surface and firmed down with a flat-faced cylindrical block. Over the seeds is placed a layer, about $\frac{3}{8}$ inch deep, of fine gravel not

3016. A condensed cactus form.—*Mammillaria micromeris*. ($\times \frac{1}{2}$)

almost any of the smaller columnar forms may be used. With these cions and stocks, it is necessary only to make a smooth horizontal cut across each and place the two flat surfaces together. The cion is held in position by placing soft strings or raffia over it and tying the ends firmly about the stock or to sticks thrust into the earth. *Zygocactus* (the old *epiphyllum*), *Rhipsalis*, and

Aporocactus (or *Cereus*) *flagelliformis*, which are epiphytic species, do well when grafted on slender upright species of *cereus*, but are more commonly placed on *pereskia*. If *zygocactus* is used as a stock, cleft-grafting is usually employed; if *ripsalis*, either the cleft- or saddle-graft.

Cristate forms treated as cuttings usually develop normal-formed new growths, but when grafted will continue the cristate character.

Although it is possible for cacti to survive a long drought in nature, yet when grown in pots they are seriously injured if their roots remain dry for any considerable time. They should not be placed on benches over the heating-pipes, where the soil soon dries. It is desirable to have the soil cool and the air overhead warm and rather dry for all desert forms. Contrary to a prevalent opinion, they require water. This should be applied in sufficient quantity only to keep the soil moist. A saturated soil quickly induces a soft watery rot which is fatal to the plant. This is especially likely if the soil contains any organic matter that has not been thoroughly decomposed. A small amount of lime in the soil is desirable, and soil should never be sour. Perfect drainage is necessary at all times.

Many species of *cereus* and *phyllocactus* (now properly *epiphyllum*) climb over trees or rocks by means of aerial roots. These are indigenous to the more tropical regions and should be grown in a separate room from the desert forms, in one where the atmosphere can be kept at a higher degree of humidity. They should, also, be provided with suitable supports on which to climb. *Zygocactus*, *ripsalis*, and other epiphytic cacti, may be successfully grown in this same room, but suspended in baskets in the way in which orchids are treated.

Agaves and *furcraea*s, although readily grown from seeds, are more commonly propagated from suckers, or from the bulblets produced in abundance in the inflorescence of many species. For these plants a good soil is one of half sod and half sand. In nature they do not form deeply penetrating roots but widely spreading horizontal feeders. In pot or tub culture, the roots quickly reach the walls of the container and the plant very soon becomes pot-bound. Furthermore, if the container is allowed to remain dry for any time the roots are seriously injured thereby. When possible, it is better to plunge the pots or plant directly in open ground.

Euphorbias and *pedilanthuses* are best treated in every way as are the cacti. Their cultural methods differ but very little. While it is possible to grow them from cuttings, it is less easily accomplished than with cacti. The cut surface should be placed immediately in powdered charcoal to check the flow of milky sap. When the surface is thoroughly dry, the cutting may be rooted in finely broken charcoal or in sterilized sand. These plants are very susceptible to bacterial rot. Grafting is possible but difficult. It is sometimes employed to preserve a cristate growth of the cion.

Most genera of *Crassulaceae* are propagated more readily from seeds or from stem-cuttings. There are a few noteworthy exceptions, however. *Bryophyllum* can be more quickly and just as abundantly multiplied

by placing matured healthy leaves flat on wet sand and kept in a moist warm atmosphere. In a very short time tiny plants will appear in the notches about the margin of the leaf (Fig. 673, Vol. I). When of sufficient size these may be removed and potted as individual plants. In most species of *echeveria*, multiplication is best accomplished by carefully removing the healthy mature leaves and placing them on sand as with *bryophyllum*. The base of the leaf must not be injured, for it is from this point that the one or more young plantlets develop. The leaf-like bracts on the flowering stock of many species are very easily detached and propagate even more readily than the normal leaves. The above method is adapted to the acaulescent species of *echeveria*. With the caulescent species the rosette is cut from the top of the stem and treated as a cutting. The parent plant, thus pruned, will soon throw out a number of growths from the dormant lateral buds. As soon as these have formed rosettes of about an inch in diameter they, too, may be removed and will readily grow as cuttings.

Many *Crassulaceae*, and *echeverias* in particular, suffer severely from attacks on their roots and the base of the stem by nematodes. For this reason only clean fresh or sterilized soil should be used in growing them. The various genera and species may be grafted back and forth but no special advantage is to be gained by the process. It is also possible to hybridize between the genera and the species, and a number of interesting results have been secured. Some of the *echeveria* hybrids have proved to be valuable additions to the group used in design work or for bordering other beds.

Asclepiadaceae is most commonly represented in collections by the genus *Stapelia*. These plants fare excellently when given the treatment recommended for cacti. The chief difficulty in growing them, in the past, seems to have been their proneness to decay at the surface of the soil, especially in wintertime. This is easily prevented. See that the drainage is perfect and use porous sandy soil. Spread the roots out on the surface of the soil and cover not more than $\frac{1}{2}$ inch deep with more soil. Over this place an inch layer of gravel about

3017. An elongated cactus form.—*Lophocereus Schottii*.

3018. A garden scene in which topiary craft is a feature.

the size of peas. Their susceptibility to decay at the surface is comparable to the damping-off of seedlings. The mulch of gravel is invaluable in remedying both maladies. Keep the soil moist but never saturated, and do not permit the roots to become excessively dry. This treatment will insure good continuous healthy growth and, in autumn, a reward of many attractive flowers. The other genera require like treatment. Grafting of genera and species is easily effected but of no special cultural value. Owing to the highly specialized structure of the flower in *Asclepiadaceæ*, it has thus far been impossible to effect artificial pollination, although natural hybrids, through the agency of flies, are very common. This is especially true in *stapelias*. Bigeneric hybrids have been reported.

Dyckia and *hechtia* of the *Bromeliaceæ* and *yucca*, and the aloe group of the *Liliaceæ*, should receive the same treatment as agave. The species are more commonly propagated by seeds, and the hybrids by division and stem-cuttings or division of the crown. *Senecio* (*Kleinia*), of the *Compositæ*, may be propagated either by seeds or by cuttings. With them, also, grafting is possible.

C. H. THOMPSON.

Topiary planting and garden architecture.

Topiary work includes sheared hedges, pollarded trees, clipped individual shrubs, whether shaped into simple, rounded, or pointed form, or into more elaborate designs. It includes the trimming of masses of foliage into the form of birds, beasts, furniture, architecture, and other conceits. The more intricate designs are usually attempted in evergreen plants.—Garden architecture comprises all structural or architectural elements introduced into the landscape except the main buildings that are to serve the primary uses of a property. This definition thus includes all walls, trellages, posts, gates, pavilions, exedras, loggias, pergolas, shelters, fountains, bridges, seats, pavements; closely related with it are garden and lawn ornaments and furniture, such as statuary, vases, urns, dials, bird-fountains, lanterns, and the like. It includes the plain, the simple, and the rustic, as well as the more elaborate, ambitious, or ornate. Virtually all of the historical architectural styles are represented or suggested in the forms of garden architecture. For interesting illustrations and discussions of these subjects, the reader should consult Blomfield and Thomas, "The Formal Garden" (London), from which Figs. 3018 to 3023 are adapted. Compare, also, Fig. 3025. Fig. 3024 shows a common form of vase, used not so much for its architectural placing as for a receptacle in which to grow flowers.

Topiary and garden architecture, although distinct and separate, are nevertheless essentially related, both in origin and in use. Both have their inception in the virtually universal formality of all early landscape design, and historically and at the present day they frequently stand side by side as related elements of a design.

For many centuries gardening was conducted behind inclosing and protecting walls, a practice made necessary by the uncivilized conditions. In general, such inclosed gardens were rectangular or geometrically regular, and comparatively small. They existed in immediate proximity to the owner's dwelling or adjacent to the building. The necessity of conserving ground and of utilizing it most efficiently lead naturally to arrangement and planting in straight lines and rows. Utility having thus first determined a regular arrangement of plant-materials in close proximity to architecture, esthetic composition, in its turn, attracted the attention of more cultured man and formal design in landscape gradually evolved.

Both garden architecture and topiary are attributes of the formal in landscape design, which is determined

by lines, axes, and balance of parts. The inappropriate use of either results in inharmonious and bad design and constitutes an esthetic abuse.

The following plants are well adapted to topiary treatment:

NOTE: E means plants evergreen.

F means plant must be protected in climate of Boston.

S means plant is semi-evergreen.

- Acer campestre*.
- Acer platanoides* var. *globosum*.
- Berberis Thunbergii*.
- E—*Buxus japonica*.
- EP—*Buxus sempervirens*.
- Carpinus Betulus*.
- Carpinus Betulus* var. *globosa*.
- Catalpa bignonioides* var. *nana* (=C. *Bungei* in the trade but not the true C. *Bungei* from northern China). A dwarf variety of the southern *catalpa* often grafted high on upright stem.
- E—*Chamaecyparis nootkatensis*.
- E—*Chamaecyparis obtusa* var. *nana* (=Retinispora in the trade).
- Cornus mas*.
- Crataegus Oxycantha*.
- Evonymus alata*.
- E—*Evonymus radicans*.
- EP—*Ilex crenata*. (A small-leaved variety of this has grown in the Arnold Arboretum at Boston entirely unprotected.)
- E—*Ilex glabra*.
- Ligustrum Iboia*.
- Ligustrum Iboia* var. *Regelianum*.
- PS—*Ligustrum ovalifolium*.
- S—*Ligustrum vulgare*.
- E—*Picea excelsa*.
- E—*Picea orientalis*.
- E—*Pinus Cembra*.
- E—*Pinus densiflora* var. *pumila*.
- E—*Pinus montana*.
- E—*Pinus montana* var. *Mughus*.
- E—*Rhamnus cathartica*.
- E—*Taxus cuspidata*.
- E—*Taxus cuspidata* var. *brevifolia*.
- E—*Tsuga canadensis*.
- Viburnum Opulus* var. *nanum*.
- Viburnum prunifolium*.

In the growing of the plants for topiary use, no special care is required except to be sure that the plants are well grown in the nursery, vigorous, and naturally thick-topped and fine-twigged. If the piece

3019. A wall inclosure of topiary work.

is to be a hedge or continuous line, the plants should be very uniform in size and vigor when set and the ground should be prepared in uniform condition so that all the subjects will have equal chance. The plants should be set close together. Clipping should be begun soon after the plants are established to keep them close and to develop and preserve the side and lower branches; and the clipping should be practised several times each year. If the plants once overgrow, so that they become open and scraggly below, they can never be brought into good condition. Great care must be exercised to see that insects and disease do not get started, and that the plants suffer neither from drought nor wet feet and that they are well supplied with nourishment. See *Hedges*.

3020. Topiary walls and a dial.

Topiary work, as well as architecture, appears in gardens of many different ages. In fact, the whole history of gardens but emphasizes the continued use of formal foliage and architecture as essential elements in their design. As stated by Blomfield, "The word 'garden' itself means an enclosed space, a garth or yard surrounded by walls, as opposed to an unenclosed field or woods. The formal garden, with its insistence on strong bounding lines, is, strictly speaking, the only 'garden' . . . ; and it is not till the decay of architecture, which began in the middle of the eighteenth century, that any other method of dealing with a garden was entertained." The common use of hedges for the inclosing of gardens doubtless came into use when the more settled conditions made it unnecessary to retain masonry walls for protection.

In the writings of Pliny the Younger, who was born A. D. 62, is the most complete description of the Roman gardens. In a letter addressed to his friend Appolinaris, he describes the garden attached to his Tuscan villa: "In front of the Portico is a sort of Terrace, embellished with various figures, and bounded by a Box Hedge, from which you descend by an easy slope, adorned with the representation of divers animals in Box, answering alternately to each other; this is surrounded by a walk enclosed with tonsile evergreens, shaped into a variety of forms. Behind it is the Gestatio, laid out in the form of a Circus, ornamented in the middle with Box, cut into numberless different figures, together with a plantation of shrubs prevented by the shears from running up too high; the whole is fenced by a wall, covered with Box rising in different ranges to the top . . ." After describing several summer-houses he proceeds: "In front of these agreeable buildings is a spacious Hippodrome encompassed on every side by Plane Trees covered with Ivy. Beneath each Plane are planted Box Trees, and behind these, Bays which blend their shade with that of the Plane Trees. This plantation forms a straight boundary on each side of the Hippodrome. . . . Having passed through these winding allies, you enter a straight walk, which breaks out into a variety of others divided

off by box hedges. In one place you have a little meadow; in another the Box is cut into a thousand different forms; sometimes into letters expressing the name of the master; sometimes that of the artificer; whilst here and there little Obelisks rise intermixed alternately with fruit Trees; when on a sudden you are surprised with an imitation of the negligent beauties of rural Nature, in the center of which lies a spot surrounded with a knot of dwarf Plane Trees. Beyond these is a walk . . . where also Trees are cut into a variety of names and shapes. . . . At the upper end is an Alcove of white marble shaded with Vines, supported by four small Pillars of Corystian Marble. From this bench the water, gushing through several small pipes, falls into a stone Cistern beneath, from whence it is received into a fine polished Marble Basin, so artfully contrived, that it is always full without ever overflowing. . . . Corresponding to this is a fountain, which is incessantly emptying and filling; for the Water, which it throws up to a great height, falling back again into it, is, by means of two openings, returned as fast as it is received. Fronting the Alcove stands a Summer House of exquisite Marble, whose doors project into a green enclosure; as from its upper and lower windows the eye is presented with a variety of different Verdures. Next to this is a little private closet . . . Here also a fountain rises and instantly disappears; in different quarters are disposed several marble seats, which serve, as well as the Summer House, as so many reliefs when one is wearied by walking. Near each seat is a little fountain; and throughout the whole Hippodrome, several small Rills run murmuring along, wheresoever the hand of Art thought proper to conduct them, watering here and there spots of verdure, and in their progress refreshing the whole."

The Romans, establishing themselves in England, built gardens in which topiary work was doubtless to be found. Otherwise, in England prior to about the eleventh or twelfth centuries, gardening as an art of design and taste can scarcely be said to have existed. It is recorded, however, that in 1123 Henry the First formed a park at Woodstock, and it is the first of which authentic record has been preserved. It was probably intended chiefly as a game-preserve but contained, however, a labyrinth. And it is recorded as the custom of the times for the nobility to develop pleasure-gardens in the orchards beyond the walls of their castles, the chief embellishments of which consisted in "plants cut into monstrous figures, labyrinths, etc."

It is in the gardens of England of the early Renaissance periods and shortly before this time that the most extensive use of topiary work is found, in the greatest variety and elaboration of form. Topiary art was practised, however, in all European countries for centuries. It has been given particular and peculiar expression in each of several countries. The Dutch developed the art of carving in verdure at an early date and many strange and curious forms in box, along with many rare and flowering plants,

3021. A bit of topiary craft.

were introduced into England from Holland. In France and Italy it was not so much a large variety of elaborate and intricate topiary as an extensive use of the simpler forms of clipped foliage as a means of gaining effect in larger, more monumental, and pretentious landscape arrangements than were elsewhere undertaken. The architectural gardens of the Italian Renaissance exemplify the effective and appropriate use of architecture in the garden. Here trees, naturally formal in habit, are combined with sheared hedges and edgings. These wonderful gardens teach the remarkable effectiveness

of such method in design when executed by the master hand.

The designers of the tremendous and monumental landscape arrangements executed in France in the later Renaissance periods gained distinctive effects by the very bold use of sheared foliage; they virtually carved

3022. An attractive dial.

their broad axially related plans out of the woodland. The "Bosque" in French design is comparable to the "Topiary grotesque" in the English. The French parterre gardens, in which intricate and elaborate geometrical designs are worked out in low sheared foliage or bed edging and white or colored gravel, are another expression developing from the same original motive as produced the topiary bird.

In the colonial gardens in America topiary work was common, mostly in the simpler form of clipped hedges, generally of box, and boxed parterre gardens.

Remains of many of these old gardens are still to be found in the Atlantic states, and a few old gardens are still in a good state of preservation and cultivation. The box-garden at Mount Vernon is perhaps the most noted, and is in an excellently preserved and restored state at the present time. See Plate XLVI, Vol. III.

A moderate amount of interesting and good topiary work is under way in gardens in this country today, and a few nurserymen are in position to furnish good clipped specimens in a variety of designs. The use of topiary work other than simple clipped hedges should be carefully and advisedly undertaken, however, for it is appropriate only when the whole architectural style of a property makes it suitable and when it becomes an inherent part of the scheme as a whole.

Garden architecture.

Any structure or structural element placed out-of-doors in nature takes on the significance of architecture, and must bear judgment as such. Landscape as such is either nature's work or man's work with nature's materials in their natural form. The placing of architecture in the landscape is always the combining of the obviously artificial with the natural, and the two must be brought into harmony. It is a deplorable fact that when, with the exercise of judgment and good taste, it is possible to attain harmony in the least costly as well as in the most expensive, so much bad and inharmonious architecture encumbers the landscape.

Under any circumstances, architecture becomes to some extent a feature of accent in the landscape, at least within its immediate surroundings. It is emphatic in contrast with its setting and always functions as focalizing the composition of which it forms a part.

In general, it is wiser to attempt a simple design and insure its substantial construction than to undertake the ornate in garden architecture. There is a world of interesting precedent in simple designs for the many smaller architectural embellishments of the garden, such as summer-houses or pools, pavements, seats, dial-bases, boxes, tubs, jars, and other ornaments and accessories. The use of simple boxes or ordinary pots

for flowers and specimen plants is to be encouraged, and the conversion of such inappropriate materials as plumbing fixtures into garden ornaments is to be condemned. The usual cast-iron vases and the like are marks of a passing era of bad taste. In lawn pottery, in the form of pots and vases, excellent designs are now to be had, as also of sun-dials.

No one consideration is more important than that the architectural style of even the simplest seat or sun-dial be similar to that found in the larger architecture of the building or buildings to which the landscape development may be related.

A number of reputable firms now produce substantially made garden furniture in considerable variety of good designs and in many different materials. Particularly good garden seats and garden pottery are now obtainable at reasonable prices and may be found in shops in some of the larger cities. The advertisements and trade catalogues of the manufacturing concerns are interesting and instructive.

However, the obtaining of individually well-designed and substantial articles having been assured, there remains still the selection of appropriate patterns. Garden architecture should correspond to the style, architectural and otherwise, of a property as a whole. Its appropriate use is its justification.

Rustic work is fitting and often most appropriate in a naturalistic setting. It is, however, architecture and should be so designed as to bear analysis as such. It should be structural in its line, and substantial. It is best when simple and unobtrusive in design. It is seldom appropriate when fantastic or whimsical. The occasional use of rustic work in such way that in its rough character it appears almost to have grown up with the surrounding wild conditions is very pleasing, particularly good unobtrusive seats, bridges, and shelters.

EUGENE D. MONTILLON

Planting for winter effect.

Winter is the season when there is the least sunshine, and the least sign of life and color in vegetation. As a floral festival, Christmas ranks second to Easter, owing doubtless to the relative scarcity and higher cost of materials. The ideal is for every family to grow its own flowers for Christmas gifts, but most persons have to content themselves with less personal products purchased from the florist. Holly is the symbol of Christmas as

3023. Vase at Hampton Court.

3024. Stone flower vase 4 or 5 feet high, used as a plant basket.

the lily is of Easter, each exemplifying the dominant color of the season. The popular demand in winter is for signs of hope and courage—hence the red berry, flower, or ribbon.

The phrase "winter-garden" has been used for a great variety of projects, indoors and out, ranging from the metropolitan restaurant with a few bay trees in tubs, to a winter home in Florida where one may work outdoors every day and all day. Notable progress has been made along many lines since 1900 in the art of living the year round amid beautiful vegetation.

Indoor winter-gardens.

Perhaps the oldest use of the phrase winter-garden refers to a type of unheated or little-heated greenhouse which was popular in England when plants from the Cape and Australia were fashionable, but was generally a museum of potted plants rather than a garden. A new stage began in America about 1905, when Mrs. J. W. Stewart, of Glen Ridge, New Jersey, made a real garden under glass. (C. L. A. 13:168-70.) It has a broad lawn to tread upon, instead of narrow concrete walks, and in place of potted plants raised in tiers for show, there is a continuous border 3 to 4 feet wide, with bulbs and other flowers growing out of the earth at the familiar garden level. The temperature is that of a living-room. Another new stage began in 1906 when the conservatories in Garfield Park, Chicago, were completed. These were not the first attempts at landscape gardening under glass on a large scale, but they are believed to be the most impressive series of indoor nature-pictures in the world. Portable greenhouses and window-gardens now make it possible even for renters to have something more than a few potted plants on the window-sill. Those who can afford no glass may at least force twigs in water, preferring the early bloomers, like peach, plum, and forsythia to the late bloomers, like lilac and dogwood. In this line, the most notable achievement, of late, is the forcing of stems 6 to 8 feet high, by keeping them in a slightly heated attic until wanted for the living-room.

Outdoor winter-gardens.

The southern states have a winter climate that makes outdoor work pleasant, and a landscape rich in types of beauty, as evergreen magnolias, long-leaved pines, and winter roses. Southern winter-gardens have their problems, but they can receive less notice here than the more acute problems of northern climates. A country with an evergreen grass, like Ireland, has a great advantage over America for winter beauty. English children are well protected from bitter winds by the omnipresent walled-garden or high-hedged home grounds. The formal winter-garden of England is often merely a

straight walk, between high walls of clipped yew. Wordsworth's winter-garden is an early example of the naturalistic winter-garden, i. e., a sheltered spot surrounded by informal masses of trees and shrubs noted for their winter attractions.

In the northern states, however, it is neither safe nor pleasant to garden out-of-doors every day, and the winter landscape is commonly bleak, ugly, bare, or commonplace. Our most pressing problem, usually, is shelter from winds. On the plains and prairies many homes are surrounded by shelter-belts, but the landscape effect is not the best, owing to the artificial outlines of the farmsteads, the ill-concealed barnyards, and the inferior species used—soft maple, box elder, Norway spruce. Windbreaks in straight lines, protecting orchards or stock, sometimes give a spirited army-like effect, but may become monotonous in a country where everything seems to be rectangular. In the East naturalistic shelter-belts are commoner. The practice of moving large evergreens with a half-frozen ball has developed notably since 1900, and full-grown evergreen hedges can be secured to shelter winter playgrounds.

Most persons see little beauty in the northern winter landscape. It is true that the East has little brilliant color or living green compared with England, China, or Japan, while the prairies and great plains have still less. Nature-study, however, opens the eyes of the people to a new world of beauty in outline and structure of trees, their trunks, and winter buds. The universal instinct for bright color, however, ought also to be gratified, and every family can receive and give satisfaction by means of foundation planting. Unfortunately, New York and Philadelphia may not have monumental evergreens to the extent that every London yard has box and holly, aucuba and veronica, yet many eastern homes may have mountain laurel on the sunny sides and rhododendron on the shady sides. Among the conifers most persons prefer the brilliant quick-growing but short-lived Japan cypresses, while lovers of permanence are willing to wait for Canadian and Japanese yew, Mugho pine, and Canadian juniper. Two superb evergreen vines, European ivy and evergreen bittersweet (*Evonymus radicans* var. *vegeta*), enliven house walls of brick and stone. On sunny days the red branches of Siberian dogwood are a cheery sight. Among the shrubs with brightly colored berries, the favorite for foundation planting is the Japanese barberry, largely because its red fruits are attractive all winter.

Types of winter-gardens.

Evergreen winter-gardens.—Perhaps the oldest type of winter-garden is the pinetum, which is primarily a collection of evergreens, but is also full of beauty during the period when other trees are leafless. One example is the Hunnewell collection at Wellesley, Massachusetts, part of which is doubled in beauty by reflection in a lake. Another example is the conifer valley in the Arnold Arboretum, which has a brook meandering through the center, while the heights are crowned by trees, the cultivated specimens on one side being balanced

3026. A good winter form.—One of the retinisporas.

3025. A winter-garden, presenting evergreen forms in tree, bush, and box borders.

by a noble hemlock forest on the other. In the pinetum at Highland Park, Rochester, New York, the walk runs through the grassy center of the valley, with dwarf evergreens ascending the banks, these being disposed at convenient levels and distances for the eye, so that the different textures may be enjoyed to the full. The

apparent height of this shallow valley is increased by planting the ridges with the tallest evergreens.

Shrubby winter-gardens.—Every arboretum or botanical garden is likely to have a fruticetum, or collection of shrubs. A garden composed almost exclusively of shrubs is attractive throughout the growing season, as well as during winter. There is a naturalistic winter-garden at Llyndanwalt, Abington, Pennsylvania, where a wood

3029. Attractive winter objects.—Cones of white pine.

of about an acre near the house has been provided with features of year-round interest, including a rhododendron collection, a dense underplanting of young hemlocks, and a border of shrubbery selected with special reference to winter beauty. From the outside, these shrubs give privacy, shelter, and color in delightful contrast to the ordinary wooded pasture, which is rather colorless. From the interior these shrubs animate the trails and enliven the outlooks that have been purposely left toward the best features of the landscape.

Skating-ponds.—It is now the fashion to border skating-ponds with shrubs that have brightly colored twigs. On sunny days these furnish bold masses of color that harmonize with the vigorous mood and gay costumes of the skaters. After providing for the casino and for the snow that must be removed from the ice, there is generally ample room for a collection of showy dogwoods, willows, and wild roses. At Rochester, New York, is a charming example, the shrubs being allowed to interlace like an old woodland border, so that the color of the twigs steals upon one unconsciously.

Gardenesque effects.—That it is possible to spoil even a winter landscape by overdoing color has been much demonstrated recently in parks, where nurserymen and gardeners have been allowed to plant large masses of Siberian dogwood and salmon-barked willow, the brightest of all winter reds. Such swamp-type plants are particularly inappropriate and gaudy on hilltops. A more poetic effect is produced by the "sunset willow" of the prairie states, a species of uncertain botanical status known to collectors as *Salix longifolia*. It is common along middle-western streams. The most brilliant but least tasteful effects produced with shrubs that have brightly colored bark are in reality the carpet-bedding system. The willows and dogwoods are cut to the ground every year or two, in order to produce the greatest number of showy shoots, which are kept at a height of about 3 feet. This system sacrifices height, habit, and dignity to display. A standard park effect is white pine bordered by Siberian dogwood, which is about the strongest contrast that is in good taste on lawns. Perhaps the strongest contrast furnished by nature in the North is hemlock and canoe birch.

Winter walks.—The cheapest and most practical winter-garden for the largest number, may be a simple walk leading to the front, back, or side door, bordered by shrubs and trees, of which half or more have winter attractions. Brick set on concrete is considered pleasanter to the eye and foot than concrete, and is drier

than grass. The tapestry type of brick set on edge is expensive, but gives a rich texture.

Materials for winter-gardening.

One hundred and twenty-eight trees and shrubs that have pronounced winter beauty were listed by John Dunbar from the Rochester parks, not including the evergreens or plants that lose their vivid color before the end of the holidays. With such a wealth of material there should be little excuse for bare and ugly surroundings. Only the classes of materials may be mentioned and exemplified here.

Broad-leaved evergreens.—These are often more expensive than the narrow-leaved evergreens, and of smaller stature, but they have more ample foliage and frequently showier flowers or fruits. All require special care. Examples are American holly, mountain laurel, *Rhododendron catawbiense* and *R. maximum*, evergreen thorn, trailing myrtle, evergreen bitter-sweet, box, and its substitute, *Ilex crenata* var. *microphylla*. The English standard of beauty is European holly, laurel, and hybrid rhododendrons, because the darkest and shiniest foliage is commonly thought to be more beautiful than the duller and yellow-green type. A more practical standard for our climate is furnished by American holly, laurel, and rhododendron. In nurseries where both classes of plants may be observed, the European kinds are unquestionably rich and aristocratic, but sound a foreign note, while the native kinds have a cheery, sunny color that is eloquent of adaptation to our climate and

3028. A good subject in the winter-garden.—Fruits of the barberry.

scenery. The same principle applies to the narrow-leaved evergreens, Irish yew being commonly but mistakenly preferred to Canadian or Japanese yew. Semi-evergreens, like

Hall's honeysuckle, are listed in this work under *Autumn-Gardening*.

Narrow-leaved evergreens.—The European standards are Scotch and Austrian pine, Norway spruce, silver fir, Irish juniper, and Irish yew. These are climatic misfits in America and constitute the bulk of the evergreen planting east of the Rockies that proves unsatisfactory. The American standards are white pine, hemlock, Douglas spruce, concolor fir, red cedar, and Canadian yew. The types of beauty represented in the two lists are not closely comparable.

Deciduous trees and shrubs.—Though lacking in brilliant color, the following are standards of quiet beauty.

Marked for their outline or habit are pin oak, sweet gum, white birch, pepperidge, sassafras, tulip tree, white oak, and sycamore. Noted for their winter buds are flowering dogwood, beech, shagbark, balm of Gilead, honey locust, swamp bay, sassafras, and pussy willow. Familiar by their trunks are beech, birch, shagbark, sycamore, white oak, tulip tree, sweet gum, flowering dogwood, and mountain-ash.

Shrubs with brightly colored berries.—These materials do more to transform ordinary city lots than any others here mentioned. Shrubs cost less than evergreens,

3029. A graceful winter form in dwarf juniper.

nature more quickly than trees, are fairly permanent, and are cheap. Of the shrubs with decorative fruits, there are two main groups based on duration. Those which are attractive all winter, like barberries, must be reckoned more valuable than those which drop by New Year's or cease to be attractive then, like snowberry and Indian currant. Each of these groups may be divided again on a basis of color. Red is the favorite color, because it seems to give the most warmth at the time it is most needed. Consequently the most popular shrubs for winter berries are the common and Japanese barberries, the multiflora and prairie roses, and the high-bush cranberry, all of which retain their red berries until spring. Of the other red berries, *Viburnum dilatatum* lasts until April; Japanese bitter-sweet until March; *Viburnum Sargentii* until February; while the following are attractive until February: Most species of *Evonymus* and *Cotoneaster*, *Ilex verticillata*, and red chokeberry (*Aronia arbutifolia*). The red-berried species tend to produce yellow varieties, but they have less popular appeal. Blue-berries of great beauty are borne by the familiar white fringe and the little known symplocos. Theoretically black is an unattractive color, yet practically the black fruits appear well, especially against the snow, the most familiar example being the massive cluster of California privet, while the open cluster of Regel's privet has more grace. *Viburnums* furnish many dark berries, as do the following choice plants: *Acanthopanax sessiliflorus*, *Rhamnus carthartica*, *rhodotypos*, *Phellodendron amurense*, *Rhamnus dahurica*, and *Aronia melanocarpa*. Theoretically white should be the chilliest and least attractive color in winter, yet the snowberry is probably the only bush that is planted almost wholly for its winter berries, and its popularity continues although it often loses its attractiveness before Thanksgiving. The small waxy berries of candleberry (*Myrica*) are an agreeable sight till January, but this plant is more famous for its fragrance.

Shrubs with brightly colored twigs.—These materials are even more brilliant than shrubs with brightly colored berries. The ordinary 2- to 3-foot bush of barberry has few berries, when planted in the fall, while a Siberian dogwood of the same size is a consistent mass of red from planting day in October until April. These materials are showier on sunny days than clouded ones, and look best when the sun is at one's back. They do

tolerably in the smallest yards of large and smoky cities but do not develop the brightest colors in dense shade.

In this group, also, red is the favorite color, the most popular being Siberian dogwood, with the Britzensis willow a fair second, the latter being unsuitable for foundation planting. Vivid color is often confined to twigs or wood a year or two old, as in the lindens, but a four-year-old Siberian dogwood is showy from the ground up. Those who like a change from the Siberian sometimes plant the silky dogwood, which has purplish red wood, or the quieter-toned stolonifera, but the latter needs a moist situation and is too scaly for foundation planting. Yellow branches are more popular than yellow berries. Willows furnish half a dozen yellow kinds, dogwood two good ones, and yellow poplar one. Vivid green wood is furnished by *kerria*, *Forsythia viridissima*, sassafras, *Cotutea arborescens*, and a variety of *Cornus sanguinea*.

Winter flowers.—The only hardy winter flower of importance is the Christmas rose (*Helleborus niger*), which blossoms in the North amid or under the snow any time from November to March. Winter crocuses are merely a coldframe hobby for enthusiasts. Scillas and the other March-blooming bulbs are often seen blooming in the snow, but they are essentially spring flowers. A unique and wonderful winter beauty is *Pieris floribunda*, which seems to be crowned by white flowers, but these are really buds. They are all the more wonderful because naked, and all the more beautiful because set off by evergreen foliage.

WILHELM MILLER.

Planting on walls. (Fig. 3030.)

Wall-gardening and walled gardens are two different departments of horticulture. The walled garden is an old English development based on the need of protecting fruit from thieves and on the fact that grapes and peaches do not ripen in the cool summers of England without extra heat, such as a south wall gathers. Out of these conditions have grown high brick and stone walls aggregating hundreds of miles in extent and forming a familiar sight in the English landscape. The walls have come to be covered with all sorts of fancy fruits trained like vines. They also shelter many subtropical shrubs trained as climbers, which otherwise could be grown only under glass. Although these walls are often crowned with broken glass or spikes, they are generally beautiful in themselves, or are made so by a clothing of vines. Moreover, earth-filled holes are often purposely left on top for the growing of rock-loving flowers, such as wallflowers, snapdragons, wall pepper, Kenilworth ivy, houseleeks, and wild pinks. Time adds the crown-

3030. Piece of a wall-garden.

ing touch of loveliness by encouraging mosses on the shady side and lichens on the sunny. This type of garden is not common in America because it is very costly to make and also to maintain, owing to the higher cost of skilled labor for training fruits. Moreover, a wall is not necessary in our own hot summer climate for the ripening of grapes and peaches. However, the walled garden will gradually increase in numbers, for several reasons: It offers better protection from thieves than hedges or shrubbery; it makes a kitchen-garden yield from one to three months longer by giving protection from cutting winds and frost; it makes a sheltered outdoor playground for children in winter; it makes an effective background for hardy perennial flowers; and it gives privacy and charm, which gardens open to every eye do not possess.

Wall-gardening, on the other hand, is a modern application, growing out of the English passion for alpine flowers and based largely upon the fact that many of these exquisite flowers perish in the hardy borders, because of the wet English winters, but flourish permanently in the chinks of a wall, where they get better drainage. This is true of wallflowers and snapdragons, which have glorified many ruins for centuries, while on the level ground they are short-lived. Thus, dry-walling became fashionable at the beginning of the twentieth century. It was customary, whenever grading operations left a bank of earth, to put in a retaining wall, avoiding cement, and laying alpine plants between the stones. The popularity of this type of garden is attested by Gertrude Jekyll's "Wall- and Water-Gardens," which has thirty-three plates illustrating the construction and main floral effects. Steps are commonly made in such a way that nearly all parts not actually needed for treading are filled with carpets and cushions of rock-loving flowers.

In America, wall-gardening was welcomed as an opportunity to replace some of the artificial, monotonous, and ill-kept grass-banks by retaining-walls clothed with the natural and varied beauty of flowers. Unfortunately, much of the most refined beauty of English wall-gardens, such as the mossy saxifrages give, is impossible here, because the hot summers are unfavorable to the choicer alpine. Analysis of the four largest and most successful examples of wall-gardening known in America in 1914 shows that great and new beauty has been achieved in this way, but that the largest floral effects are made by plants that are not particularly associated with mountains or rocks and which are easy to grow in ordinary gardens without the expense of dry-walling. Such desert plants as the houseleeks and stonecrops spread over large areas. Other successes are rock cress (*Arabis albidia*), woolly chickweed (*Cerastium tomentosum*), snow-in-summer, woodruff, wild pinks, alpine forget-me-nots, Kenilworth ivy, and veronicas. Such carpets, however, do not have the charm of the dainty rosettes and mossy cushions of the high-altitude alpine, such as saxifrages, primroses, gentians, and edelweiss.

It is possible to have some of these finer things, if one does not stuff the walls with too much earth. This practice, which seems reasonable to every beginner, encourages the plants to make roots within the walls, and such roots are naturally destroyed by the first hot weather. It is better to give them a little grit and only a pinch of earth, so as to force the plants to send long roots through the walls into the earth banks where they will find the moisture, coolness, and drainage that are demanded by high alpine.

Steps have been successfully filled in America with chink-loving flowers, but most gardeners are conservative about experimenting, declaring that the colder winters of America will cause damage to stone and flowers by the heaving action of frost. It is certainly unwise to have wide spaces between stones filled with material that will expand too much, but the aim should

be to give the plants as little root-room and food as possible in order to encourage their rooting outside the stonework.

WILHELM MILLER.

Screen-planting.

From the landscape architect's point of view, screen-planting may be used to hide unsightly objects, to afford protection from prevalent winds, to give a background to the house, to lend an air of privacy and seclusion, or sometimes to add an ornamental feature. It may take the form of deep border planting, narrow hedge lines or mere vine-covered screens. Trees, shrubs, and vines are all available; but, whatever is used, the denser its habit of growth, the better screen it will make. Other things being equal, evergreens are better than deciduous plants, for the latter lose their leaves in winter. However, if evergreens are not available, there are still many deciduous plants whose dense habit of growth make a good screen even after the leaves are gone. A border planting, as in Fig. 2999, is really a screen against objects beyond: so also are such cover-plantings as those in Figs. 3000, 3001, 3031 and others. The real screens, however, are those plantings made for this particular purpose, mostly narrow in form but dense.

3031. A screen subject in a corner.

Vines for screen-planting.

For brick, stone, tree-trunks, or other solid surfaces.

Deciduous:

Hydrangea petiolaris (climbs by root-like holdfasts).

Parthenocissus quinquefolia var. *Engelmannii*. A variety of Virginia creeper with disks, or suckers, on the ends of the tendrils, which enable the plant to fasten itself to a surface.

Parthenocissus tricuspidata var. *Veitchii*.

Evergreen:

Evonymus radicans var. *vegeta* (climbs by root-like holdfasts).

Hedera helix. Somewhat tender; in the N. should be planted where it will be shaded from winter sun or at least have its roots thoroughly mulched and the ground shaded by low growth about its base; climbs by root-like holdfasts.

Rapid-growing vines for banks or unsightly objects.

Annuals:

Boussingaultia baselloides. Twining tender perennial treated as an annual, growing from 10 to 15 feet a season; roots must be taken up and stored away from frost.

Calonyction aculeatum (twining).

Echinocystis lobata (self-seeding; tendrils).

Humulus japonicus (twining).

Ipomoea purpurea (twining).

Phaseolus multiflorus (tendrils).

Herbaceous perennials (dying down to the ground but springing up again from the root):

Ipomoea pandurata (twining). This and next have fleshy roots and may become a nuisance if allowed to spread.

Pueraria hirsuta. This is known also in commerce as *Dolichos japonicus*; grows 40 feet in a season; twining.

Woody perennials (woody stem persisting above ground).

Actinidia arguta (twining).

Aristolochia macrophylla (A. Siphon) (twining).

Celastrus scandens (twining).

Lonicera japonica var. *Halliana* (twining).

Lycium chinense and *L. hallimifolium*. Both are shrubs with recurring trailing stems which do not twine. Plant must be fastened to its support. Excellent to hold banks, but very vigorous and may become a nuisance.

Tall-growing vines reaching eaves of the house.

Actinidia arguta (vigorous; dark glossy foliage twining).
Aristolochia macrophylla. Twining; large heavy foliage; should not be used unless dense shade is desired.
Campsis radicans. This is a heavy vine climbing by root-like holdfasts which are too weak to hold it in storm or wind; must be fastened to its support. Somewhat tender in the N. and usually has more or less dead wood. Better when used as porch or pillar vine where it can be reached and pruned easily.
Celastrus scandens (twining).
Parthenocissus. All kinds; tendrils with or without disks.
Wisteria chinensis. The finest of tall-growing vines; vigorous and hardy at all times.

Vines for foliage only. All in the following list are deciduous, i. e., drop their leaves in winter. The only evergreen vines which can be used in the North are *Evonymus radicans* and *Hedera helix*. Even the foliage of *Evonymus radicans* will occasionally burn in winter although it is harder than English ivy in this respect. *Vinca minor* and *Pachysandra terminalis* are good creeping plants for evergreen ground-cover and Hall's honeysuckle is semi-evergreen, holding good foliage until Christmas. Other flowering vines also good in foliage are *Clematis paniculata*, *Forsythia suspensa*, which is a shrub with recurving and trailing stems excellent for running over a bank or hanging down a wall, *Rosa Wichuraiana* and some of its many hybrids, and *Wisteria chinensis*.

Actinidia arguta.
Akebia quinata. Very graceful vine with delicate five-parted foliage, semi-evergreen, remaining until January; twining.
Aristolochia macrophylla.
Celastrus scandens (berries red and orange all winter; twining).
Lycium halimifolium.
Parthenocissus quinquefolia. Beautiful red autumn color; first vine to color in the fall; climbs by tendrils usually without disks except in var. *Engelmannii*.
Parthenocissus tricuspidata var. *Veitchii* (beautiful autumn color; climbs by tendrils ending in disks).
Smilax rotundifolia. A vigorous wild vine with thick glossy foliage enduring both shade and wet soil.
Vitis Coignetiae. From Japan; a vigorous grower with immense leathery leaves usually brown felt beneath; the foliage is especially strong and bold and turns a rich red color in fall.

Vines for flower. Plants marked with an asterisk (*) have attractive foliage as well as bloom.

Campsis radicans. A heavy vine.
Clematis Jackmanii. Climbs by twisting leaf-stems. Flowers large and purple. *C. Jackmanii* var. *alba* is similar, but the flowers are creamy white. Both of these are good vines for bloom in July and August.
 **Clematis paniculata*. Climbs as does the preceding species. Flowers small and white, covering plant with a mass of bloom in September and October. Foliage remains glossy green, good until December. The best fall-blooming vine.
 **Forsythia suspensa*. Flowers yellow, appearing before the leaves, covering the plant with a mass of bloom in April. Flower-buds often killed by cold in the northern tier of states.
Lonicera Heckrottii. Climbs by twining. This is a hybrid which blooms continuously during July, August, and September. The flowers are rose outside and yellow inside, and as open and closed flowers are present at the same time they make a very handsome showing. The only objection to the plant is that it is badly infested with aphids or green-flies.
 **Lonicera japonica* var. *Halliana*. Bloom profuse and fragrant; flowers white, fading yellow in June and July.
 Rambler roses, in order of bloom, June and July. These must be tied up, but are hardy without protection except possibly in the northern tier of states. In such cold places one must be content with the upright shrubby *Rosa rugosa* in white, and red varieties, both single and double, beginning in early June; with the white *Rosa multiflora*, beginning from middle to late June; and with the pink *Prairie*, or *Michigan*, rose (*Rosa setigera*) which does not begin until the second week in July. *R. multiflora* and *R. setigera* are both shrubs with an arching habit and have produced many Rambler roses. Of the varieties following, those marked with a dagger (†) are the best: †*Fausendschön*, middle June, double, delicate pink, larger than *Dorothy Perkins*; *Lady Duncan*, single, rich salmon-pink; †*Excelsa*, late June, or early July, a long-season rose, double, rich crimson, a new variety, blooming at the same season as the old *Crimson Rambler*, but a better color; *Dorothy Perkins*, early July, double pink; white *Dorothy Perkins*, a white variety of the preceding; *Alberic Barbier*, middle July, semi-double or double creamy white, yellow in center, dark yellow in bud, excellent glossy foliage; *Aviator Bleriot* is a new variety, very similar to *Alberic Barbier*; †*Hiawatha*, middle July, a long-season rose, single, bright red with white center and yellow stamens; **Mrs. H. M. Walsh*, middle July, double, white, same long season and good foliage as *Rosa Wichuraiana*, the *Memorial* rose of which it is practically a

double form; *†*R. Wichuraiana*, which is blooming at this time, is the parent of many of the varieties named above, and is itself a very attractive rose.

**Wisteria chinensis*. A strong, twining vine, with long, hanging clusters of white or purple flowers, according to variety, in middle and late May. Leaves alternate, compound, large, loose, and feathery. Beautiful in flower, graceful in habit, satisfactory in foliage, and vigorous and hardy at all times.

Large trees for wind protection and for background setting to the house.

Deciduous: These deciduous types are dense and compact in habit and make a good screen or background even after the leaves are gone in winter.

Acer platanoides.
Acer saccharum.
Æsculus Hippocastanum.
Fagus sylvatica.
Quercus alba.
Tilia europæa.

Evergreen: The Scotch pine (*Pinus sylvestris*), Norway spruce (*Picea excelsa*), and Colorado blue spruce (*Picea pungens*) are probably the three most commonly planted evergreen trees. The Scotch pine is the best of the three for neutral mass planting but none is so satisfactory as the hemlock or the pines listed below. The Scotch pine has an irregular spreading habit with bluish green foliage, salmon-colored limbs and trunk and picturesque habit when old. It grows rapidly but is short-lived in America. The Norway spruce and Colorado blue spruce are both conical evergreens and for this reason alone they are always emphatic and conspicuous. Even when planted in mass the individuals are so distinct that it requires years for them to merge into a uniform solid mass. Comparing a solid planting of Norway spruce with a similar planting of hemlock, it is seen that in the former every individual spruce is stiff and conical and remains so for years, while the hemlocks with their graceful form and habit have lost their individuality and merged into one indefinite mass. The Norway spruce is also too somber and funereal for cheerful home-ground planting. It is also short-lived in America and while hardy and rapid-growing it begins to go back and die at the top after forty or fifty years except in very favorable locations. The Colorado blue spruce is also short-lived in the eastern states and is altogether too conspicuous and emphatic both in form and color for neutral background planting.

Pinus austriaca.
Pinus resinosa.
Pinus Strobus.

Pseudotsuga taxifolia. This is a large conical tree like Norway spruce and therefore not so good for neutral background planting as either the pines or the hemlock mentioned in this same list. But it is the best of the conical spruce or fir type because more graceful in habit, with soft more flexible foliage which is green or gray-green in color. It is a vigorous grower and though little known it is a very promising evergreen tree. Only the Rocky Mountain form is hardy in the East.
Tsuga canadensis, the common hemlock.

Rapid-growing trees for screens. As a class, the rapid-growing trees are weak-wooded and transient. They are cheap and are usually thought of as fillers for temporary or quick effects until more permanent trees can be established.

Deciduous:

Acer Negundo.
Acer saccharinum.
Populus, *Carolina poplar*.

Evergreen:

Picea excelsa.
Pinus sylvestris. These are probably the fastest growing evergreen trees but they are not so long-lived as white pine, nor do they make either as graceful or as effective screen.

Screens tall and narrow (10 to 15 feet). Space the plants 2-3 feet apart in single row. For taller and more rapid-growing material, use Lombardy poplar (*Populus nigra* var. *italica*), or upright sugar maple (*Acer saccharum* var. *monumentale*), 6 feet apart in the row. This latter is a new and very desirable form. It is durable and slower-growing like the sugar maple but narrow and upright like the Lombardy poplar. Bolle's poplar (*Populus alba* var. *pyramidalis*) is a narrow upright form of the European white poplar and is just as undesirable as that tree. Moreover, the white woolly coating on the under side of the leaves makes the tree very conspicuous and when pronounced color is thus added to narrow upright form the tree becomes too emphatic for ordinary use. The Lombardy poplar with its normal green foliage is much safer to use when either vertical emphasis or a tall narrow screen is needed.

Deciduous:

Carpinus Betulus var. *globosa*. This is a compact upright variety of the European hornbeam. Excellent hedge-plant but very slow-growing. A plant standing in the open at Arnold Arboretum, Boston, has grown 6 feet wide and 12 feet high in 25 years. Perfectly hardy and, like *Berberis Thunbergii*, so dense that it makes a definite screen even after the leaves have fallen.

Quercus pedunculata var. *fastigiata compacta* (a compact upright form of the English oak).

Evergreen:

Chamaecyparis nootkatensis. This is little known in the East as yet but has all the requirements for an ideal hedge-plant, tall and narrow. Plants observed in the open at Ithaca, New York, are perfectly hardy and have grown 5 feet wide and 7 feet high in twelve years. They have not been protected nor trimmed nor specially cared for in any way. They are upright and oval in shape and very dense and compact. The foliage is thick and soft to the touch.

Juniperus chinensis. Resembles the native red cedar, *J. virginiana*, but is better because the foliage does not brown in winter. Also the leaves are more spreading and their bluish gray upper surfaces more noticeable which gives the spray a fuller and lighter-colored appearance.

Juniperus communis var. *hibernica*. This should be trained in the nursery to one central stem. When young the Irish juniper is a handsome narrow upright plant with bright gray-green foliage; but it grows much more rapidly than other cedars and soon looks miserable because, as now grown, its more or less equal upright parts become too heavy to support themselves and spread apart destroying the symmetry of the plant as well as revealing the dead and unsightly inner foliage.

Juniperus virginiana.

Taxus baccata var. *hibernica* (not quite hardy above N. Y. City).

Thuja occidentalis var. *pyramidalis*.

Thuja orientalis. This resembles the native *arbovitæ* but is more handsome. Its branches and branchlets are also more distinctly vertical and the foliage smaller and brighter green.

Shrubs for screen border-planting.

Small (2 to 4 feet) (other native plants not so dense in habit but with good foliage will make very effective screen-planting when massed together):

Deciduous:

Berberis Thunbergii (occasionally 6 feet).

Catalpa Bungei. This is the trade name for *C. bignonioides* var. *nana*. It is simply a dwarf variety of the southern catalpa and makes a dense round bush when growing on its own roots. It is often grafted high on upright stem and planted as a substitute for bay trees.

Chenomeles japonica.

Deutzia gracilis (2 to 3 feet).

Deutzia Lemoinei (3 to 4 feet).

Dirca palustris. This has thornless flexible leathery twigs but is dense and symmetrical like *Berberis Thunbergii*. If allowed to grow naturally it will make good low hedge.

Hypericum aureum.

Hypericum prolificum.

Kerria japonica.

Ligustrum Ito var. *Regelianum*.

Ligustrum ovalifolium. This is not hardy north of Philadelphia and can be used only for low hedge in the North. May be cut to the ground and will spring up vigorously every year.

Lonicera thibetica.

Lycium chinense.

Lycium halimifolium.

Philadelphus coronarius var. *nanus* (2 to 3 feet).

Philadelphus Lemoinei (in variety, especially var. *Avalanche* Candelabre, and *Gerbe de Neige*).

Philadelphus microphyllus (this and *P. coronarius* are the original parents of the *Lemoinei* hybrids).

Rhus canadensis.

Rosa rugosa (often 5 or 6 feet high but better if kept low and vigorous by frequent renewal from the base).

Rosa rugosa var. *Blanche de Coubert* (beautiful semi-double, white).

Rosa spinosissima var. *altaica* (often 5 feet).

Spiraea Bumalda, Anthony Waterer variety (2 feet).

Spiraea japonica (3 feet).

Spiraea Thunbergii.

Spiraea trilobata.

Symphoricarpos albus (often 5 feet).

Symphoricarpos orbiculatus (2 to 3 feet).

Vaccinium corymbosum (often 5 to 6 feet).

Viburnum Opulus var. *nanum* (2 to 3 feet. Seldom has flowers).

Evergreen:

Buxus japonica. A new and hardy box; will probably reach 8 feet, but is slow-growing and easily restrained by clipping.

Buxus sempervirens. Must be protected in the North but is hardy and tree-like in the South.

Chamaecyparis obtusa var. *nana* (6 to 8 feet, but very slow-growing and easily restrained).

Evonymus radicans var. *vegeta* (2 to 3 feet; with a little clipping can be brought into a low natural hedge mass).

Ilex glabra.

Picea excelsa var. *Clanbrazilliana*.

Pieris floribunda (2 to 3 feet).

Pinus densiflora var. *pumila* (often 6 feet).

Pinus montana var. *Mughus* (often 5 to 6 feet).

Rhododendron, *Boule de Neige* (white, blooming-period early).

Rhododendron carolinianum. Color lavender-pink, blooming-period very early. See note on page 2692.

Taxus cuspidata var. *brevifolia*.

Thuja occidentalis var. *nana*. This may reach 3 to 4 feet but is very slow-growing and easily restrained by clipping.

Thuja orientalis var. *nana*. This may reach 3 to 4 feet but is very slow-growing and is easily restrained by clipping.

Medium (6 to 8 feet) (other native plants not so dense in habit but with good foliage will make very effective screen-planting when massed together):

Deciduous:

Acanthopanax pentaphyllum.

Acer palmatum (often larger but slow-growing).

Berberis vulgaris.

Cornus paniculata.

Evonymus alata.

Forsythia suspensa. Good definite form and best for individual specimen planting.

Ilex verticillata.

Lonicera fragrantissima.

Lonicera Morrowii.

Myrica carolinensis. Sometimes much larger than 6-8 ft. Can be kept lower very easily by thinning out and renewing from the base. Is still known in commerce as *M. cerifera*. Ranges north to Nova Scotia near the coast. Is more shrubby, with blunt leaves which are broader and more oblong than those of *M. cerifera*.

Philadelphus inodorus. Has more definite and graceful form than *P. coronarius* and dark green almost glossy foliage.

Rhodotypos kerrioides.

Spiraea bracteata.

Spiraea gemmata.

Spiraea prunifolia var. *flore-pleno*.

Spiraea Vanhouttei.

Evergreen:

Ilex crenata.

Kalmia latifolia (sometimes higher than 6 to 8 feet).

Picea orientalis. Large tree but adapted to small-scale planting because very slow-growing and also because easily restrained by pruning or pinching back.

Rhododendron, *Caractacus* (color bright red, blooming-period medium).

Rhododendron catawbiense var. *album*. Compact habit of *R. catawbiense* but flowers white, blooming-period early.

Rhododendron delicatissimum (color blush-white, blooming-period late).

Rhododendron Everestianum (color lavender, blooming-period early).

Rhododendron, H. W. Sargent (color dark red, blooming-period late).

Rhododendron, Lady Armstrong (color pink, blooming-period early to medium).

Rhododendron purpureum elegans (color purple, blooming-period medium).

Taxus cuspidata.

Tsuga canadensis. The most graceful and effective large evergreen for screen-planting. Takes up less room than white pine and is much slower-growing. Can be restrained easily and therefore is adapted to small-scale planting.

Large (10 to 15 feet) (other native plants not so dense in habit but with good foliage will make very effective screen-planting when massed together):

Deciduous:

Acer campestre (small compact tree, dense foliage).

Acer ginnala (gorgeous autumn color).

Acer platanoides var. *globosum* (dwarf, dense, slow-growing).

Benzoin aestivale.

Berberis aristata.

Carpinus Betulus. Much used for hedges. Better than our native hornbeam, *Carpinus caroliniana*.

Cornus mas (small compact tree, 15 to 20 feet).

Cotinus Coggygia.

Crataegus coccinea.

Crataegus Crus-galli.

Crataegus Oxyacantha var. *Paulii*.

Crataegus punctata. All these thorns are better as natural screens with room to spread at the bottom than when confined in restricted hedge lines.

Hibiscus syriacus. Ten feet, dense and compact making good tall hedge, but thin at bottom. Plant low dense shrubs in front. The white variety is the best.

Laburnum alpinum (compact large shrub or small tree 20 to 30 feet high).

Ligustrum Ito.

Ligustrum vulgare.

Lonicera tatarica.

Philadelphus coronarius.

Pyrus coronaria (small tree).

Pyrus pulcherrima (small tree).

Rhamnus cathartica.

Rhamnus Frangula.

Syringa chinensis var. *alba*.

Syringa chinensis var. *Sougeana* (var. *rubra*).

Syringa vulgaris.

Viburnum dentatum. Will reach 10 to 12 feet, but may be restrained easily by gradual renewal from the base.

Viburnum Lantana.

Viburnum prunifolium (small tree).

Evergreen:

Ilex opaca.

Pinus montana a low, bushy tree, 20 feet high and 20 feet broad; very slow-growing.

Pinus Strobus. Excellent for screen-planting. More graceful, effective, and permanent than Norway spruce or Scotch pine.

Pseudotsuga taxifolia.

Rhododendron album elegans (color white, blooming-period medium).

Tsuga canadensis. The most graceful and effective large evergreen for screen-planting. Takes up less room than white pine and is much slower-growing. Can be restrained easily and therefore is adapted to small-scale planting.

RALPH W. CURTIS.

Winter protection of planting.

Winter protection is the preparing of plants to withstand the winter (Figs. 3032-3047). All plants are usually hardy in their own habitat, but many become tender when removed to a colder climate, requiring artificial protection. A permanent covering of snow furnishes ideal protection, but unfortunately the American winters are very changeable. Continued steady cold is seldom injurious, but the alternate freezing and thawing

toward spring are often fatal, the damage varying according as the situation is wet or dry and the soil light or heavy. For example, shallow-rooted plants, as *Lobelia cardinalis*, will often be thrown out of the ground in clayey soil. Such damage may be prevented by placing sods over the plants. Gailardias will winter safely in light well-drained

3032. Straw overcoats for roses.

soils with ordinary protection, but perish if wet and heavy. The remarks in this article are meant to apply in the vicinity of Chicago.

Winter-covering intercepts the sun's rays and retards premature activity. It is as essential "to keep in the cold" during temporary warm spells as it is to retard excessive depth of frost. More damage is generally done in February and March than earlier. Roses and other shrubs may be prepared for the winter any time from the last half of November until well into December, but any plants of an herbaceous nature may be covered much earlier. Where field-mice are troublesome it is well to defer covering until after a good freeze, so that these nibblers may seek other winter quarters. Rabbits are fond of the Japan quince, *Spiræa Vanhouttei*, *Evonymus alata*, and some others, and often damage newly planted material the first winter. When the branches are beyond their reach, protect the trunk with straw, tar paper, or burlaps, which will also prevent sun-blistering. If the shrubs are in groups or low-branched, run wire netting around them. Fall-planted material should be better protected against frost than established plants of the same species. All the Japanese flowering forms of the plum, peach, and cherry tribes should have their roots mulched 4 or more inches deep. The fatal damage in the winter of 1898-1899 was at the roots, not overhead. Figs. 3032, 3033 show protection by means of straw and boughs; Figs. 3034-3036, protection inside of boxes, barrels, and wire netting.

Plants with evergreen foliage, like *Heuchera sanguinea*, are safer with a covering that will not mat down and rot the foliage or injure the crown. The danger is in open, wet seasons. Forest leaves are excellent for winter covering, provided they do not mat down. Oak

leaves are good, but those of elm, maple, and other trees that shed their foliage early are soft and mat too much. Leaves may be held in place by evergreen boughs, brush, or tops of bushy perennials like the native asters, or coarse strawy material. When leaves are used in barrels or boxes, the top of the package should be water-tight, and the leaves dry when put in. This precaution is not essential in all cases, but it is a safe rule to follow. Tar paper is comparatively cheap and comes handy in many phases of winter-covering. Gather the leaves when they are dry, and store under shelter until wanted. Save vines like those of *Clematis paniculata* and pole limas; they are good for covering climbing roses that are almost hardy. These keep off the bright sun when the plants are in a semi-frozen condition, shield them from the drying winds, and retard premature starting of the flower-buds. *Forsythia suspensa* trained as a climber on a south wall is benefited by such covering, or by burlaps, as its sheltered position induces activity too early and its flowering buds become a victim to late frosts. Any rhizomatous iris, such as the German iris, should be planted where surface drainage is ample, and in the case of young plants, or those recently divided, not covered with heavy manure or they are likely to decay in wet weather. Cover such plants with light material. Old established plants seldom need protection. *Chrysanthemum coccineum* requires similar conditions and treatment. All lilies except the hardiest, such as *L. tigrinum*, *L. elegans*, *L. canadense*, *L. superbum*, *L. philadelphicum*, *L. speciosum*, *L. tenuifolium*, and so on, are best covered by a mound of ashes—wood or coal—which retains an even temperature. The other lilies may be mulched with manure and *L. candidum* with leaves. Eremurus in all its species, and *Alstræmeria aurantiaca*, require a deep box of leaves and the surrounding soil well mulched. An inverted V-shaped trough placed over such low edging plants as *Veronica circeoides* and *Thymus Serpyllum* var. *montanus*, is beneficial. It is well to take up a few plants of *Monarda didyma*, the double perennial sunflower, and *Thymus Serpyllum*, and winter them in a frame, over which place a wooden shutter to shed rain, placing leaves or manure on those that remain

3034. One way of protecting young rhododendrons. The space inside the wire netting is filled with autumn leaves.

Where permanent windbreaks, such as plantations of evergreens, buildings or solid fences, do not exist, temporary ones should be made of boards, evergreen boughs, corn-stalks, and the like, to protect arboreal plants that are not quite hardy, e. g., in this climate *Halesia carolina*, and in the eastern states *Magnolia grandiflora*, hollies, and the like. Place the windbreak at the sides toward the prevailing winds, generally

3035. Protecting plants by covering with a box inside which are placed leaves or straw.

north and west, and at the sunny side of any evergreen that browns. The boughs or stalks may be attached to wire netting or to cords fastened to stakes.

The so-called retinisporas may have placed over them an empty box open at the top. Shrubs that are still more tender should be boxed, the box having a tight top and ventilation at the sides. In all cases mulch well at the roots. *Magnolia Soulangiana*, *M. speciosa*, and plants of similar degrees of hardiness may have their branches tied in and empty casks placed over them, one sitting partially inside the other, and held in place by stakes. Put a cone-shaped covering over the top to shed the snow. Or poles may be set close to the tree, wigwam fashion. Wrap these with burlaps, or wind string around them for the straw to lean against, and in both instances wrap with straw.

The so-called hardy climbing roses, such as the Seven Sisters and Prairie Queen, which are hardy without protection, but are benefited by it, Wichuraiana and its hybrids, Paul Carmine Pillar, Russell Cottage, Crimson Rambler, Thalia, and Lord Penzance Sweetbrier hybrids, if against a wall, may have clematis or other vines placed thickly over them; or if in an open exposed situation, they may be wrapped in straw. (Fig. 3033.) Better still, hill up the soil rather high at the roots,—to prevent breaking and to afford protection and drainage,—and then take the trouble to extend the mound in the form of a gradually diminishing ridge. Bend the canes along the ridge, choosing a time when there is no frost in them; then cover the canes with tar paper, over which place soil, strawy manure, or any warm covering. If the presence of a lawn prevents this method, lay on the grass and cover with a water-tight box filled

with leaves. Canes will rot directly under an open knothole. In the spring allow them to remain prostrate some time after uncovering to inure them gradually to the change and to induce the lower buds to strengthen. Hybrid Perpetuals, the tender forms of Moss roses, Hermosa, Clothilde Soupert, and the Dwarf Polyanthas, may be wrapped, boxed, or bent over and covered with soil. Those in beds may be bent over, the tops tied to the

base of their neighbors, lead tags bearing numbers fastened to each plant, and a record taken of their names, and all summer labels stored to prevent loss when removing the leaves in the spring. Make a solid frame around them, higher at one end, and fill with leaves so as to cover the plants. Lap the roof-boards; they will shed water and allow ventilation. In the spring remove the leaves, replace the top for a few days, but let the sides remain for a week or so to shield from cold winds. Keep the plants prostrate until cut back.

The tender Hybrid Teas require special attention. Cultivation and watering should be discontinued in September in order to retard a late growth, but if the fall is a dry one, they should receive a thorough soaking late in October. Early in November hill up the soil around the plants to a height of 6 to 8 inches. After there is a crust of frozen soil a few inches thick, fill up with dry leaves to a little over the height of the hills or higher. Then board up the bed some 2½ feet high at one side and 2 feet at the other, and cover top with boards or tar paper, the object being to keep the leaves dry. Hybrid Perpetuals, or in fact any semi-hardy rose of low growth, may be protected as above. In most winters the Hybrid Teas can be safely carried over by hilling up the soil as described and covering with hardwood leaves 18 to 24 inches deep, held down by evergreen boughs, brush, or corn-stalks.

Field-mice or the smaller moles are troublesome sometimes where any open or loose material like leaves or straw is used for winter protection. Plants in cold-frames are often destroyed. This may be prevented by the following method: Procure some poisoned wheat and place in the interior of a 4- or 5-inch common

3037. Deep pit built like a coldframe, for carrying half-hardy woody plants over winter.

drain-tile. Place these tiles in the frames or among the roses, using ten grains of wheat to a tile. When spring comes lift up the tile carefully, so as not to spill the wheat and count the grains; by the use of the tiles one keeps track of the wheat and does not endanger the birds.

Tree peonies and yuccas should have an empty box placed over them, large enough to prevent the plant from touching the wood. *Hibiscus syriacus*, diervillas, deutzias—except *D. Lemoinei* and *D. parviflora* which are hardy—*Itea virginica*, *Cornus mas*, and the like, are wrapped in straw, and when the wrappings exceed 4 feet in height they should be staked to prevent high winds from toppling them over. Rhododendrons when planted out are taken up, the roots given a good soaking in a tub, and replanted in cold pits, or in boxes placed in a coldhouse or pits. In the spring, another bath is

3036. Plants protected in a barrel covered with burlaps.

given them and the soil firmly pounded around them before replanting. This is essential for continued vigor. Cut all vines of the clematis to within 1 or 2 feet of the ground and lay them down, first mounding the soil a few inches if surface drainage is not good and cover with ashes, boxed leaves, or soil, or mulch well and wrap the canes with straw. If close to a porch or steps, do not let the swept snow stay over them, unless well protected, as this snow solidifies and excludes air. If, as some now think, the broken outer skin of the hybrid forms subjects them to disease, then these varieties should not be bent over, but staked and wrapped. It is

3038. An outside cellar, in which to store roots and tubers, and pots of resting plants.

best not to cut the foliage of the eulalias or the Japan iris, as it, of itself, is a good protection, but manure at the base is essential. Cut down *Arundo Donax*, cover heavily with any material, and cover all with tar paper or water-tight shutters. Place half-rotted leaf-mold over fern-beds, narcissi, English and Spanish iris or any early-blooming bulbous plant, or a light strawy covering that is easily removed. Fine old manure a few inches thick is good and can remain. Place a good coating of stable manure around the trees on the lawn, and when they have been established any length of time bear in mind that the feeding-roots extend out as far as the branches do. The soil under them has a double duty to perform—to sustain both the tree and the grass.

Place short stakes around groups of platycodons, *Asclepias tuberosa*, or any other plants that are late to appear in the spring. Otherwise they may be overlooked in the spring and injured by digging. Examine all labels and see that none is cutting into the limbs of trees. Replace all rotten or defaced ones in the borders, using heavy labels, as thin ones often break off and are carried away when the surplus manure is removed. Cypress is a good material for labels. A good label for young trees and shrubs is made of a thin sheet of copper. The name is written with a stylus and a thin white paint rubbed on so as to fill in the depression. The label is fastened to a copper wire ring 3 or 4 inches in diameter, placed around the trunk and allowed to lie on the ground. Such a label is durable, unobtrusive and requires no attention for fear of cutting the wood, nor can it be lost.

W. C. EGAN.

Structures for the winter protection of plants.

Pits, cold pits, storage-pits and plant-cellars (Figs. 3038-3047) are structures, with the greater part sunk beneath the surface of the ground, built for the purpose of protecting plants in winter without continued fire-heat. They are employed almost exclusively for storing dormant plants. They are not suitable for storing growing plants any length of time, neither are they houses in which to grow plants. They should face the

south and be sheltered against north winds by buildings or other windbreaks. Owing to their position they should be put in well-drained ground only and well protected against surface water. A well-designed frame-yard is the best possible place for small pits.

The coldframe used by market-gardeners for wintering cabbage and lettuce for spring plantings, or by the florists for pansies, primroses, forget-me-nots, and the like, is really a simple pit. Such shallow pits, with proper protection, are useful for many other small plants which would be injured by severe weather. A deep pit, like a coldframe, is shown in Fig. 3037. A pit built on the plan of the old-fashioned "outside cellar" (Fig. 3038) is useful for storing tubers and roots. See that it is well ventilated. A section of another pit is shown in Fig. 3039. More elaborate pits, for accommodating large plants, are illustrated in Figs. 3040-3047.

Double glazed hotbed sashes are now used and can be employed for the pits shown in Figs. 3043-3046, or wherever winter protection is required, as it takes too much time to cover the ordinary sash with mats and shutters. These sashes cost a little more and they are heavier; it may be well to employ, therefore, a method for ventilation which obviates the necessity of lifting. They lessen the labor and let in sunlight all day. A thin layer of air is shut in by glass; the depth of this layer is the thickness of the sash bar; it keeps in heat and so keeps out frost. It is possible that some dust and perhaps fungous growth may accumulate or form within the layers. The glazing can be done at home, the lower glass being put in without putty and held in grooves on sides and ends and on the sash-bars by thin strips of wood.

For forms of pits, consult Figs. 3043-3046. Figs. 3043-3045 show inexpensive and convenient pits for small and medium-sized plants. They may be built 4 feet or less below the level of the ground, the height and width as shown in the diagrams; the length should be some multiple of 3, any thing between 9 and 30 feet, so that the glass roof may be made of hotbed sash and also protected by the straw mats and wooden shutters in common use. See *Hotbeds*. These pits are useful for storage in winter and also for carrying some of the hardier greenhouse plants in autumn until the houses are relieved of the chrysanthemum crop. Figs. 3043, 3044 make light hotbeds in spring, if filled with the leaves which formed their winter protection, and are also available for growing such plants as euphorbia during the summer. They are generally too deep for dung hotbeds. These pits are planned to run east and west. If Fig. 3045 is thus placed, the roof on the north side may be made of plank instead of glass, but if it runs

3039. Nurseryman's cold pit. A cheap device for wintering plants that require comparatively little light.

north and south it should have a glass roof on both sides. Easy access to all is obtained through the roof by removing a sash. Sometimes a door can be built at one end. Fig. 3043 does not cost much more than Fig. 3044, and furnishes more room. By putting a few doors in the board roof, excellent ventilation and access is provided. Fig. 3045 gives the best head-room, but is rather dark for evergreens with soft foliage, e.g., *Cytisus canariensis*, unless the whole roof is glass. A

pit like this has always been used in the Arnold Arboretum for wintering seedlings, rooted cuttings and grafts,—young stock grown in flats but too delicate for the open ground. The arrangement of shelves shown in the diagram gives storage to large numbers of these small plants.

3040. A durable storing pit or cellar for very large plants.

In Fig. 3046 is shown a small plant-cellar, more expensive but with better capacity for large plants. It should run north and south, and, excepting the glass roof, is wholly below ground, and consequently extremely well protected against frost. The door is at either end or side. By taking advantage of sloping ground it is possible to enter on the ground-floor level, which is important when large plants in tubs must be handled. In such cases a concrete floor may be built. The monitor roof provides plenty of light and ventilation; wooden shutters cover the glass in cold weather. This form of pit is not only well adapted to plants, but also is excellent for storing fruits and also brussels sprouts, celery, and cauliflower until Christmas. The forms of buildings larger than those above described vary much with different circumstances. Sometimes the cellar of a stable, tool-house, or other outbuilding can be utilized. The chief consideration is protection against frost, but provision must be made for thorough ventilation, and against a too high temperature in the autumn and early spring. It is because it is hardly possible to provide for these matters that dwelling-house cellars do not make good pits; they cannot be sufficiently ventilated to keep the temperature low enough except in the middle of winter. Growth is incited and cannot be maintained owing to lack of light.

Owing to their position, pits cannot well be made of wood, plank and cedar posts lasting from 4 to 6 years only. For large pits, stone and brick are most economical for walls and ceilings; for small ones concrete probably makes the cheapest and best wall; hollow tile might be used. At the Bussey Institution the concrete walls of several small pits have stood 15 to 20 years without showing any sign of deterioration.

An excavation of the required dimensions is made, with due allowance for the walls. Inside the excavation a plank molding-frame is built at the proper distance; viz., the thickness of the walls, from the walls of earth which should have been cut as true as possible. This frame, which should also be true and plumb, is carried to the required height for the inside face of wall and another frame is made at the proper distance on the surface of the ground, the inner face of which will be the outside face of the completed wall. These frames must be well braced; they carry a heavy load until the cement hardens. It is not necessary to make a complete frame for the whole pit at once; one end and a half of both sides can be built first, and the same frame reversed will serve for the remainder. Use a good quality

portland cement mixed one part of cement to two of sand with four or five parts broken stone or gravel which should not be larger than an egg; for floors the broken stone or gravel may be increased to seven or eight parts. The whole should be completely and quite carefully blended with hoe or shovel until each stone is coated. Throw this mass into the space between the molding-frame and earth wall and settle compactly with a rammer. It is not advisable to mix more than a barrel at once, nor so much as this unless at least six men are employed. Continuous batches are made until the work is finished. When the top layers are going in, insert $\frac{3}{4}$ -inch iron bolts 6 to 8 inches long at intervals of 6 feet. These secure the wooden sills. In warm dry weather the frames can be removed within twenty-four hours or less, but first examine carefully the condition of the concrete. After removal, smooth off any roughness and grout in with a whitewash brush a coat of portland cement mixed with water, but without sand, thus obtaining a good color and a more homogeneous surface. For several days the work should be shaded and occasionally sprinkled with the hose. Do not attach the woodwork until the concrete is fully hardened. One and one-half barrels of cement make about 1 cubic yard of concrete, that costs, in place, between five and six dollars, somewhat less if the cost of labor, sand, and gravel is moderate. Build in June or July, so that the concrete will be thoroughly dry before frost.

The construction of a brick roof is shown in Fig. 3046. Concrete could also be used. A good grade hotbed sash make the best glass roof. All sills, cross-bars, and the like, should be made of cypress and painted. The woodwork must be made strong to endure the continual exposures. It is false economy to stint in quantity or quality. In cellars for nursery stock, a comparatively small amount of light is required, and the low roof is boarded in and shingled, building-paper being used. Planks may be substituted for boards, or the roof may be double.

Sand or gravel, 1 foot deep, makes the best floor, or half sand and half loam where plants are to be heeled-in. A concrete floor should be used only where the drainage is absolutely perfect.

The sides and ends should be banked with leaves or other material. (See Fig. 3039). In the vicinity of Boston this should be done about November 15. The same covering can also be given to low roofs. The glass is protected by mats and shutters, much as in ordinary hotbeds. It is a good plan to have on hand an extra supply of dry meadow hay to give additional shelter in zero weather.

3041. A doorway in Fig. 3040.

Pits like those shown in Figs. 3043 and 3045, like greenhouses, should carry more than one "crop." In early autumn they hold chrysanthemums, carnations, stevias, and the like; next *Rhododendron* (*Azalea*) *indica*, *Cytisus canariensis*, heaths, and the like, some of which remain for the winter, while others are replaced by

3042. Winter protection. Plants carried over winter in a living condition in an unheated glasshouse.

hardy shrubs, bulbs, and other plants for forcing. For spring and summer use, see above. In eastern Massachusetts gardeners begin to use them in September, but the final storage sometimes is not finished until Christmas. The longer the plants can be kept in the open air the better fitted they are for their winter quarters.

In the care of pits, watering and ventilation are of prime importance. When first housed the plants should be well watered, and, if this is carefully done, it will often be found that no further water is required for plants in tubs and large pots (10 inches or more). This also is true of heeled-in stock. Everything, however, should be so arranged that inspection is easy, and water should be given when necessary. Plants on the shelves, particularly in small pots (4-inch), will go dry oftener than those placed on the gravel floor. It is best to water on bright days, when the sashes can be removed. The great difficulty in keeping plants in good condition is owing to the condensation of moisture within the pits at times when it is impossible to open them on account of severe weather; therefore no more water should be given than is absolutely needed. As long as the weather permits, keep the sashes off or the windows open night and day, and afterward open up whenever possible. On sunny days ventilate whenever the thermometer registers over 20° F., but do not begin until the sun strikes the frames, and shut off early in the afternoon. On mild days, with the mercury above freezing, remove the sashes entirely. This is the best way to get rid of the moisture-laden air, and is essential for keeping evergreen plants with soft foliage in good condition. To change the air in large cellars is more troublesome; here it is advisable to build an open fireplace in which a brisk fire may be kindled on mild days when all windows can be unclosed, thus obtaining a

3043. One of the simplest and least expensive forms of cold pit for small and medium-sized plants.

better circulation than is otherwise possible. Sometimes these large cellars have a line of hot-water pipes or other means of heating, by which not only is better ventilation secured but also additional protection in severe weather.

An unheated greenhouse (Fig. 3042) can sometimes be used advantageously, not only for protection but, if it is warm enough, for growing plants in spring and autumn, and to a certain extent in winter. It is really a pit 5 or 6 feet deep built below ground and attached on the south side to some building already on the place. It might not be satisfactory for the extreme North but in southern New England and the middle states it is a great help: in European gardens it is sometimes called an alpine house, or, if it is larger and better built, a winter-garden. Give a southern exposure and have it so arranged that the floor is on the same or nearly the same level as the cellar floor; if this cellar is heated, so much the better. The cellar will be convenient for various operations, also for storing soil and tools; water should be handy. A door between it and the cellar is a necessity, but there need be none on the outside. The form of roof can be either lean-to or three-quarters span; in the latter form boarding, double if possible, can cover the roof next the house. Use double glazed glass and provide plenty of ventilation by glass or board shutters; this last is most important. The dimensions should not be less than 10 feet in width and may be more; the length can be any multiple of three so that hotbed sash can be used for the roof. The interior layout should be a walk, not over 2 feet wide, so placed that convenient and economical access is given the plants. These may be grown on benches, either solid or of boards, or planted in the earth. The great advantage of such a structure is that the plants can be handled from the inside in all weathers. The hardier plants, like wallflowers and violets, bloom all winter; in autumn it can be used to prolong the chrysanthemum season, in spring it is a good place for starting seedlings, e. g., lettuce, cauliflower, and cabbage, and, if warm enough, an inside hotbed can be

3044. A well-ventilated cold pit, roomier than the preceding and not much more expensive.

made to start tomatoes, peppers and eggplant also; in it most of the plants named below can be stored or grown. Many plants of doubtful hardiness or of small size can be wintered and tried out. It is much simpler to handle than pits or frames, largely on account of easy access and the storage capabilities of the cellar. It makes a good place to store plants for forcing and will even flower well tulips, hyacinths, and narcissi. A three-quarters span 12 by 15 feet with 8 feet of glass roof, in southern Massachusetts, well protected in all ways, has recorded on a self-registering thermometer only 24° F. in the last three years, outside temperature going as low as -10° F.

Following is a list of plants that may be wintered in pits and frames with satisfactory results. The list is made for the neighborhood of Boston.

A. Hardy plants.

1. Nursery stock of every description.
2. Stocks, cions, and cuttings for winter work.
3. Young nursery stock,—seedlings, cuttings, or grafts too delicate for planting in autumn.
4. Hardy plants for forcing or winter decoration.

The temperature of pit or cellar for the above plants should be 35° F. or even lower occasionally. The larger plants should be heeled in on the floor in sandy loam or in bunk-like shelves along the sides. Instead of loam, sphagnum can be used and is particularly good for cuttings and grafting stock. The very young stock is stored in flats or pans in which it has been grown. For forcing stock, see *Forcing*, pages 1265-1267.

AA. Tender and half-hardy plants.

Those marked with a star (*) are more tender and should not be exposed to frost. They should also be kept in the driest part of the pit.

1. *Alstroemeria*, canna, dahlia, gladiolus, *Milla biflora*, montbretia, oxalis for summer bedding, tuberoose, tigridia, *Zephyranthes Atamasco*, *Z. candida*. Keep the above in dry house-cellar, where no frost penetrates, temperature 35° to 40° F. Dahlias and cannas can be covered with dry sand if prone to wilt. Tigridias should be hung up in bags to avoid mice.

2. Agave, aloe, *Lippia citriodora*, *Datura suaveolens*, some of the harder cacti, e. g., *Selenicereus grandiflorus* and *Opuntia Ficus-indica*, *Cordyline indivisa*,

pota in variety, rhododendron (tender hybrids), *Rhododendron indicum*, *Romneya Coulteri*, roses (Bourbon, Noisette, China, Bengal, and other tender varieties), *Rosmarinus officinalis*, *Senecio grande*, *Sequoia gigantea*, taxus, *Trachelospermum jasminoides*, *Ulex europæus*.

3046. A small plant-cellar for wintering large plants. It is also excellent for storing vegetables and fruits. It combines perfect ventilation with extremely good protection against frost.

The above plants are commonly handled in pits for various reasons. In eastern Massachusetts, with the possible exception of those marked thus (*), they will bear a few degrees of frost, if not too long continued, without harm. The average temperatures of the pit should be just above freezing, say 35° F. The value of these plants depends upon not only carrying them through the winter in good condition, but also in giving them a good start in the spring. For this purpose a cool greenhouse must be provided; a cold grapery or a house constructed from the sashes used on the pits is equally good, in which the plants can be properly grown until it is warm enough to put them out-of-doors.

4. *Anemone japonica* and *A. coronaria*, *Bellis perennis*, *Dianthus Caryophyllus* (clove pinks and European carnations from seeds), *Galax aphylla*, myosotis, primula in variety, including auricula, Persian ranunculus, *Viola odorata* (tender sorts), pansies, wall-flowers, lettuce, cabbage, cauliflower and parsley. These plants are wintered in coldframes, which should vary in depth with the size of the plant; sometimes the plants are grown and flowered in the frame, at others they are bedded out when the season permits.

5. *Arisæma*, arum, calochortus (different species), freesia in variety, iris (tender species), ixia, sparaxis. The above plants can be potted and carried in a pit or frame until wanted in the greenhouse.

B. M. WATSON.

3045. A shelved cold pit for wintering young stock grown in flats, seedlings, rooted cuttings and grafts.

fuchsia, *Yucca gloriosa* and probably other genera and species of succulent plants. Keep at temperature 35° to 40° F. in a very dry house-cellar, with as much light as possible; too much moisture is destructive.

3. *Abelia* in variety, **abutilon*, **acacia*, *Acanthus mollis*, **Agapanthus umbellatus*, *Araucaria imbricata* and *A. excelsa*, *Aucuba japonica*, bamboos, *Buxus sempervirens*, **Callistemon* sorts, *Calluna vulgaris*, **Camellia* (different species, including the tea plant), *Ceanothus azureus*, *Cedrus Libani* and *C. Deodara*, *Cephalotaxus drupacea*, **citrus* in variety, *cistus* (different species), *cotoneaster* (tender sorts), *Cryptomeria japonica*, *cupressus* (tender sorts), **Cytisus canariensis* and **C. racemosus*, **Daphne odora*, **erica* (hardier sorts), *Eriobotrya japonica*, *Erythrina Crista-galli*, **Eugenia Jambos*, *Evonymus japonica* (tender varieties), *Ficus Carica*, *Gelsemium sempervirens*, *Gordonia alata*, *grapes* (tender kinds), *Hedera helix*, **Hibiscus Rosa-sinensis*, *Hydrangea hortensis*, *Ilex Aquifolium*, *kniphofia*, *laurestinus*, *Laurus nobilis*, *lagerstræmia*, *Magnolia grandiflora*, **Meratia præcox*, *Myrtus communis*, **Nerium Oleander*, *Olea europæa*, **Osmanthus fragrans* and *O. Aquifolium*, *Passiflora cærulea*, *pernettya*, *Phormium tenax*, **Pittosporum Tobira* and others, *Plumbago capensis*, *Podocarpus macrophylla* var. *Maki*, *Prunus Laurocerasus* and others, **Psidium Guajava*, **Punica Granatum*, *retinis-*

3047. The roof of Fig. 3046.

Shrubs, small trees, and woody vines hardy in the northeastern United States.

The use of shrubs in landscape planting is explained in the preceding articles of this symposium on Planting. The illustrations, Figs. 3048 to 3060 inclusive, indicate the habit of some of the species.

- 1 before name means plant is low, 6 inches to 2 feet.
- 2 means plant is small, 3 to 5 feet.
- 3 means plant is medium, 6 to 8 feet.
- 4 means plant is large, 10 to 15 feet.
- D means dioecious, i. e., only one sex on a plant. Fruiting (i. e., pistillate) plants must be secured with also one or more pollen-bearing (i. e. staminate) plants.
- E means plant is evergreen.
- e means plant is good for edging (low, neat, and compact).
- G means plant is good ground-cover (trailing or creeping).
- H means plant is hedge material.
- P means requires protection in climate of Boston.
- S means semi-evergreen (holding leaves till December or later).
- V means plant is a vine.

EP1—*Abelia grandiflora* (much used in the South).

- 3—*Acanthopanax pentaphyllum*.
- 4—*Acer campestre* (small compact tree, dense foliage).
- 4—*Acer ginnala*.
- 3—*Acer palmatum* (often large but slow-growing).
- 4—*Acer pennsylvanicum*.

H3 or 4—*Acer platanoides* var. *globosum* (a dwarf dense slow-growing variety of the Norway maple).

- V—*Actinidia arguta*.
- 4—*Esculus parviflora*.
- SV—*Akebia quinata*.
- 4—*Alnus incana*.

Eel—*Alyssum gemonense* (6 inches).

- 4—*Amelanchier canadensis*.
- 4—*Amelanchier oblongifolia* (A. obovalis).
- 2—*Amorpha canescens*.
- V—*Ampelopsis heterophylla*.

EG1—*Arctostaphylos Uva-ursi*.

- V—*Aristolochia macrophylla* (A. Sipro).
- 2—*Aronia arbutifolia*.

2—*Aronia melanocarpa*. These two aronias will grow 6 to 8 feet, but are better if kept low and vigorous by frequent thinning out and renewal from the base.

EP1—*Arundinaria japonica*.

- Eel—*Aubrietia deltoidea* var. *græca*.
- S2—*Baccharis halimifolia*.

EP1—*Bambusa disticha*.

- 4—*Benzoin aestivale* (B. odoriferum).
- 4—*Berberis aristata*.
- 3—*Berberis dictyophylla*.

EP2—*Berberis Sargentiana* (2 to 3 feet).

- H2—*Berberis Thunbergii* (occasionally 6 feet).

EeP1—*Berberis verruculosa* (1 to 2 feet).

H3—*Berberis vulgaris*.

HS2—*Berberis Wilsonæ* (2 to 3 feet).

- 2—*Betula pumila*.

3048. A good shrub, taking its natural and characteristic form.

P2—*Buddleia Davidii* (B. variabilis) var. *magnifica* (if not protected may be cut to ground annually).

EH2—*Buxus japonica* (a new and hardy box; will probably reach 8 feet but is slow-growing and easily restrained by clipping).

EHP2—*Buxus sempervirens* (must be protected in the North, but is hardy and tree-like in the South).

EHP1—*Buxus sempervirens* var. *suffruticosa*.

- 1—*Callicarpa japonica*.
- 1—*Callicarpa purpurea*.

Both of these callicarpas are tender and require cutting back early in spring.

EeG1—*Calluna vulgaris*. Succeeds best in United States if kept low and vigorous by heavy pruning early in spring. Flowers appear in summer.

- 2—*Calycanthus fertilis*.

V—*Campsis radicans*.

2—*Campsis radicans* var. *speciosa*.

3—*Caragana frutex*.

2—*Caragana pygmaea*.

4—*Caragana arborescens*.

H4—*Carpinus Betulus*. Dense slow-growing tree, much used for hedges. Better than the native hornbeam, *C. caroliniana*.

H3—*Carpinus Betulus* var. *globosa*. This is an upright, oval form of the above. It is very dense and compact and may reach 15 to 20 feet in height, but is very slow-growing and can be restrained easily. See page 2683.

2—*Catalpa bignonioides* var. *nana*. This is known in the trade as *C. Bungei*, but is not the true *C. Bungei* from China. It is a dwarf variety of the southern *catalpa* (*C. bignonioides*). It is often grafted high on an upright stem, but if grown on its own roots it will make only a dense round bush.

1—*Ceanothus americanus*.

1—*Ceanothus hybridus*.

V—*Celastrus scandens*.

3—*Cephalanthus occidentalis*.

4—*Cercis canadensis*.

H2—*Chenomeles japonica*.

1—*Chenomeles Maulei*.

EH4—*Chamaecyparis nootkatensis*. This is a large timber tree of the north Pacific coast. It is hardy, but little known in the East. Its good qualities are compact oval shape and dense soft foliage. It is also slow-growing and may be restrained easily for small-scale planting. See page 2683.

E4—*Chamaecyparis obtusa*.

EH2—*Chamaecyparis obtusa* var. *nana*. This is the finest of the Japanese cypresses (*Chamaecyparis*), all of which were originally introduced in the trade under the name *Retinospora*. This form will reach 6 to 8 feet, but is dwarf and very slow-growing and can be restrained easily. Its foliage is small and blunt, dark green above with white Y-shaped lines below. The spray is in compact, concave, fan-shaped masses arranged laterally, producing very interesting horizontal lines and shadows.

E4—*Chamaecyparis pisifera*.

E4—*Chamaecyparis pisifera* var. *filifera*.

E4—*Chamaecyparis pisifera* var. *plumosa*.

E4—*Chamaecyparis pisifera* var. *squarrosa*.

E or S1—*Chamaedaphne calyculata*.

EG1—*Chimaphila maculata*.

EG1—*Chimaphila umbellata*.

4—*Chionanthus virginica*.

V—*Clematis apiifolia*.

V—*Clematis Henryi*.

V—*Clematis Jackmannii*.

V—*Clematis Jackmannii* var. *alba*.

V—*Clematis montana* in variety.

V—*Clematis paniculata*.

V—*Clematis tangutica*.

V—*Clematis texensis* (C. *Viorna* var. *coccinea*).

V—*Clematis virginiana*.

3—*Clethra alnifolia*.

4—*Colutea arborescens*.

1—*Comptonia asplenifolia*.

Cornus (all shrubby *cornuses* are better if kept vigorous by constant thinning and renewal from base).

3—*Cornus alba*.

3—*Cornus alba* var. *sibirica*.

4—*Cornus alternifolia* (small tree or tree-like shrub).

3—*Cornus Amomum* (C. *sericea*).

4—*Cornus florida* (large shrub or small tree, 20 feet).

4—*Cornus florida* var. *rubra* (shrub or small tree, 20 feet).

4—*Cornus mas* (small compact tree, 15 to 20 feet).

3—*Cornus racemosa* (C. *candidissima* and C. *paniculata*).

3—*Cornus rugosa* (C. *circinata*).

3—*Cornus sanguinea* var. *viridissima*.

3—*Cornus stolonifera*.

3—*Cornus stolonifera* var. *flaviramea*.

3—*Corylus americana*.

3—*Corylus Avellana*.

4—*Corylus maxima*.

3—*Corylus rostrata*.

4—*Cotinus Coggygia*.

EeP1—*Cotoneaster adpressa* (6 to 12 inches, slow-growing).

PS2—*Cotoneaster Franchetii* (occasionally larger).

1—*Cotoneaster horizontalis*.

EGP1—*Cotoneaster microphylla* (4 to 6 inches; flatter than C. *adpressa* and better as ground-cover in rock-garden).

2—*Cotoneaster racemiflora*.

2—*Cotoneaster Simonsii*.

2—*Cotoneaster tomentosa*.

H4—*Crataegus coccinea*. All these thorns are better as natural screens with room to spread at the bottom than when confined in restricted hedge lines.

H4—*Crataegus Crus-galli*.

H4—*Crataegus Oxyacantha* var. *Paulii*.

4—*Crataegus Phænoxyprum* (C. *cordata*).

H4—*Crataegus punctata*.

4—*Crataegus tomentosa*.

PS1—*Cytisus hirsutus*.

2—*Cytisus ratisbonensis* (2 to 3 feet).

P2—*Cytisus scoparius*.

- Fe1—*Daphne Cneorum*.
 2—*Daphne Mezereum*.
 2—*Daphne Mezereum* var. *alba*.
 E2—*Daphne pontica*.
 1—*Deutzia gracilis* (2 feet).
 2—*Deutzia Lemoinei* (3 to 4 feet).
 3—*Deutzia scabra* var. *flore-pleno* (Pride of Rochester).
 1—*Diervilla Lonicera*.
 3—*Diervilla hybrida* in variety (Le Printemps is early pink; Eva Rathke is late red).
 H2—*Dirca palustris*. This is a native shrub with flexible leathery twigs, small yellow flowers in early spring, good light green foliage in summer, and yellow color in autumn.
 4—*Elæagnus angustifolia*.
 3—*Elæagnus multiflora* (E. longipes).
 2—*Enkianthus perulatus*.
 E1—*Epigæa repens* (4 inches).
 Ee1—*Erica carnea* (6 inches; flower-buds conspicuous all winter; foliage glossy).
 Ee1—*Erica carnea* var. *alba*.
 Ee1—*Erica Tetralix* (6 inches; summer-blooming; no winter buds visible; foliage grayish).
 H3—*Evonymus alata*.
 4—*Evonymus europæa*.
 G1—*Evonymus obovata* (1 foot).
 EGHV2—*Evonymus radicans* var. *vegeta*. This is the hardiest evergreen vine for brick and stone. It is also used for low mass planting, for hedges and edging, and for ground-cover. The fruit in all varieties is an orange and red berry like that of *Celastrus scandens*. But not all plants fruit, and therefore care should be taken to select stocks from fruiting plants.
 3—*Exochorda racemosa*.
 3—*Forsythia suspensa*. Shrub with recurving stems, excellent for trailing over a bank or hanging down a wall. Has good definite form and therefore the best forsythia for individual specimen planting.
 3—*Forsythia suspensa* var. *Fortunei*.
 3—*Forsythia viridissima*.
 2—*Fothergilla major*.
 EG1—*Gaultheria procumbens*.
 1—*Gaylussacia baccata* (G. resinosa).
 Ee1—*Gaylussacia brachycera*.
 1—*Genista tinctoria*.
 4—*Halesia carolina* (H. tetraptera).
 3—*Halimodendron halodendron*.
 4—*Hamamelis japonica* var. *arborea*.
 4—*Hamamelis mollis*.
 2—*Hamamelis vernalis* (occasionally 6 feet).
 4—*Hamamelis virginiana*.
 EGPV—*Hedera helix*.
 EeG1—*Helianthemum Chamæcistus* (H. vulgare).
 H4—*Hibiscus syriacus*.
 4—*Hippophaë rhamnoides*.
 2—*Hydrangea arborescens* var. *grandiflora*.
 4—*Hydrangea paniculata* var. *grandiflora* (15 feet).
 GV—*Hydrangea petiolaris*.
 1—*Hydrangea quercifolia* (cut to ground annually).
 1—*Hydrangea radiata* (cut to ground annually).
 2—*Hypericum aureum*.
 e1—*Hypericum Buckleii*.
 EGP1—*Hypericum calycinum* (6 inches to 1 foot).
 2—*Hypericum prolificum*.
 Ee1—*Iberis sempervirens* (6 inches).
 Ee1—*Iberis Tenoreana* (6 inches).
 DEHP3—*Ilex orenata*.
 D2—*Ilex decidua*.
 DEH2—*Ilex glabra*.
 DEH4—*Ilex opaca*.
 D3—*Ilex verticillata*.
 1—*Indigofera Kirilowii* (cut to ground annually).
 DEH4—*Juniperus chinensis*. All forms of *Juniperus* in this list are very slow-growing except *J. communis* var. *hibernica*.
 E2—*Juniperus chinensis* var. *erecta*.
 DE3—*Juniperus chinensis* var. *Pfitzeriana*.
 DEeG1—*Juniperus chinensis* var. *procumbens*.
 DE2—*Juniperus communis*.
 DEH4—*Juniperus communis* var. *hibernica*.
 DEG1—*Juniperus communis* var. *montana* (1 foot high).
 DEG1—*Juniperus horizontalis* (J. Sabina var. *procumbens*).
 DEG1—*Juniperus horizontalis* var. *Douglasii*.
 DE3—*Juniperus Sabina*.
 DEe1—*Juniperus Sabina* var. *tamariscifolia* (2 to 3 feet, neat and compact and very slow-growing, with short horizontal branches and upcurving branchlets).
 E1—*Kalmia angustifolia*.
 E3—*Kalmia latifolia* (sometimes higher).
 2—*Kerria japonica*.
 4—*Kœlreuteria paniculata* (round-headed tree 20 to 30 feet high; summer bloomer).
 4—*Laburnum alpinum* (compact shrub or small tree 20 to 30 feet, more hardy than the common *L. vulgare*).
 Ee1—*Leiophyllum buxifolium* var. *prostratum*.
 2—*Lespedeza bicolor*.
 EG1—*Leucothœ Catesbæi* (occasionally 3 feet).
 H4—*Ligustrum Ibotia*.
 H2—*Ligustrum Ibotia* var. *Regelianum*.
 HS2—*Ligustrum ovalifolium*. See remarks on page 2683.
 HS4—*Ligustrum vulgare*, the common privet.

- 4—*Lonicera bella* var. *rosea*.
 3—*Lonicera fragrantissima*.
 V—*Lonicera Heckrottii*.
 SV—*Lonicera Henryi*.
 SV—*Lonicera japonica* var. *Halliana*.
 4—*Lonicera Maackii*.
 3—*Lonicera Morrowii*.
 V—*Lonicera Periclymenum*.
 V—*Lonicera sempervirens*.
 e1—*Lonicera spinosa*.
 4—*Lonicera tatarica*.
 2—*Lonicera thibetica*.
 S2—*Lycium chinense*.
 S2—*Lycium halimifolium* (L. vulgare). These lyciums have same general habit as *Forsythia suspensa*, but are more vigorous. Their branches root easily and the plants may become a nuisance and hard to eradicate. See note on page 2681.

3049. A good shrub ruined by the shears.

- 4—*Magnolia denudata* (M. Yulan) (tree, 30 to 40 feet).
 S4—*Magnolia glauca* (M. virginiana).
 4—*Magnolia Lennei*.
 4—*Magnolia Soulangiana*.
 4—*Magnolia stellata*.
 EP1—*Mahonia Aquifolium* (2 feet).
 EP2—*Mahonia japonica*.
 EG1—*Mahonia repens* (1 foot).
 V—*Menispermum canadense*.
 EG1—*Mitchella repens* (1 to 2 inches; very flat and creeping).
 DS4—*Myrica carolinensis*. Can be kept lower very easily by thinning out and renewing from the base. Is still known in commerce as *M. cerifera*. Ranges north to Nova Scotia near the coast. Is more shrubby, with blunt leaves which are broader and more oblong than those of *M. cerifera*. This latter is a southern plant, closely related but probably tender in New England. It is more tree-like, with pointed leaves which are narrower and more lanceolate than those of *M. carolinensis*.
 1—*Myrica Gale*.
 2—*Neviusia alabamensis*.
 4—*Oxydendrum arboreum*.
 EeP1—*Pachistima Canbyi* (4 to 5 inches).
 EP1—*Pachistima myrsinites* (1-2 feet).
 EeG1—*Pachysandra terminalis* (6 inches to 1 foot).
 1—*Pæonia suffruticosa* (P. Moutan).
 V—*Parthenocissus quinquefolia*.
 V—*Parthenocissus tricuspidata*.
 3—*Philadelphus coronarius* (often 10 feet).
 1—*Philadelphus coronarius* var. *nanus* (2 to 3 feet; very dense and compact; seldom has flowers).
 3—*Philadelphus inodorus*.
 4—*Philadelphus pubescens* (P. grandiflorus or P. latifolius).
 2—*Philadelphus Lemoinei* (in variety, especially vars. *Avalanche*, *Candelabra*, and *Gerbe de Neige*).
 2—*Philadelphus microphyllus* (this and *P. coronarius* are the original parents of the *Lemoinei* hybrids).
 4—*Photinia villosa*.
 3 or 4—*Physocarpus opulifolius*.
 Ee1—*Picea excelsa* dwarf varieties, as var. *Cianbraziliana* (2 to 3 feet) and var. *Maxwellii* (1 foot).
 Ee1—*Picea mariana* var. *Doumettii* (1 foot).
 EH—*Picea orientalis*. This is a large tree but is adapted to small-scale planting because very slow-growing and also because easily restrained. Foliage small, blunt, and dark glossy green.
 E2—*Pieris floribunda* (2 to 3 feet).
 EP2—*Pieris japonica*.
 2—*Pieris mariana* (2 to 3 feet).
 E2—*Pinus densiflora* var. *pumila*.
 E4—*Pinus montana* (a low bushy tree 20 feet high and 20 feet broad; very slow-growing).
 E2—*Pinus montana* var. *Mughus*.
 V—*Polygonum baldschuanicum*.
 2—*Potentilla fruticosa* (2 to 3 feet).
 eS1—*Potentilla tridentata* (6 inches).
 EGP1—*Prunus Laurocerasus* var. *schipkaensis*.
 2—*Prunus maritima*.

- 2—*Prunus pumila*.
 3—*Prunus tomentosa*.
 3—*Prunus triloba* var. *flore-pleno*.
 4—*Ptelea trifoliata*.
 EeHP1—*Pyracantha coccinea* var. *pauciflora* (plant low, dense, and thorny).
 4—*Pyrus coronaria*.
 4—*Pyrus Halliana*.
 4—*Pyrus ioensis*, Bechtel's variety.
 4—*Pyrus pulcherrima* (small tree).
 4—*Quercus ilicifolia* (Q. nana).
 H4—*Rhamnus cathartica*.
 2—*Rhamnus fallax*.
 4—*Rhamnus Frangula*.
 EeHP1—*Rhododendron amcenum*.
 3—*Rhododendron arborescens*.
 E1—*Rhododendron arbutifolium* (R. Wilsonii).
 E2—*Rhododendron*, *Boule de Neige* (white, early).
 3—*Rhododendron calendulaceum*.
 E2—*Rhododendron caractacus* (bright red, bloom medium).
 E2—*Rhododendron carolinianum* (R. punctatum in part).
 This is a low, compact rhododendron native to the high mountains of North Carolina, with broad leaves and early rose-pink flowers in late May before the new leaves appear. It was placed on the market under the name R. punctatum. The real R. punctatum is a taller looser-growing shrub, native to lower altitudes from North Carolina south, with narrower leaves, and flowers that bloom a month later than those of R. carolinianum and are more or less overtopped and obscured by new leaf-growth. The old R. punctatum is now called R. minus. (See Rhodora, vol. 14, No. 162, June, 1912.)
 E3—*Rhododendron catawbiense* var. *album* (this has same compact habit as R. catawbiense, but flowers are white instead of magenta, early.).
 E3—*Rhododendron delicatissimum* (blush-white, late).
 E3—*Rhododendron Everestianum* (lavender, early).
 EeHP1—*Rhododendron Hindogiri*.
 E3—*Rhododendron*, H. W. Sargent (red, late).
 3—*Rhododendron Kaempferi*.
 E3—*Rhododendron*, Lady Armstrong (pink, early to medium).
 E4—*Rhododendron maximum*.
 2—*Rhododendron mucronulatum*.
 EeH1—*Rhododendron myrtifolium*.
 2—*Rhododendron nudiflorum*.
 E3—*Rhododendron purpureum elegans* (purple, bloom medium).
 3—*Rhododendron Vaseyi*.
 2—*Rhododendron viscosum*.
 3—*Rhodotypos kerrioides*.
 G2—*Rhus canadensis* (R. aromatica).
 4—*Rhus copallina*.
 4—*Rhus glabra*.
 4—*Rhus hirta*.
 4—*Rhus typhina* (R. hirta).
 2—*Ribes alpinum*.
 2—*Ribes cereum*.
 3—*Ribes odoratum* (R. aureum) (Buffalo, Flowering, or Missouri Currant).
 2—*Ribes pinetorum*.
 2—*Robinia hispida*.
 2—*Robinia Kelseyi*.
 2—*Rosa carolina*.
 2—*Rosa cinnamomea*.
 2—*Rosa Harisonii*.
 2—*Rosa multiflora* (5 to 6 feet or higher).
 1—*Rosa nitida* (2 ft.).
 2—*Rosa rubiginosa*.
 2—*Rosa rugosa*.
 2—*Rosa rugosa* var. *Blanche de Coubert* (beautiful semi-double white).
 2—*Rosa setigera* (2 to 4 feet).
 2—*Rosa spinosissima* var. *altaica* (often 5 feet).
 1—*Rosa virginiana* (R. lucida) (2 feet).
 GS1V—*Rosa wichuraiana* (1 foot).
 2—*Rubus allegheniensis*.
 2—*Rubus crataegifolius*.
 GS1—*Rubus hispidus* (6 inches).
 2—*Rubus occidentalis*.
 2—*Rubus odoratus*.
 GS1—*Rubus spectabilis* var. *plena* (R. Linkianus or R. ulmi-folius) (18 inches).
 G1—*Rubus procumbens* (R. villosus) (12 inches).
 4—*Salix Caprea*.
 4—*Salix cordata*.
 4—*Salix discolor*.

3050. One value of the shrub lies in its bloom.—*Clethra alnifolia*

- 2—*Salix humilis* (sometimes reaches 6 to 8 feet).
 4—*Salix purpurea*.
 e1—*Salix tristis* (1 foot to 18 inches).
 3—*Sambucus canadensis* (sometimes over 10 feet).
 3—*Sambucus racemosa*.

3051. *Deutzia Lemoinei*.

- GV—*Schizophragma hydrangeoides*.
 4—*Shepherdia argentea*.
 2—*Shepherdia canadensis*.
 V—*Smilax glauca*.
 V—*Smilax rotundifolia*.
 3—*Sophora viciifolia* (new plant from China; will probably grow 10 feet under cultivation).
 2—*Sorbaria Aitchisonii* (this plant is very handsome, but tender at Boston).
 2—*Sorbaria arborea* (most handsome hardy sorbaria).
 2—*Sorbaria sorbifolia*.
 2—*Spiraea alba* (S. salicifolia).
 2—*Spiraea arguta*.
 3—*Spiraea Billardii* (S. Lenneana).
 3—*Spiraea bracteata*.
 eH1—*Spiraea Bumalda*, Anthony Waterer variety (2 feet).
 3—*Spiraea crenata*.
 3—*Spiraea Douglasii*.
 3—*Spiraea gemmata*.
 2—*Spiraea japonica* (S. callosa) (3 feet).
 3—*Spiraea prunifolia* var. *flore-pleno*.
 2—*Spiraea salicifolia* (S. alba).
 2—*Spiraea Thunbergii*.
 2—*Spiraea tomentosa*.
 2—*Spiraea trilobata*.
 3—*Spiraea Van Houttei*.
 3—*Staphylea Bumalda*.
 3—*Staphylea trifoliata* (sometimes 12 feet high).
 2—*Stephanandra incisa*.
 2—*Stephanandra Tanakae*.
 4—*Stewartia Pseudo-camellia*.
 4—*Styrax japonica*.
 2—*Symphoricarpos albus*.
 2—*Symphoricarpos orbiculatus* (2 to 3 feet).
 4—*Symplocos crataegoides*.
 4—*Syringa chinensis* (S. rothomagensis) var. *alba*.
 4—*Syringa chinensis* (S. rothomagensis) var. *rubra*.
 4—*Syringa japonica* (small compact tree, to 30 feet).
 4—*Syringa oblata*.
 4—*Syringa persica* var. *alba*.
 4—*Syringa persica* var. *rubra*.
 4—*Syringa villosa*.
 H4—*Syringa vulgaris* (there are many color varieties).
 3—*Tamarix*.
 De1—*Taxus baccata* var. *repandens*.
 DG1—*Taxus canadensis* (good in shade but not so satisfactory as other forms in full sun).
 DH3—*Taxus cuspidata*.
 DH2—*Taxus cuspidata* var. *nana*.
 EH4—*Thuja occidentalis* (dense pyramidal tree; very slow-growing, but may reach 50 to 60 feet in time).
 EeH1—*Thuja occidentalis* var. *nana* (this may reach 3 to 4 feet, but is very slow-growing and easily restrained by clipping).
 EH4—*Thuja orientalis*. More handsome than our native arbovitae. The branches and branchlets are more distinctly vertical and the foliage is smaller and brighter green.
 EeH1—*Thuja orientalis* var. *Sieboldii* or *nana* (this may reach 3 to 4 feet, but is very slow-growing and is easily restrained by clipping).
 EeG1—*Thymus Serpyllum* (4 to 5 inches).
 EH 3 or 4—*Tsuga canadensis*. The most graceful and effective evergreen tree for mass-planting. Takes up less room than white pine and is much slower-growing. Can be restrained easily and therefore is adapted to hedge and small-scale plantings.
 2—*Vaccinium corymbosum*.
 eG1—*Vaccinium pennsylvanicum* (1 foot).
 1—*Vaccinium vacillans*.
 2—*Viburnum acerifolium*.
 2—*Viburnum alnifolium* (V. lantanoides).
 4—*Viburnum americanum*.
 2—*Viburnum Carlesii* (first viburnum to flower, and very fragrant; buds are pink before opening; new plant from Korea).

- 3—*Viburnum cassinoides*.
H3 or 4—*Viburnum dentatum* (will reach 10 to 12 feet, but may be restrained easily by gradual renewal from the base).
3—*Viburnum dilatatum*.
H4—*Viburnum Lantana*.
4—*Viburnum Lentago*.
4—*Viburnum Opulus*.
1—*Viburnum Opulus* var. *nanum* (2 to 3 feet, very dense and compact; seldom has flowers).
4—*Viburnum Opulus* var. *sterile*.
H4—*Viburnum prunifolium*.
3—*Viburnum pubescens*.
EP2—*Viburnum rhytidophyllum*. Grows to 10 feet in China but needs protection in Boston and Rochester either by artificial covering or special location providing shade from the winter sun. Even when so protected the flower-buds are usually killed just like those of *Andromeda japonica*.
4—*Viburnum Sieboldii*.
3—*Viburnum tomentosum* (sometimes larger).
3—*Viburnum tomentosum* var. *plenum*.
H3 or 4—*Viburnum venosum* (*V. molle*). Similar to *V. dentatum* but more vigorous with broader leaves, rougher twigs and later bloom. Will grow to 12 feet but easily restrained by gradual renewal from the base.
3—*Viburnum Wrightii*.
EeG1—*Vinca minor*.
3—*Vitex incisa*.
V—*Vitis Coignetiae*.
V—*Wisteria chinensis*.
V—*Wisteria chinensis* var. *alba*.
G1—*Xanthorrhiza apiifolia*.
1—*Yucca angustifolia*.
1—*Yucca filamentosa*.
S2—*Zenobia pulverulenta* (foliage and twigs blue-gray; very handsome).

RALPH W. CURTIS.

Shrubs for the Middle West.

The most popular shrubs in the Middle West, as in any new country, are usually of foreign origin. However, the native shrubs are beginning to play a great part in restoring and intensifying the characteristic beauty of this region. The dominant feature of middle western shrubbery is not apparent to all. This is largely due to the fact that the Middle West contains no unique species that compel universal admiration like the mountain laurel and rhododendrons, which are the crowning glory of the East. Every shrub of importance native to the Middle West is also native to the East. While the Middle West may rival the East in the luxuriance of its shrubbery, it is poorer in species, both native and foreign. About two-fifths of the middle western shrubs that are in general cultivation bear their flowers in flat clusters. These have been called "symbols of the prairie" since they repeat many times on a small scale the great line of the horizon, which is the strongest feature of the middle western scenery, whether wild or cultivated, treeless or forested. Repetition of the horizontal is conspicuous enough wherever hawthorns and prairie crab-apples (*Pyrus ioensis*) are abundant, owing to their strong horizontal branching. Few shrubs, however, have stratified branches. Their suggestion of the prairie is subtler and less insistent, because it appears only in the bloom. The boldest repeater of the prairie among the shrubs is the American black elder, with clusters 6 to 8 inches across. The viburnums and dogwoods have smaller clusters, ranging from 5 inches in diameter down to 2 inches. When wood and prairie meet, the prairie note is sounded more strongly by shrubs with horizontal branches, especially witch-hazel, and by juneberry and gray dogwood which, though

3052. *Sambucus canadensis*.

erect when young, become intensely stratified when old. This is an important part of the prairie style of landscape gardening. The following lists are therefore classified according to this idea.

Stratified shrubs. (Those marked * have horizontal branches, at least when old. The others have flat clusters of flowers.)

Low shrubs, suitable for foundation planting and edging borders: *Ceanothus americanus* and *C. ovatus*; *Hydrangea arborescens*; *Viburnum acerifolium* and *V. pubescens*.

3053. *Spiraea Van Houttei*.

Medium-high shrubs, ordinarily 5 to 6 feet: *Cornus Amomum*, *C. racemosa** (or *C. paniculata*), and *C. stolonifera*; *Sambucus pubens*, *S. canadensis*, and its var. *acutiloba*; *Viburnum cassinoides*, *V. dentatum*, *V. molle*, and *V. americanum*. The last-named is considered by botanists to be the same as the European *V. Opulus*, but the American form is considered to be freer from plant-lice and is superior in other ways.

Tall shrubs, suitable for the back of a border, corner of a house, or high foundation: *Aralia spinosa**; *Cornus alternifolia** and *C. rugosa** (or *C. circinata*); *Hamamelis virginiana**; *Physocarpus opulifolius*; *Viburnum Lentago* and *V. prunifolium*.

Non-stratified shrubs.

Low shrubs: *Amelanchier alnifolia* and var. *pumila*; *Diervilla trifida*; *Evonymus obovata*; *Prunus pumila*; *Rhus canadensis* (or *R. aromatica*); *Ribes americanum*; *Rosa virginiana* (or *R. blanda*), *R. carolina*, *R. humilis*, and *R. setigera*; *Rubus hispids*; *Symphoricarpos occidentalis* and *S. orbiculatus*.

Medium-high shrubs: *Corylus americana*; *Evonymus americana*; *Ilex verticillata*; *Rhus copallina*, *R. glabra*, and *R. typhina*; *Ribes aureum* and *R. cynosbati*; *Spiraea alba*; *Symphoricarpos albus*.

Tall shrubs: *Aronia arbutifolia* and *A. melanocarpa*; *Benzoin zestivale*; *Cephalanthus occidentalis*; *Staphylea trifolia*; *Zanthoxylum americanum*.

The most significant plants in the above list, probably, are sumac and prairie rose. The sumac (*Rhus glabra*) was undoubtedly the most virile note on the wild prairie, where the summer foliage took on a wonderful gloss. It is still the most gorgeous color in the corn-belt, where brilliant reds are not commonly developed in autumn. The prairie rose, also known as the Michigan or Illinois rose (*Rosa setigera*), is now much planted beside front doors. The common wild rose of the open prairie is *Rosa humilis*, which, however, is familiar in the East, while *Rosa setigera* is decidedly more western in its range.

The middle western point of view may be indicated by brief notes on a few other species. *Ceanothus ovatus* is thought to be more refined in cultivation than New Jersey tea and has more "western color;" should combine well with *Lilium canadense* or *L. superbum*. *Cornus racemosa* has been called "sunset dogwood" because in autumn its countless red pedicels make a glow like the characteristic prairie sunset; this and

sumac are prominent in "sunset gardens." *Cornus rugosa* is a magnificent species, but must have shade. Although hazel (*Corylus*) may be considered "coarse" in the East, its rugged character pleases the Middle West and its autumn color is unique. *Hamamelis virginiana* is very popular because its yellow foliage lights up the autumn woods and because its stratified branches carry the prairie spirit into the woodland. *Sambucus pubens*, the red elder, will not thrive on clay or in full sun; it wants shade and prefers sandy soil. *Symphoricarpos*

3054. Gardenia.

carpos orbiculatus is commonly called "buckbush," and is a familiar sight in pastures. *Viburnum acerifolium* is useful for the shady side of the house. *Viburnum pubescens* is the most floriferous of the viburnums and formerly common near Chicago. *Zanthoxylum americanum* is almost as common in woodlots as buckbush; the scent of the foliage generally pleases.

WILHELM MILLER.

Shrubs for street and park planting.

Eastern United States, northern section.

Berberis Thunbergii.
Ceanothus americana.
Cercis canadensis.
Cercis japonica.
Chenomeles japonica (subject to San José scale).
Clethra alnifolia.
Cornus in variety (these are subject to scale insects).
Forsythia Fortunei.
Forsythia viridissima.
Hydrangea arborescens.
Hydrangea paniculata.
Kerria japonica.
Ligustrum Iboia.
Ligustrum Iboia var. *Regelianum*.
Lonicera Morrowii.
Lonicera tatarica.
Philadelphus in variety.
Physocarpus opulifolius.
Rhodotypos kerrioides.
Ribes in variety.
Rosa rugosa and other species.
Spiraea Billardii.
Spiraea Bumalda, including var. *Anthony Waterer*.
Spiraea japonica.
Spiraea japonica var. *alba*.
Spiraea carpinifolia.
Spiraea Van Houttei.
Symphoricarpos albus.
Symphoricarpos orbiculatus.
Syringa in variety.
Tamarix in variety (may be killed to the ground in the extreme North but will come again from the root).
Viburnum dentatum.
Viburnum Opulus.

Eastern United States, central section. (From Philadelphia and St. Louis southward, in addition to the shrubs for the northern section.)

Abelia grandiflora.
Buddleia variabilis varieties.
Callicarpa purpurea.
Caryopteris incana.
Deutzia in variety.
Evonymus in variety.
Forsythia suspensa.
Hypericum Moserianum.
Ilex in variety.
Jasminum in variety.
Ligustrum in variety.
Mahonia Aquifolium.
Spiraea in variety.
Staphylea pinnata.
Staphylea trifolia.
Stephanandra incisa.
Styrax japonica.

Eastern United States, southern section. (For use in addition to the two foregoing lists for points south of Wilmington, North Carolina, and Charleston, South Carolina, and westward in the southern half of the states on the Gulf of Mexico.)

Aucuba japonica.
Gardenia in variety.
Nerium Oleander.
Osmanthus Aquifolium.
Pittosporum Tobira.
Prunus caroliniana.
Prunus Laurocerasus.
Viburnum Tinus.

Shrubs for the seashore.

Berberis Thunbergii.
Hibiscus syriacus.
Hydrangea, both woody and semi-herbaceous.
Ilex opaca.
Juniperus virginiana.
Ligustrum in variety.
Myrica cerifera.
Rosa nitida.
Rosa rugosa.
Rosa Wichuraiana.
Spiraea in variety.
Symphoricarpos albus.
Symphoricarpos orbiculatus.
Tamarix in variety.

The ilex, the hibiscus, and some of the ligustrums will not be hardy on the extreme northern Atlantic seacoast but will be hardy much farther north on the shore than in the regions adjoining.

Shrubs for regions of little rainfall.

Berberis Thunbergii.
Eleagnus, especially *E. angustifolia*.
Lonicera, especially *L. Morrowii* and *L. tatarica*.
Philadelphus Lewisii.
Prunus serotina.
Ribes, especially *R. aureum*.
Rosa arkansana of cult.
Rosa caroliniana var. *lucida*.
Rosa nitida.
Rosa rugosa.
Rosa setigera.
Spiraea in variety.
Symphoricarpos in variety.
Syringa, especially *S. chinensis*.
Tamarix in variety.

In the northern sections the tamarix will kill to the ground every winter but will come from the root. The tender spireas should not be used north of Denver, Colorado.

Shrubs for the Pacific slope. (In addition to the plants suggested for the eastern United States. The lists for both the northern and central sections of the eastern states may be used on the North Pacific slope and all the eastern lists for the southern sections.)

Arbutus Unedo.
Ceanothus thyrsiflorus and other native species.
Cotoneaster in variety.
Crataegus in variety, especially *C. Pyracantha* (*Pyracantha* *coccinea*).
Eleagnus in variety.
Evonymus in variety.
Sambucus racemosa.
Spartium junceum.
Spiraea arifolia and others.
Veronica in variety.

Shrubs for the Southern section. (In addition to all these listed for the eastern United States and the above.)

Eseallonia in variety.
Photinia arbutifolia.
Pittosporum in variety.
Prunus ilicifolia.
Prunus integrifolia.

F. L. MULFORD.

Shrubs for midcontinental region.

The following list of shrubs for the most part consists of kinds known to be perfectly hardy and to succeed in the region of St. Louis if planted with usual care and subsequently given reasonably good treatment. Many choice sorts which are not likely to be hardy much north of central Missouri without some protection are indicated by an asterisk (*). A few may not be generally known to the trade and hence procured with some difficulty at present but their value for this region was demonstrated by being grown several years at the Missouri Botanical Garden. Azalea and certain other Ericaceæ, together with some allied genera like *Kalmia* that have formed attractive features in many plantations, are not included because they are generally short-lived and require more than ordinary care in planting and subsequent handling.

**Acanthopanax pentaphyllum*.
Æsculus parviflora.
Alnus Mitchelliana.
Alnus serrulata.
Amelanchier canadensis.
**Amorpha canescens*.
Amorpha fruticosa.
Aronia arbutifolia.
**Baccharis halimifolia*.
**Benzoin estivale*.
Berberis Thunbergii.
Berberis vulgaris.
Berberis vulgaris var. atropurpurea.
Betula nana.
Betula pumila.
**Buddleia Davidii*.
Buddleia Lindleyana.
Calycanthus fertilis.
Calycanthus floridus.
**Calycanthus occidentalis*.
Caragana arborescens.
**Caryopteris incana*.
**Ceanothus americanus*.
Cephalanthus occidentalis.
Cercis canadensis.
Chenomeles japonica.
Clethra alnifolia.
**Colutea arborescens*.
**Comptonia asplenifolia*.
Cornus alba.
Cornus alba var. sibirica.
Cornus alternifolia.
Cornus Amomum.
Cornus mas.
Cornus racemosa.
Cornus rugosa.
Cornus sanguinea.
Cornus stolonifera.
Cornus stolonifera var. flaviramea.
**Coronilla Emerus*.
Corylus americana.
Corylus Avellana var. atropurpurea.
Corylus Avellana var. laciniata.
Cotinus Coggygia.
**Cotoneaster acuminata*.
**Cotoneaster racemiflora*.
Crataegus Crus-galli.
Crataegus Oxyacantha.
**Daphne Mezereum*.
Deutzia gracilis.
Deutzia Lemoinei.
Deutzia scabra.
Deutzia scabra, "Pride of Rochester".
Deutzia scabra var. Watereri.
Diervilla floribunda.
Diervilla floribunda var. grandiflora.
Diervilla hybrida, "Eva Rathke".
Diervilla hybrida Kosteriana variegata.
Diervilla Lonicera.
Dirca palustris.
Elæagnus angustifolia.
Elæagnus argentea.
Elæagnus multiflora.
Elæagnus umbellata.
**Evonymus alata*.
Evonymus americana.
Evonymus atropurpurea.
Evonymus Bungeana.
Evonymus europæa.
Evonymus obovata.
**Evonymus radicans*.
**Evonymus radicans var. vegeta*.
**Exochorda racemosa*.
Forsythia intermedia.
Forsythia suspensa.
Forsythia viridissima.
Halimodendron halodendron.
Hamamelis virginiana.
Hibiscus syriacus, in variety.
Hibiscus syriacus var. Meehanii.
**Hippophaë rhamnoides*.
Hydrangea arborescens var. grandiflora.
Hydrangea paniculata.
Hydrangea paniculata var. grandiflora.
**Hydrangea quercifolia*.
**Hypericum Moserianum*.
**Ilex decidua*.
**Ilex serrata*.
**Ilex verticillata*.

**Itea virginica*.
**Kerria japonica*.
**Kerria japonica argenteo-variegata*.
**Laburnum anagyroides*.
**Lespedeza bicolor*.
**Lespedeza Sieboldii*.
Ligustrum amurense.
Ligustrum Iboata var. Regelianum.
**Ligustrum ovalifolium*.
**Lonicera fragrantissima*.
Lonicera involucrata.
Lonicera Ledebourii.
Lonicera Morrowii.
Lonicera Ruprechtiana.
Lonicera Standishii.
Lonicera tatarica.
Lonicera tatarica var. grandiflora.
Lonicera tatarica var. latifolia.
Lonicera tatarica var. punicata.
Lycium chinense.
Lycium halimifolium.
**Magnolia Soulangeana*.
**Magnolia Soulangeana var. Lenei*.
**Magnolia Soulangeana var. speciosa*.
**Magnolia stellata*.
Mahonia Aquifolium.
Philadelphus coronarius.
Philadelphus coronarius var. flore-pleno.
Philadelphus inodorus.
Philadelphus laxus.
Philadelphus Lemoinei.
Philadelphus Lemoinei var. erectus.
Philadelphus pubescens.
Physocarpus opulifolius.
Physocarpus opulifolius var. lutea.
Potentilla fruticosa.
Prunus Amygdalus, and white variety.
Ptelea trifoliata.
**Rhamnus alnifolia*.
Rhamnus caroliniana.
Rhamnus cathartica.
Rhamnus Frangula.
**Rhodotypos kerrioides*.
Rhus canadensis.
Rhus copallina.
Rhus glabra.
Rhus glabra var. laciniata.
Rhus typhina.
Rhus typhina var. laciniata.
Ribes aureum.
Ribes Gordonianum.
Ribes sanguineum.
Robinia hispida.
Rubus odoratus.
Salix discolor.
Salix humilis.
Salix pentandra.
Salix petiolaris.
Salix purpurea.
Salix rostrata.
Salix sericea.
Salix tristis.
Sambucus canadensis.
Sambucus nigra.
Sambucus nigra var. aurea.
Sambucus nigra var. laciniata.
Sambucus racemosa.
Shepherdia argentea.
Sorbus melanocarpa.
Spiræa arguta.
Spiræa Billardii.
Spiræa Bumalda.
Spiræa Bumalda, "Anthony Waterer".
Spiræa Menziesii.
Spiræa prunifolia.
Spiræa prunifolia var. flore-pleno.
Spiræa salicifolia.
Spiræa Thunbergii.
Spiræa Van Houttei.
Staphylea colchica.
Staphylea trifolia.
**Stephanandra incisa*.
Syringa persica.
Syringa villosa.
Syringa vulgaris, in variety.
Symphoricarpos albus.
Symphoricarpos orbiculatus.
Tamarix africana.
Tamarix gallica.

Tamarix gallica indica.
Tamarix hispida estivalis.
Tamarix tetrandra purpurea.
Viburnum acerifolium.
Viburnum cassinoides.
Viburnum dentatum.
Viburnum Lantana.
Viburnum Lentago.

Viburnum molle.
Viburnum Opulus.
Viburnum Opulus var. sterile.
Viburnum tomentosum.
Viburnum prunifolium.
**Vitex Agnus-castus*.
Xanthoceras sorbifolia.
**Xanthorrhiza apifolia*.

3055. *Hydrangea paniculata* var. *grandiflora*.

A few species commonly classed as woody are more herbaceous than most shrubs and hence more tender; top should be cut to the ground each spring and treated more as hardy perennials. Among these are the following:

Buddleia Davidii.
Buddleia Lindleyana.
Caryopteris incana.
Coronilla Emerus.

Lespedeza bicolor.
Stephanandra incisa.
Vitex Agnus-castus.

Trailing and climbing vines.

**Actinidia arguta*.
**Akebia quinata*.
**Ampelopsis heterophylla var. amurensis*.
Aristolochia macrophylla.
**Aristolochia tomentosa*.
**Bignonia capreolata*.
Campsis radicans.
Celastrus orbiculatus.
Celastrus scandens.
Clematis Flammula.
Clematis lanuginosa var.
Clematis Jackmanii. [Henryi].
Clematis paniculata.
Clematis virginiana.
**Evonymus radicans*.
**Evonymus radicans var. vegeta*.
Forsythia suspensa.

Lonicera Caprifolium.
**Lonicera japonica*.
**Lonicera japonica var. aureoreticulata*.
**Lonicera japonica var. Halliana*.
Lonicera Periclymenum var. belgica.
Lonicera sempervirens.
Parthenocissus quinquefolia.
Parthenocissus quinquefolia var. Engelmannii.
Parthenocissus tricuspidata.
**Periploca græca*.
Vitis, native species.
Wisteria chinensis.
Wisteria magnifica.
Wisteria speciosa.

Shrubs suitable for hedges.

Berberis Thunbergii.
Berberis vulgaris.
Berberis vulgaris var. atropurpurea.
Deutzia all species listed.
Elæagnus multiflora.
Forsythia intermedia.
Hibiscus syriacus in variety.
**Hippophaë rhamnoides*.
Ligustrum, all listed species.

Shrubs for shady places.

Berberis Thunbergii.
Berberis vulgaris.
Berberis vulgaris var. atropurpurea.
Ceanothus americanus.
Clethra alnifolia.
Cornus, all species.
Deutzia gracilis.
Deutzia Lemoinei.
Forsythia, all species.

Hydrangea arborescens.
Hypericum Moserianum.
Ligustrum, all species.
Lonicera Periclymenum.
Rhus canadensis.
Ribes sanguinea.
Rubus odoratus.
Viburnum acerifolium.
Viburnum dentatum.
Viburnum tomentosum.

Shrubs with twigs of striking color.

Cornus alba var. cerifera.
Cornus sanguinea.
Cornus stolonifera.
Cornus stolonifera var. flaviramea.

Kinds with more or less conspicuous berries.

Berberis Thunbergii.
Berberis vulgaris.

**Evonymus alata*.
Evonymus americana.

Evonymus Bungeana.
Evonymus radicans var.
vegeta.
Ilex verticillata.
Ligustrum amurense.
Ligustrum Iibota var. *Regeli-*
anum.
 **Ligustrum ovalifolium.*
Lonicera Ledebourii.
Lonicera Morrowi.
Lonicera Ruprechtianum.

Rhamnus cathartica
Rhamnus Frangula.
Rhus glabra.
Rhus typhina.
Sambucus, all species listed.
Sorbus arbutifolia.
Sorbus melanocarpa.
Staphylea trifolia.
Symphoricarpos albus.
Symphoricarpos orbiculatus.
Viburnum.

H. C. IRISH.

Shrubs and climbers for the South.

Owing to the great diversity of soil, elevation, and climatic conditions found in the Mountain, Piedmont, and Coastal zones of the South, it is impossible to make or to give an absolutely accurate list of deciduous and broad-leaved shrubs and climbers adapted to the three above-mentioned zones. The planter must, therefore, make due allowances for local conditions.

1. *Piedmont Zone* extends from the Mountain Zone to the Fall Line, which follows approximately the following cities: Weldon and Raleigh, North Carolina, Camden, and Columbia, South Carolina; Augusta, Milledgeville, Macon, and Columbus, Georgia; Montgomery, Alabama; Columbus and Holly Springs, Mississippi.

Deciduous shrubs for the Piedmont Zone.

Acanthopanax pentaphyllum.
Acer japonicum.
Esculus octandra.
Amelanchier atropurpurea.
Amelanchier canadensis.
Amelanchier rotundifolia.
Amorpha canescens.
Amorpha fruticosa.
Amorpha glabra.
Amorpha tennesseensis.
Aralia chinensis var. *mandshur-*
ica.
Aronia arbutifolia.
Aronia melanocarpa.
Azalea arborescens.
Azalea gandavensis.
Azalea lutea.
Azalea mollis.
Azalea nudiflora.
Azalea pontica.
Azalea Vaseyi.
Azalea viscosa.
Baccharis halimifolia.
Benzoin aestivale.
Berberis aristata.
Berberis asiatica.
Berberis canadensis.
Berberis heteropoda.
Berberis Sieboldii.
Berberis sinensis.
Berberis Thunbergii.
Berberis vulgaris.
Berberis vulgaris var. *atro-*
purpurea.
Buckleya distichophylla.
Buddleia Davidii.
Buddleia Davidii var. *mag-*
nifica.
Buddleia intermedia.
Buddleia japonica.
Buddleia Lindleyana.
Buddleia officinalis.
Cassalpinia Gilliesii.
Callicarpa americana.
Callicarpa purpurea.
Calycanthus fertilis.
Calycanthus florida.
Calycanthus occiden-
talis.
Caragana arborescens.
Caragana Chanalagu.
Caryopteris incana.
Cassia macrantha.
Ceanothus americanus.
Ceanothus hybridus.
Cephalanthus occiden-
talis.
Cercis chinensis.
Cercis Siliquastrum.
Chenomeles japonica.
Chilopsis saligna.
Clerodendron trichoto-
mum.
Clethra alnifolia.

Colutea arborescens.
Comptonia asplenifolia.
Cornus alba.
Cornus alba var. *Spaethii.*
Cornus Amomum.
Cornus Mas.
Cornus racemosa.
Cornus rugosa.
Cornus sanguinea.
Cornus stolonifera.
Cornus stolonifera var. *flavi-*

Spiraea revirescens.
Spiraea Schinabeckii.
Spiraea Thunbergii.
Spiraea tomentosa.
Spiraea trilobata.
Spiraea Van Houttei.
Spiraea virginiana.
Staphylea Bumalda.
Staphylea colchica.
Staphylea pinnata.
Staphylea trifolia.
Stephanandra incisa.
Stewartia pentagyna.
Styrax americana.
Styrax japonica.
Styrax Obassia.
Symphoricarpos albus.
Symphoricarpos microphyllus.
Symphoricarpos occidentalis.
Symphoricarpos orbiculatus.
Syringa chinensis.
Syringa Josikea.
Syringa pekinensis.
Syringa persica.

Vines for the Piedmont Zone.

Actinidia arguta.
Actinidia chinensis.
Actinidia Kolomitka.
Akebia lobata.
Akebia quinata.
Ampelopsis arborea.
Antigonon leptopus.
Aristolochia macrophylla.
Berchemia racemosa.
Bignonia capreolata.
Campsis chinensis.
Campsis hybrida.
Campsis, Mme. Gallen.
Campsis radicans.
Celastrus orbiculatus.
Clematis apiifolia.
Clematis crispa.
Clematis Flammula.
Clematis hybrida.
Clematis texensis.
Clematis Viorna.
Clematis virginiana.
Decumaria barbara.
Dioscorea Batatas.
Elæagnus reflexa.
Evonymus radicans.
Evonymus radicans var. variegata.
Evonymus radicans var. vegeta.
Ficus pumila.
Gelsemium sempervirens.
Gelsemium sempervirens flore-pleno.
Hedera canariensis.
Hedera helix.
Humulus Lupulus.
Hydrangea petiolaris.

Broad-leaved evergreens for the Piedmont Zone.

Abelia floribunda.
Abelia grandiflora.
Arbutus Unedo.
Ardisia crenulata var. rubra.
Aucuba japonica.
Aucuba japonica var. latimaculata.
Azalea amena.
Azalea indica.
Azalea indica Kaempferi (Sargent's hybrida).
Azalea obtusa.
Berberis buxifolia.
Berberis Darwinii.
Berberis hakeoides.
Berberis ilicifolia.
Berberis Neubertii.
Berberis Sargentiana.
Berberis stenophylla.
Buxus japonica var. aurea.
Buxus sempervirens.
Buxus sempervirens var. Handworthii.
Buxus sempervirens var. suffruticosa.
Callistemon lanceolatus.
Calluna vulgaris.
Calluna vulgaris var. alba.
Camellia japonica.
Cleyera ochnacea.
Cotoneaster horizontalis.
Cotoneaster microphylla.
Cotoneaster microphylla var. glacialis.
Cotoneaster rotundifolia.

Syringa villosa.
Syringa vulgaris.
Tamarix gallica.
Tamarix gallica var. indica.
Tamarix juniperina.
Tamarix odesana.
Tamarix parviflora.
Vaccinium arboreum.
Vaccinium corymbosum.
Viburnum dentatum.
Viburnum dilatatum.
Viburnum Lantana.
Viburnum macrocephalum.
Viburnum macrocephalum var. sterile.
Viburnum nudum.
Viburnum Opulus.
Viburnum Opulus var. nanum.
Viburnum Opulus var. sterile.
Vitex Agnus-castus.
Vitex incisa.
Xanthorrhiza apiifolia.
Zenobia speciosa.

Kadsura japonica.
Lonicera americana.
Lonicera chinensis.
Lonicera flava.
Lonicera glaucescens.
Lonicera Heckrottii.
Lonicera japonica.
Lonicera japonica var. aureo-reticulata.
Lonicera Periclymenum var belgica.
Lonicera prolifera.
Lonicera sempervirens.
Lonicera Vilmorinii.
Menispermum canadense.
Parthenocissus Henryana.
Parthenocissus quinquefolia.
Parthenocissus quinquefolia var. Engelmannii.
Parthenocissus tricuspidata var. Veitchii.
Passiflora cærulea.
Periploca græca.
Polygonum baldschuanicum.
Pueraria hirsuta.
Solanum jasminoides var. grandiflorum.
Trachelospermum jasminoides.
Vitis æstivalis.
Vitis cordifolia.
Vitis Labrusca.
Vitis rotundifolia.
Wisteria chinensis.
Wisteria chinensis var. alba.
Wisteria chinensis flore-pleno.
Wisteria multi-juga.
Wisteria speciosa.

Cotoneaster rotundifolia var. lanata.
Cotoneaster Simonsii.
Cotoneaster thymifolia.
Daphne Cneorum.
Elæagnus macrophylla.
Elæagnus pungens.
Elæagnus pungens var. Simoni.
Elæagnus variegata.
Eriobotrya japonica.
Escallonia montevidensis.
Escallonia virgata.
Evonymus japonica.
Evonymus japonica var. aureo-variegata.
Evonymus japonica var. microphylla.
Fuchsia corallina.
Fuchsia gracilis.
Gardenia jasminoides.
Gardenia jasminoides var. Fortuniana.
Gardenia jasminoides var. radi-cans.
Gardenia jasminoides var. Veitchii.
Ilex Aquifolium.
Ilex Aquifolium var. aureo-regina.
Ilex Aquifolium var. ferox.
Ilex crenata.
Ilex glabra.
Ilex integra.
Ilex latifolia.
Ilex vomitoria.

Illicium anisatum.
Ixora chinensis.
Kalmia angustifolia.
Kalmia latifolia.
Laurus nobilis.
Leiophyllum buxifolium.
Leucothoe Catesbaei.
Leucothoe populifolia.
Ligustrum coriaceum.
Ligustrum excelsum superbum.
Ligustrum japonicum.
Ligustrum lucidum.
Ligustrum macrophyllum.
Ligustrum marginatum aureum.
Ligustrum nepalense.
Ligustrum Quihoui.
Ligustrum sinense.
Mahonia Aquifolium.
Mahonia japonica.
Mahonia repens.
Mahonia pinnata.
Michelia fuscata.
Myrtus communis.
Nandina domestica.
Nerium.
Osmanthus Aquifolium.
Osmanthus fragrans.
Osmanthus Fortunei.
Pernettya mucronata.
Pernettya speciosa.
Phillyrea angustifolia.
Phillyrea decora.

Photinia serrulata.
Pieris floribunda.
Pieris japonica.
Pittosporum Tobira.
Prunus caroliniana.
Prunus Laurocerasus var. schipkaensis.
Prunus lusitanica.
Pyracantha coccinea.
Pyracantha coccinea var. Landii.
Raphiolepis indica.
Rhododendron arboreum.
Rhododendron arbutifolium.
Rhododendron catawbiense.
Rhododendron catawbiense hybridum.
Rhododendron maximum.
Rhododendron myrtifolium.
Rhododendron ponticum.
Rhododendron punctatum.
Skimmia japonica.
Thea sinensis.
Veronica Traversii.
Viburnum odoratissimum.
Viburnum suspensum.
Viburnum Tinus.
Yucca filamentosa.
Yucca glauca.
Yucca gloriosa.
Yucca Trecaleana.

3058. *Berberis Thunbergii*.

2. *Coastal Zone* extends from the Fall Line, as outlined under the Piedmont Zone, to the Atlantic Ocean and Gulf of Mexico, but exclusive of that part of Florida south of a line drawn across the state to St. Augustine and Cedar Keys.

Deciduous shrubs for the Coastal Zone.

Acacia Farnesiana.
Acanthopanax pentaphyllum.
Æsculus octandra.
Æsculus Pavia.
Amelanchier rotundifolia.
Amorpha canescens.
Amorpha fruticosa.
Aronia arbutifolia.
Azalea arborescens.
Azalea lutea.
Azalea nudiflora.
Azalea viscosa.
Berberis aristata.
Berberis sinensis.
Berberis Thunbergii.
Berberis vulgaris.
Berberis vulgaris var. atropurpurea.
Buddleia Davidii.
Buddleia Davidii var. magnifica.
Buddleia intermedia.
Buddleia japonica.
Buddleia Lindleyana.
Buddleia officinalis.
Casalpinia Pilleisii.
Callicarpa americana.
Callicarpa purpurea.
Calycanthus fertilis.
Calycanthus florida.
Calycanthus occidentalis.
Caryopteris incana.
Cassia macrantha.
Ceanothus americanus.
Ceanothus hybridus.
Cephalanthus occidentalis.
Cercis japonica.
Cercis Siliquastrum.
Chenomeles japonica.
Chilopsis saligna.
Clerodendron trichotomum.
Clethra alnifolia.
Cornus alba.

Cornus Amomum.
Cornus sanguinea.
Coronilla Emerus.
Corylus americana.
Cotoneaster multiflora.
Cotoneaster racemiflora.
Deutzia rosea.
Deutzia Lemoinei.
Deutzia scabra var. candidissima.
Deutzia scabra var. flore-pleno rosea.
Deutzia scabra, Pride of Rochester.
Deutzia Sieboldiana.
Diervilla florida.
Diervilla hybrida.
Dicra palustris.
Elæagnus angustifolia.
Elæagnus multiflora.
Elæagnus parvifolia.
Elæagnus umbellata.
Erythrina Crista-galli.
Evonymus alata.
Evonymus americana.
Evonymus europæa.
Evonymus nana.
Evonymus patens.
Exochorda Korolkowii.
Exochorda racemosa.
Fontanesia Fortunei.
Fontanesia phillyræoides.
Forsythia intermedia.
Forsythia suspensa.
Forsythia suspensa var. Fortunei.
Forsythia viridissima.
Hamamelis virginiana.
Hibiscus syriacus.
Hippophaë rhamnoides.
Hydrangea arborescens.

Hydrangea arborescens var. *sterilis*.
Hydrangea Hortensis.
Hydrangea quercifolia.
Hypericum calycinum.
Hypericum corymbosum.
Hypericum glomeratum.
Hypericum lobocarpum.
Hypericum Moserianum.
Hypericum prolificum.
Ilex decidua.
Ilex verticillata.
Indigofera Gerardiana.
Itea virginica.
Jasminum fruticans.
Jasminum humile.
Jasminum nudiflorum.
Jasminum officinale.
Kerria japonica.
Kerria japonica var. *argenteo-variegata*.
Kerria japonica var. *flore-pleno*.
Lagerstroemia indica.
Lespedeza bicolor.
Lespedeza Sieboldii.
Ligustrum acuminatum.
Ligustrum amurense.
Ligustrum Iboia.
Ligustrum Iboia var. *Regelianum*.
Ligustrum ovalifolium.
Ligustrum vulgare.
Lonicera bella.
Lonicera fragrantissima.
Lonicera gracilipes.
Lonicera Morrowii.
Lonicera Ruprechtiana.
Lonicera Standishii.
Lonicera tatarica.
Lycium halimifolium.
Meratia praecox.
Myrica carolinensis.
Myrica cerifera.
Myricaria germanica.
Neviusia alabamensis.
Paliurus Spina-Christi.
Philadelphus coronarius.
Philadelphus coronarius var. *flore-pleno*.
Philadelphus grandiflorus (coronarius var.).
Philadelphus inodorus.
Philadelphus pubescens.
Philadelphus laxus.
Philadelphus Lemoinei.
Philadelphus Lewisii.
Philadelphus pubescens.
Philadelphus, Avalanche.
Philadelphus, Mont Blanc.
Physocarpus opulifolius.
Poncirus trifoliata.
Potentilla fruticosa.
Prunus japonica.
Prunus maritima.
Prunus pumila.
Prunus trilobata.
Punica granatum.
Rhamnus cathartica.
Rhodotypos kerrioides.
Rhus canadensis.

Vines for the Coastal Zone.

Akebia quinata.
Akebia lobata.
Ampelopsis arborea.
Ampelopsis heterophylla var. *elegans*.
Antigonon leptopus.
Berchemia racemosa.
Bignonia capreolata.
Campsis chinensis.
Campsis hybrida.
Campsis, Mme. Gallen.
Campsis radicans.
Clematis crispa.
Clematis Flammula.
Clematis paniculata.
Clematis texensis.
Decumaria barbara.
Dioscorea Batatas.
Elaeagnus reflexa.
Evonymus radicans.
Evonymus radicans var. *variegata*.
Ficus pumila.
Gelsemium sempervirens.
Gelsemium sempervirens *flore-pleno*.
Hedera canariensis.
Hedera helix.
Jasminum primulinum.

Rhus Michauxii.
Ribes curvatum.
Robinia hispida.
Rosmarinus officinalis.
Rosa carolina.
Rosa rugosa.
Rosa setigera.
Roses, Bourbon.
Roses, Bourbons.
Roses, Brier and Penzance.
Sweetbriars.
Roses, Hybrid Perpetual.
Roses, Hybrid Tea.
Roses, Japanese.
Roses, Monthly or China.
Roses, Polyantha.
Roses, Tea.
Rubus laciniatus.
Salix incana.
Salix sericea.
Salvia Greggii.
Salvia Greggii var. *alba*.
Sambucus canadensis.
Sambucus nigra.
Sambucus nigra var. *laciniata*.
Spartium junceum.
Spiraea albiflora.
Spiraea arguta.
Spiraea Billardii.
Spiraea blanda.
Spiraea Bumalda.
Spiraea cantonensis.
Spiraea cantonensis *flore-pleno*.
Spiraea Douglasii.
Spiraea Fontenaysii.
Spiraea Fortunei var. *semperflorens*.
Spiraea Froebeli.
Spiraea japonica.
Spiraea macrophylla.
Spiraea prunifolia.
Spiraea prunifolia *flore-pleno*.
Spiraea revirens.
Spiraea Thunbergii.
Spiraea Van Houttei.
Stephanandra incisa.
Stewartia pentagyna.
Styrax americana.
Styrax japonica.
Symphoricarpos microphyllus.
Symphoricarpos orbiculatus.
Syringa chinensis.
Syringa pectinatifolia.
Syringa pectinatifolia.
Tamarix gallica.
Tamarix gallica var. *indica*.
Tamarix juniperina.
Tamarix hispida var. *aestivalis*.
Tamarix oedocarpa.
Tamarix parviflora.
Viburnum macrocephalum.
Viburnum nudum.
Viburnum Opulus var. *sterile*.
Vitex Agnus-castus.
Vitex incisa.
Zenobia speciosa.

Kadsura japonica.
Lonicera americana.
Lonicera chinensis.
Lonicera flava.
Lonicera glaucescens.
Lonicera Heckrottii.
Lonicera japonica.
Lonicera japonica var. *aureo-reticulata*.
Lonicera Periclymenum var. *belgica*.
Lonicera prolifera.
Lonicera sempervirens.
Lonicera Vilmorinii.
Parthenocissus Henryana.
Parthenocissus quinquefolia.
Parthenocissus quinquefolia var. *Engelmannii*.
Parthenocissus tricuspidata var. *Veitchii*.
Passiflora caerulea.
Periploca graeca.
Polygonum baldschuanicum.
Pueraria hirsuta.
Pyrostegia venusta.
Solanum jasminoides var. *grandiflorum*.
Trachelospermum jasminoides.
Vitis aestivalis.

Vitis cordifolia.
Vitis rotundifolia.
Wisteria chinensis.
Wisteria chinensis var. *alba*.

Wisteria chinensis var. *flore-pleno*.
Wisteria multijuga.
Wisteria speciosa.

Broad-leaved evergreens for the Coastal Zone.

Abelia floribunda.
Abelia grandiflora.
Arbutus Unedo.
Ardisia crenulata var. *rubra*.
Azalea amona.
Azalea indica.
Azalea obtusa.

Ilex integra.
Ilex latifolia.
Ilex vomitoria.
Illicium anisatum.
Ixora chinensis.
Kalmia latifolia.
Laurus nobilis.

3059. A Cherokee rose cover, in the South.

Berberis buxifolia.
Berberis Darwinii.
Berberis ilicifolia.
Berberis Neubertii.
Berberis stenophylla.
Buxus japonica var. *aurea*.
Buxus sempervirens.
Buxus sempervirens var. *Handworthii*.
Buxus sempervirens var. *suffruticosa*.
Callistemon lanceolatus.
Camellia japonica.
Cleyera ochnacea.
Cotoneaster horizontalis.
Cotoneaster microphylla.
Cotoneaster microphylla var. *glacialis*.
Cotoneaster rotundifolia.
Cotoneaster rotundifolia var. *lanata*.
Cotoneaster Simonsii.
Cotoneaster thymifolia.
Elaeagnus macrophylla.
Elaeagnus pungens.
Elaeagnus pungens var. *Simoni*.
Elaeagnus variegata.
Eriobotrya japonica.
Escallonia virgata.
Escallonia montevidensis.
Evonymus japonica.
Evonymus japonica var. *aureo-variegata*.
Evonymus japonica var. *microphylla*.
Fuchsia corallina.
Fuchsia gracilis.
Gardenia jasminoides.
Gardenia jasminoides var. *Fortuniana*.
Gardenia jasminoides var. *radicans*.
Gardenia jasminoides var. *Veitchii*.
Ilex cornuta.
Ilex crenata.
Ilex glabra.

Leiophyllum buxifolium.
Leucothoe Catesbaei.
Leucothoe populifolia.
Leucothoe racemosa.
Ligustrum excelsum superbum.
Ligustrum japonicum.
Ligustrum lucidum.
Ligustrum macrophyllum.
Ligustrum marginatum *aureum*.
Ligustrum nepalense.
Ligustrum Quihoui.
Ligustrum sinense.
Mahonia Aquifolium.
Mahonia japonica.
Michelia fuscata.
Myrtus communis.
Nandina domestica.
Nerium.
Osmanthus Aquifolium.
Osmanthus Fortunei.
Osmanthus fragrans.
Pernettya mucronata.
Pernettya speciosa.
Phillyrea angustifolia.
Phillyrea decora.
Photinia serrulata.
Pieris floribunda.
Pieris japonica.
Pittosporum Tobira.
Prunus caroliniana.
Prunus Laurocerasus.
Prunus Laurocerasus var. *schipkaensis*.
Prunus lusitanica.
Pyraecantha coccinea.
Pyraecantha coccinea var. *Lalandii*.
Raphiolepis indica.
Thea sinensis.
Viburnum odoratissimum.
Viburnum suspensum.
Viburnum Tinus.
Yucca aloifolia.
Yucca filamentosa.
Yucca gloriosa.
Yucca Treculeana.

3. *Mountain or Upper Zone* includes all that territory above Harper's Ferry, Maryland; Roanoke, Virginia; Winston-Salem, Morganton, and Rutherfordton, North Carolina; Spartanburg and Pendleton, South Carolina;

Gainesville and Cartersville, Georgia; Huntsville, Alabama; Murfreesboro, Tennessee, and thence north to the Kentucky line.

Deciduous shrubs for the Mountain or Upper Zone

Acanthopanax pentaphyllum.
Acer japonica.
Æsculus octandra.
Æsculus Pavia.
Amelanchier atropurpurea.
Amelanchier canadensis.
Amelanchier rotundifolia.
Amorpha canescens.
Amorpha fruticosa.
Amorpha glabra.
Amorpha tennesseensis.
Aralia chinensis var. *mandschurica.*
Aronia arbutifolia.
Aronia melanocarpa.
Ascyrum hypericoides.
Baccharis halimifolia.
Benzoin æstivale.
Berberis asiatica.
Berberis canadensis.
Berberis heteropoda.
Berberis Sieboldii.
Berberis sinensis.
Berberis Thunbergii.
Berberis vulgaris.
Berberis vulgaris var. *atropurpurea.*
Buckleya distichophylla.
Buddleia Davidii var. *magnifica.*
Buddleia intermedia.
Buddleia japonica.
Buddleia Lindleyana.
Callicarpa americana.
Callicarpa purpurea.
Calycanthus fertilis.
Calycanthus florida.
Calycanthus occidentalis.
Caragana arborescens.
Caragana Chamagui.
Ceanothus americanus.
Ceanothus Fendleri.
Ceanothus hybridus.
Cephalanthus occidentalis.
Cercis chinensis.
Cercis Siliquastrum.
Chenomeles japonica.
Chilopsis saligna.
Clerodendron trichotomum.
Clethra alnifolia.
Colutea arborescens.
Comptonia asplenifolia.
Cornus alba.
Cornus alba var. *Spathii.*
Cornus Amomum.
Cornus mas.
Cornus racemosa.
Cornus rugosa.
Cornus sanguinea.
Cornus stolonifera.
Cornus stolonifera var. *flaviramea.*
Coronilla Emerus.
Corylopsis pauciflora.
Corylus americana.
Corylus Avellana.
Corylus Avellana var. *laciniata.*
Corylus maxima var. *purpurea.*
Corylus rostrata.
Cotoneaster acutifolia.
Cotoneaster multiflora.
Cotoneaster racemiflora.
Cratægus coccinea.
Cratægus Oxyacantha.
Cratægus Phæocyprium.
Cytisus præcox.
Cytisus scoparius.
Daphne Mezereum vars. *alba* and *rubra.*
Daphne Genkwa.
Deutzia gracilis.
Deutzia Lemoinei.
Deutzia rosea.
Deutzia scabra.
Deutzia scabra var. *candidissima.*
Deutzia scabra var. *plena.*
Deutzia scabra, *Pride of Rochester.*
Deutzia Sieboldiana.
Diervilla florida.
Diervilla hybrida.
Diervilla rivularis.
Diervilla sessilifolia.
Dirca palustris.

Elæagnus angustifolia.
Elæagnus argentea.
Elæagnus multiflora.
Elæagnus parvifolia.
Elæagnus umbellata.
Evonymus alata.
Evonymus americana.
Evonymus Bungeana.
Evonymus europæa.
Evonymus Maackii.
Evonymus nana.
Evonymus patens.
Exochorda Korolkowii.
Exochorda racemosa.
Fontanesia Fortunei.
Fontanesia phyllæroides.
Forestiera acuminata.
Forestiera ligustrina.
Forsythia intermedia.
Forsythia suspensa.
Forsythia suspensa var. *Fortunei.*
Forsythia viridissima.
Fothergilla Gardenii.
Fothergilla major.
Fothergilla parviflora.
Genista germanica.
Genista tinctoria.
Halimodendron halodendron.
Hamamelis virginiana.
Hibiscus syriacus.
Hippophaë rhamnoides.
Holodiscus discolor.
Hydrangea arborescens.
Hydrangea arborescens var. *sterilis.*
Hydrangea Hortensia.
Hydrangea paniculata.
Hydrangea paniculata var. *grandiflora.*
Hydrangea paniculata var. *præcox.*
Hydrangea quercifolia.
Hydrangea radiata.
Hypericum aureum.
Hypericum calycinum.
Hypericum densiflorum.
Hypericum glomeratum.
Hypericum lobocarpum.
Hypericum Moserianum.
Hypericum nudiflorum.
Hypericum prolificum.
Ilex decidua.
Ilex verticillata.
Indigofera Gerardiana.
Itea virginica.
Jasminum fruticans.
Jasminum humile.
Jasminum nudiflorum.
Jasminum officinale.
Kerria japonica.
Kerria japonica var. *argenteo-variegata.*
Kerria japonica flore-pleno.
Lagerstræmia indica.
Lepedeza bicolor.
Lepedeza Sieboldii.
Leucothoë racemosa.
Leucothoë recurva.
Ligustrum acuminatum.
Ligustrum amurense.
Ligustrum Ibo.
Ligustrum Ibo var. *Regelianum.*
Ligustrum ovalifolium.
Ligustrum vulgare.
Lonicera bella.
Lonicera fragrantissima.
Lonicera gracilipes.
Lonicera Morrowii.
Lonicera muscaviensis.
Lonicera pyrenaica.
Lonicera Pyrethiana.
Lonicera spinosa.
Lonicera Standishii.
Lonicera tatarica.
Lonicera thibetica.
Lonicera Xylosteum.
Lycium vulgare.
Lyonia ligustrina.
Menziesia pilosa.
Meratia præcox.
Muehlenbeckia complexa.
Myrica carolinensis.

Myrica cerifera.
Myrica Gale.
Myricaria germanica.
Neviusia alabamensis.
Paliurus Spina-Christi.
Philadelphus coronarius.
Philadelphus coronarius var. *flore-pleno.*
Philadelphus Falconeri.
Philadelphus floridus.
Philadelphus gloriosus.
Philadelphus grandiflorus (coronarius var.).
Philadelphus alata.
Philadelphus hirsutus.
Philadelphus inodorus.
Philadelphus laxus.
Philadelphus Lemoinei.
Philadelphus Lewisii.
Philadelphus pubescens.
Philadelphus Avalanche.
Philadelphus, Mont Blanc.
Photinia villosa.
Physocarpus opulifolius.
Physocarpus opulifolius var. *aureus.*
Pieris mariana.
Poncirus trifoliata.
Potentilla fruticosa.
Prunus Besseyi.
Prunus incana.
Prunus japonica.
Prunus maritima.
Prunus pumila.
Prunus triloba.
Punica Granatum.
Rhamnus cathartica.
Rhamnus Frangula.
Rhododendron arborescens.
Rhododendron canadense.
Rhododendron gandavensis.
Rhododendron arborescens.
Rhododendron luteum.
Rhododendron nudiflorum.
Rhododendron ponticum.
Rhododendron Vaseyi.
Rhododendron viscosum.
Rhodotypos kerrioides.
Rhus canadensis.
Rhus Michauxii.
Ribes aureum.
Ribes curvatum.
Ribes Cynosbatii.
Ribes glandulosum.
Ribes Gordonianum.
Ribes nigrum.
Ribes rotundifolium.
Ribes sanguineum.
Robinia hispida.
Rosa alpina.
Rosa blanda.
Rosa carolina.
Rosa rubiginosa.
Rosa rugosa.
Rosa setigera.
Roses, Bourbon.
Roses, Brier and Penzance Sweetbriers
Roses, Hybrid Perpetual.
Roses, Hybrid Tea.
Roses, Japanese.
Roses, Monthly or China.
Roses, Moss.
Roses, Polyantha.
Roses, Tea.
Rosmarinus officinalis.
Rubus laciniatus.
Rubus odoratus.
Rubus parviflorus.
Rubus roseiflorus.
Salix discolor.
Salix humilis.
Salix incana.
Salix lucida.
Salix sericea.
Salix tristis.
Sambucus canadensis.
Sambucus nigra.
Sambucus nigra var. *laciniata.*
Sambucus pubens.
Shepherdia argentea.
Spartium junceum.
Spiræa alba.

Spiræa albiflora.
Spiræa arguta.
Spiræa bethehemensis var. *rubra.*
Spiræa Billardii.
Spiræa Billardii var. *longipedunculata.*
Spiræa blanda.
Spiræa Bumalda.
Spiræa californica.
Spiræa cantonensis.
Spiræa cantonensis flore-pleno.
Spiræa crenata.
Spiræa Douglasii.
Spiræa eximia.
Spiræa Fontenaysii.
Spiræa Fortunei var. *semperflorens.*
Spiræa Froebelii.
Spiræa japonica.
Spiræa Lenneana.
Spiræa macrophylla.
Spiræa Margaritæ.
Spiræa Menziesii.
Spiræa nipponica.
Spiræa prunifolia.
Spiræa prunifolia flore-pleno.
Spiræa Schinabeckii.
Spiræa Thunbergii.
Spiræa trilobata.
Spiræa Van Houttei.
Spiræa revirescens.
Spiræa syringæflora.
Spiræa tomentosa.
Spiræa virginiana.
Staphylea Bumalda.
Staphylea colchica.
Staphylea pinnata.
Staphylea trifolia.
Stephanandra incisæ.
Stephanandra Tanakæ.
Stewartia pentagyna.
Stewartia Pseudo-Camellia.
Styrax americana.
Styrax japonica.
Styrax Obassia.
Symphoricarpos albus.
Symphoricarpos microphyllus.
Symphoricarpos occidentalis.
Symphoricarpos orbiculatus.
Symphoricarpos ovatus.
Syringa chinensis.
Syringa Josikea.
Syringa pekinensis.
Syringa persica.
Syringa villosa.
Syringa vulgaris.
Syringa vulgaris, named *sorta.*
Tamarix gallica.
Tamarix gallica var. *indica.*
Tamarix hispida var. *æstivale.*
Tamarix juniperina.
Tamarix Odessana.
Tamarix parviflora.
Ulex europæus.
Ulex nanus.
Vaccinium corymbosum.
Vaccinium pallidum.
Vaccinium pennsylvanicum.
Viburnum acerifolium.
Viburnum alnifolium.
Viburnum cassinoides.
Viburnum dentatum.
Viburnum dilatatum.
Viburnum Lantana.
Viburnum macrocephalum.
Viburnum macrocephalum var. *sterile.*
Viburnum nudum.
Viburnum Opulus.
Viburnum Opulus var. *nanum.*
Viburnum Opulus var. *sterile.*
Viburnum Sieboldii.
Viburnum tomentosum.
Viburnum tomentosum var. *plenum.*
Vitex Agnus-castus.
Vitex incisæ.
Xanthorrhiza apiifolia.
Zenobia speciosa.

Vines for the Mountain Zone.

Actinidia arguta.
Actinidia Kolomitka.
Akebia lobata.
Akebia quinata.
Ampelopsis arborea.
Ampelopsis cordata.

Ampelopsis heterophylla.
Ampelopsis heterophylla var. *elegans.*
Aristolochia macrophylla.
Berchemia racemosa.
Bignonia capreolata.

Brunnicheria cirrhosa (a somewhat shrubby, tendril-climbing plant native in eastern United States; allied to *Polygonella*).
Campsis chinensis.
Campsis hybrida.
Campsis, *Mme. Gallen*.
Campsis radicans.
Celastrus orbiculatus.
Celastrus scandens.
Clematis apifolia.
Clematis crispa.
Clematis flammula.
Clematis hybrida.
Clematis montana.
Clematis orientalis.
Clematis paniculata.
Clematis Vioria.
Clematis virginiana.
Clematis Vitalba.
Decumaria barbara.
Elaeagnus reflexa.
Evonymus radicans.
Evonymus radicans var. *variegata*.
Evonymus radicans var. *vegeta*.
Gelsemium sempervirens.
Hedera helix.
Humulus Lupulus.
Hydrangea petiolaris.
Lonicera americana.

Lonicera chinensis.
Lonicera etrusca.
Lonicera flava.
Lonicera glaucescens.
Lonicera Heckrottii.
Lonicera japonica.
Lonicera japonica var. *aureo-reticulata*.
Lonicera Periclymenum var. *belgica*.
Lonicera prolifera.
Lonicera sempervirens.
Lonicera Vilmorinii.
Menispermum canadense.
Parthenocissus quinquefolia.
Parthenocissus quinquefolia var. *Engelmannii*.
Parthenocissus tricuspidata var. *Veitchii*.
Periploca græca.
Polygonum clinode.
Pueraria hirsuta.
Vitis aestivalis.
Vitis cordifolia.
Vitis Labrusca.
Vitis rotundifolia.
Wisteria chinensis.
Wisteria chinensis var. *alba*.
Wisteria chinensis flore-pleno.
Wisteria multijuga.
Wisteria speciosa.

under various subheads those shrubs which are undoubtedly suited for the purpose indicated and which have proved themselves well adapted to the various sections of the state.

Many of the deciduous ornamental plants commonly employed in the eastern United States for landscape planting have purposely been omitted, as they fail to produce the same wonderful spring-flower effects under the different climatic conditions of California. Only such deciduous shrubs as bloom freely and seem to have become more or less adapted to the drier climate of this state are included.

Because of the great variety of climatic and soil conditions throughout the state, it has become necessary to think of it as divided into three general regions,—the interior valleys, the San Francisco Bay district, and that part of southern California in the vicinity of the coast.

Those kinds marked with a dagger (†) will thrive only in southern California; those with a star (*) will grow in the South and as far north on the coast as the San Francisco Bay region, while such kinds as have no abbreviation attached will probably grow in all the cultivated areas of the state, including the large interior valleys. With one exception, the shrubs in the lists are arranged in the order of their desirability for the purposes described by the subhead. By cross-reference, the lists should prove helpful in selecting species of certain characteristics for given climatic and cultural conditions to produce the results desired.

Group I. Shrubs which are more or less resistant to conditions created by full shade.

While the larger number of these shrubs will produce the best results in half-shade, or even in full sun if given sufficient water, they are more or less tolerant to conditions existing under live oak trees, in courts, or on the north sides of buildings.

Evergreen.

Vaccinium ovatum (3 feet).
 *Tree ferns in variety (6 to 10 feet).
Aucuba japonica (4 feet).
 **Coprosma Baueri* (6 feet).
Evonymus in variety (6 to 8 feet).
Fatsia japonica (6 feet).
Mahonia in variety (4 feet).
Sollya heterophylla (3 feet).
 †*Asystasia bella* (3 feet).
Hypericum calycinum (1 foot).
Ligustrum in variety (6 to 10 feet).
Osmanthus in variety (3 to 10 feet).
Buxus sempervirens (2 to 8 feet).
 **Abutilon striatum* (8 feet).
Abelia grandiflora (6 feet).
Azalea indica (4 feet).
Hydrangea Hortensia (5 feet).
Nandina domestica (6 feet).
Berberis Darwinii (5 feet).
 **Trachelospermum jasminoides* (3 feet).
Jasminum humile (6 feet).
 **Fuchsia* in variety (6 feet).
Myrtus communis (3 to 5 feet).
 **Myrtus Ugni* (4 feet).
Eugenia apiculata (8 feet).
 **Philadelphus mexicanus* (5 feet).
Cotoneaster horizontalis (2 to 3 feet).
 **Reinwardtia trigyna* (3 feet).

Deciduous.

Symphoricarpos racemosus (3 feet).
Ribes speciosum (3 feet).
Azalea sinense (3 feet).
Kerria japonica (6 feet).
Chænomelos japonica (6 feet).

Group II. Shrubs which thrive most successfully in half-shade in California.

Many plants will produce the best results in full sun if favorable moisture conditions can be maintained throughout the summer, but the amount of sun exposure that plants in this list will withstand depends largely

Broad-leaved evergreens for the Mountain Zone.

Abelia grandiflora.
Andromeda polifolia.
Arctostaphylos Uva-ursi.
Azalea amœna.
Azalea indica (hardy sorts).
Azalea indica Kaempferi (Sargent's hybrids).
Azalea obtusa.
Berberis hakeoides.
Berberis ilicifolia.
Berberis Neubertii.
Berberis Sargentiana.
Buxus japonica var. *aurea*.
Buxus sempervirens.
Buxus sempervirens var. *Handworthii*.
Buxus sempervirens var. *suffruticosa*.
Calluna vulgaris.
Calluna vulgaris var. *alba*.
Chamædaphne calyculata.
Cotoneaster horizontalis.
Cotoneaster microphylla.
Cotoneaster microphylla var. *glacialis*.
Cotoneaster rotundifolia.
Cotoneaster rotundifolia var. *lanata*.
Cotoneaster Simonsii.
Cotoneaster thymifolia.
Daphne Blagayana.
Daphne Cneorum.
Elaeagnus macrophylla.
Elaeagnus variegata.
Ephedra distachya.
Erica carnea.
Erica stricta.
Erica Tetralix.
Erica vagans.
Evonymus japonica.
Evonymus japonica var. *aureo-variegata*.
Evonymus japonica var. *microphylla*.
Evonymus patens.
Ilex Aquifolium.
Ilex Aquifolium var. *aureo-regina*.
Ilex Aquifolium var. *ferox*.
Ilex Aquifolium var. *ferox variegata*.
Ilex Aquifolium var. *laurifolia*.
Ilex cornuta.
Ilex crenata.
Ilex glabra.
Ilex vomitoria.
Kalmia angustifolia.
Kalmia glauca.
Kalmia latifolia.
Leiophyllum buxifolium.
Leiophyllum buxifolium var. *prostratum*.
Leucothoe Catesbaei.
Leucothoe populifolia.
Ligustrum coriaceum.
Ligustrum japonicum.
Ligustrum lucidum.
Ligustrum macrophyllum.
Ligustrum nepalense.
Ligustrum Quiboui.
Ligustrum sinense.
Mahonia Aquifolium.
Mahonia japonica.
Mahonia pinnata.
Mahonia repens.
Nandina domestica.
Osmanthus Aquifolium.
Osmanthus Fortunei.
Phillyrea angustifolia.
Phillyrea decora.
Photinia serrulata.
Pieris floribunda.
Pieris japonica.
Prunus Laurocerasus.
Prunus Laurocerasus var. *schipkaensis*.
Prunus lusitanica.
Pyracantha coccinea.
Pyracantha coccinea var. *Lalandii*.
Rhododendron arboreum.
Rhododendron arbutifolium.
Rhododendron catawbiense.
Rhododendron catawbiense var. *hybridum*.
Rhododendron maximum.
Rhododendron myrtifolium.
Rhododendron punctatum.
Rhododendron ponticum.
Rhododendron Wilsonii.
Skimmia japonica.
Veronica Traversii.
Yucca filamentosa.
Yucca glauca.
Yucca gloriosa.
Yucca Trecaleana.

L. A. BERCKMANS.

Ornamental shrubs for California.

No pretensions have been made in compiling the following list to include every plant of desirable ornamental characteristics that will grow in California. Many exotics are being continually introduced, some of which have proved highly satisfactory, while others are little known. The effort has been rather to classify

on the section of the state in which they are located and on the amount of water they receive. Because of neglect aided by the long dry season, they often do better, however, in half-shade where the soil does not dry out so rapidly.

Evergreen.

- Daphne odora (3 feet).
- Erica in variety (2 to 5 feet).
- *Coprosma Baueri (6 feet).
- *Philadelphus mexicanus (5 feet).
- Abelia grandiflora (6 feet).
- Sollya heterophylla (3 feet).
- *Fuchsia in variety (6 feet).
- Azara microphylla (8 feet).
- Hydrangea Hortensia (5 feet).
- Cotoneaster horizontalis (2 to 3 feet).
- Camellia in variety (8 feet).
- Hypericum calycinum (1 foot).
- Hypericum Moserianum (3 feet).
- Mahonia in variety (4 feet).
- Fatsia japonica (6 feet).
- *Abutilon striatum (8 feet).
- *Trachelospermum jasminoides (3 feet).
- Aucuba japonica (4 feet).
- Nandina domestica (6 feet).
- Escallonia rubra (6 feet).
- Pittosporum Tobira (12 feet).
- Pittosporum heterophyllum (3 feet).
- †Cuphea in variety (2 feet).
- †Clerodendron in variety (6 feet).
- Buxus in variety (2 to 8 feet).
- *Cestrum in variety (8 feet).
- Cornus capitata (10 feet).
- Azalea in variety (4 feet).
- Rhododendron in variety (5 feet).
- Osmanthus in variety (3 to 10 feet).
- Michelia fuscata (6 feet).
- Pyracantha crenulata (6 feet).
- Viburnum Tinus var. lucidum (10 feet).
- Garrya elliptica (8 feet).
- Arbutus Menziesii (25 feet).
- *Myrtus Ugni (4 feet).
- Ilex Aquifolium (6 to 10 feet).
- Maytenus Boaria (10 to 20 feet).
- *Heliotropium in variety (4 feet).
- *Plumbago capensis (4 feet).
- *Statice in variety (2 feet).
- Chorizema ilicifolium (5 feet).
- Ternstroemia japonica (8 feet).
- †Asystasia bella (3 feet).
- *Tibouchina splendens (5 feet).
- *Jacobinia in variety (3 feet).
- †Strobilanthes Dyerianus (5 feet).
- †Templetonia retusa (3 feet).
- †Thevetia nereifolia (8 feet).
- *Melianthus major (4 feet).
- *Tree ferns in variety (6 to 10 feet).
- Prunus Laurocerasus (8 to 10 feet).

Deciduous.

- Chaenomeles japonica (6 feet).
- Diervilla in variety (8 feet).
- Kerria japonica (6 feet).
- Deutzia in variety (4 feet).
- Berberis Thunbergii (3 feet).
- Pæonia suffruticosa (3 feet).
- Rhododendron, Hinodigiri (3 feet).
- Rhododendron sinense (3 feet).
- Ribes in variety (6 to 8 feet).
- Philadelphus in variety (6 feet).
- Spiraea Van Houttei (4 feet).
- Spiraea cantoniensis (5 feet).
- Viburnum Opulus var. sterile (8 feet).
- Viburnum tomentosum var. plicatum (6 feet).
- Syringa in variety (6 to 10 feet).
- Magnolia in variety (6 to 10 feet).

Group III. Shrubs which thrive most successfully in protected sunny locations.

Many plants, native of countries warmer than California, require warm moist situations.

Evergreen.

- Acacia in variety (5 to 20 feet).
- †Acocanthera spectabilis (6 feet).
- †Bauhinia in variety (8 to 10 feet).
- Berberis Darwinii (6 to 8 feet).
- †Bouvardia Humboldtii (5 feet).
- *Buddleia Davidii var. Veitchiana (6 to 8 feet).
- *Cantua buxifolia (8 feet).
- *Carissa grandiflora (4 feet).
- *Cassia in variety (4 to 10 feet).
- Choisya ternata (6 feet).

3060. A bower or arbor of rustic work, with roses and clematis.—To show an English scene (Garden of S. Charrington, from "Gardening Illustrated").

- Cistus in variety (2 to 4 feet).
- Cotoneaster in variety (2 to 8 feet).
- Cytisus in variety (6 to 8 feet).
- *Diosma ericoides (4 feet).
- †Dombeya natalensis (10 to 12 feet).
- †Dombeya spectabilis (8 to 10 feet).
- *Duranta Plumieri (6 to 8 feet).
- Escallonia montevidensis (8 feet).
- Escallonia pulverulenta (8 to 10 feet).
- Escallonia rosea (8 feet).
- Eugenia apiculata (8 feet).
- †Eugenia jambolana (10 to 15 feet).
- *Eugenia myrtifolia (10 to 15 feet).
- †Eugenia uniflora (6 to 8 feet).
- †Euphorbia pulcherrima (6 to 8 feet).
- Feijoa Sellowiana (8 feet).
- *Genista monosperma (6 to 8 feet).
- *Grevillea Thelemanniana (4 feet).
- *Hardenbergia monophylla (5 feet).
- †Hibiscus heterophyllus (8 feet).
- †Hibiscus Rosa-sinensis (8 to 10 feet).
- †Iochroma in variety (8 to 10 feet).
- Jasminum humile (6 feet).
- *Lantana in variety (4 to 6 feet).
- Leptospermum scoparium var. Chapmannii (8 feet).
- Leptospermum scoparium var. Nicholii (4 to 6 feet).
- Leptospermum scoparium var. bullatum (4 feet).
- Leptospermum laevigatum (6 to 10 feet).
- Lonicera nitida (4 to 6 feet).
- *Malvaviscus mollis (6 feet).
- Melaleuca in variety (6 to 10 feet).
- Metrosideros lucida (6 feet).
- Metrosideros robusta (8 feet).
- Myrtus communis (3 to 5 feet).
- Nerium Oleander (8 to 10 feet).
- †Oxera pulchella (2 to 4 feet).
- Photinia serrulata (10 to 12 feet).
- Pimelea ferruginea (4 to 6 feet).
- Pittosporum eugenoides (10 to 15 feet).
- *Pittosporum rhombifolium (10 to 15 feet).
- Pittosporum tenuifolium (10 to 15 feet).

- **Pittosporum undulatum* (10 to 15 feet).
- **Pittosporum viridiflorum* (8 to 10 feet).
- Polygala Dalmaisiana* (3 to 5 feet).
- Prunus lusitanica* (8 feet).
- **Psidium Cattleianum* (3 to 6 feet).
- Pyracantha angustifolia* (6 feet).
- Pyracantha coccinea* (6 to 8 feet).
- Quillaja Saponaria* (10 to 15 feet).
- **Raphiolepis indica* (6 to 8 feet).
- Raphiolepis umbellata* (4 to 6 feet).
- **Rhodorhiza florida* (6 feet).
- †*Salvia Sessei* (6 feet).
- **Sparmannia africana* (8 feet).
- Spartium junceum* (6 to 8 feet).
- †*Sphaeralcea umbellata* (8 feet).
- **Solanum Rantonnetii* (6 feet).
- **Streptosolen Jamesonii* (3 to 6 feet).
- **Tecoma capensis* (8 feet).
- †*Tecoma Smithii* (6 to 8 feet).
- †*Tithonia diversifolia* (8 to 10 feet).
- Veronica* in variety (2 to 6 feet).
- Viburnum suspensum* (6 feet).
- **Wigandia caracasana* (8 to 10 feet).

Group IV. Shrubs resistant to soil and climatic conditions along the California seacoast.

The plants in this list are fairly resistant to the effects of strong prevailing winds and thrive in dry sandy soils containing more or less salt and are therefore valuable for windbreaks and shelter plantings. In general, the finer the foliage and the more willowy or wire-like the branches, the more easily do they withstand the trying conditions. A noticeable exception is some few kinds of hardy palms which thrive under such conditions because of the stiff character of their leaves and stems.

Evergreen.

- Cupressus macrocarpa* (10 to 20 feet).
- Tamarix* in variety (8 feet).
- Myrica californica* (8 to 10 feet).
- Acacia longifolia* (6 to 10 feet).
- **Atriplex Breweri* (6 feet).
- Casuarina* in variety (10 to 25 feet).
- **Coprosma Baueri* (6 feet).
- Rhus integrifolia* (6 feet).
- Leptospermum* in variety (6 to 10 feet).
- Melaleuca* in variety (6 to 10 feet).
- Callistemon* in variety (4 to 8 feet).
- Myoporum laetum* (3 to 12 feet).
- Veronica* in variety (2 to 6 feet).
- **Anthyllis Barba-Jovis* (4 to 6 feet).
- Juniperus* in variety (2 to 8 feet).
- Ulex europaeus* (6 feet).
- Rhamnus californica* (8 to 10 feet).
- Ceanothus thyrsiflorus* (6 to 10 feet).
- Acacia melanoxylon* (10 to 25 feet).
- Acacia Farnesiana* (10 to 12 feet).
- Acacia armata* (6 to 8 feet).
- Coronilla glauca* (4 to 6 feet).
- Pittosporum crassifolium* (10 to 15 feet).
- Pittosporum phylliraeoides* (10 to 15 feet).
- Pittosporum Tobira* (8 to 10 feet).
- Escallonia rubra* (6 feet).
- Dodonaea* in variety (8 feet).
- Spartium junceum* (6 to 8 feet).
- Lythamnus floribundus* var. *asplenifolius* (15 to 20 feet).
- Medicago arborea* (6 feet).
- Cytisus* in variety (6 to 8 feet).
- Metrosideros tomentosa* (6 to 12 feet).
- Phillyrea latifolia* (10 feet).
- Polygala Dalmaisiana* (3 to 5 feet).
- Maytenus Boaria* (10 to 20 feet).
- Hakea* in variety (8 to 10 feet).
- Lycium chinense* (6 feet).
- Ceratonia Siliqua* (8 to 12 feet).
- Elaeagnus pungens* (6 feet).
- Artemisia arborescens* (6 feet).
- **Statice* in variety (1 foot).
- **Ficus macrophylla* (10 to 20 feet).
- **Echium* in variety (4 to 6 feet).

Palms.

- Chamaerops humilis* (6 feet).
- Phoenix canariensis* (15 feet).
- Phoenix dactylifera* (20 feet).
- Trachycarpus excelsus* (20 feet).
- Sabal Palmetto* (12 feet).
- Erythea armata* (15 feet).
- Washingtonia filifera* (20 feet).
- Erythea edulis* (15 feet).

Group V. Shrubs resistant to heat, drought, and neglect.

In some semi-arid sections of California, it is necessary to use plants that will grow more or less success-

fully under conditions of severe heat, drought, and neglect. Plants in this list are especially useful in those situations where no attention can be given after the plant is once established.

Evergreen.

- Casuarina* in variety (10 to 25 feet).
- Acacia* in variety (5 to 20 feet).
- **Atriplex Breweri* (6 feet).
- Pittosporum phylliraeoides* (10 to 15 feet).
- Olea europaea* (10 to 15 feet).
- Pittosporum crassifolium* (10 to 15 feet).
- Tristania conferta* (10 to 20 feet).
- Photinia arbutifolia* (8 to 10 feet).
- Spartium junceum* (6 to 8 feet).
- Rhamnus californica* (8 to 10 feet).
- Ceanothus* in variety (6 to 10 feet).
- Cytisus* in variety (6 to 10 feet).
- Hakea* in variety (8 to 10 feet).
- Ligustrum* in variety (8 to 10 feet).
- Callistemon* in variety (4 to 8 feet).
- Melaleucas* in variety (6 to 10 feet).
- Cistus* in variety (2 to 4 feet).
- Albizia lophantha* (10 feet).
- Parkinsonia aculeata* (8 to 10 feet).
- Nerium Oleander* (8 to 10 feet).
- Myoporum laetum* (8 to 12 feet).
- Raphiolepis umbellata* (4 to 6 feet).
- Carpenteria californica* (6 to 8 feet).
- Ceratonia Siliqua* (8 to 12 feet).
- Evonymus japonica* (6 to 8 feet).
- Arbutus Unedo* (8 feet).
- Cassia tomentosa* (8 feet).
- Cassia artemisioides* (4 feet).
- Leptospermum* in variety (6 to 10 feet).
- **Agonis flexuosa* (8 to 10 feet).
- **Calothamnus quadrifidus* (5 feet).
- Elaeagnus pungens* (6 feet).
- Romneya Coulteri* (6 feet).
- **Buddleia* in variety (6 to 8 feet).
- Coronilla glauca* (4 to 6 feet).
- Dodonaea cuneata* (6 to 8 feet).
- Dodonaea viscosa* (8 feet).
- **Echium* in variety (4 to 6 feet).
- Phillyrea latifolia* (10 feet).
- Metrosideros tomentosa* (6 to 12 feet).
- **Malvaviscus mollis* (6 feet).
- Prunus ilicifolia* var. *integrifolia* (10 to 12 feet).
- Prunus caroliniana* (10 to 12 feet).
- Pyracantha crenulata* (6 to 8 feet).

Deciduous.

- Tamarix parviflora* (6 to 8 feet).
- Tamarix hispida* var. *aestivalis* (6 to 8 feet).
- Chenomeles japonica* (6 feet).
- Punica Granatum* (6 feet).
- Berberis vulgaris* var. *atropurpurea* (6 to 8 feet).
- Evonymus europaea* (8 feet).
- Prunus cerasifera* var. *atropurpurea* (10 to 12 feet).

Group VI. Shrubs which are especially free-flowering.

Many species of ornamental shrubs are particularly free-flowering in California, while others possess several flowering periods throughout the year. Because of their tendency to bloom in the fall and winter seasons, they are especially useful in the more intensively developed gardens where all-the-year-round effects are desired.

Evergreen.

- Choisya ternata* (6 feet).
- **Cestrum elegans* (6 feet).
- Veronica* in variety (2 to 6 feet).
- Polygala Dalmaisiana* (3 to 5 feet).
- **Grevillea Thelemanniana* (4 feet).
- **Rhodorhiza florida* (6 feet).
- **Lantana* in variety (4 to 6 feet).
- **Fuchsia* in variety (6 feet).
- Sollya heterophylla* (3 feet).
- Berberis Darwinii* (6 to 8 feet).
- Escallonia rubra* (4 to 6 feet).
- **Streptosolen Jamesonii* (3 to 6 feet).
- Spartium junceum* (6 to 8 feet).
- Abelia grandiflora* (6 feet).
- †*Heterocentron roseum* (1 foot).
- **Genista monosperma* (6 to 8 feet).
- Pimelea ferruginea* (4 to 6 feet).
- †*Bouvardia Humboldtii* (5 feet).
- Cistus ladaniferus* var. *maculatus* (2 to 4 feet).
- Statice* in variety (1 foot).
- **Anthyllis Barba-Jovis* (4 to 6 feet).
- **Reinwardtia trigyna* (3 feet).
- **Lochroma* in variety (8 to 10 feet).
- Escallonia pulverulenta* (8 to 10 feet).
- **Jacobinia pauciflora* (2 feet).

- †*Dalacanthus nervosus* (2 feet).
- Cytisus racemosus* (2 to 3 feet).
- **Duranta Plumieri* (6 to 8 feet).
- Coronilla glauca* (4 to 6 feet).
- Cassia artemisioides* (4 feet).
- **Malvaviscus mollis* (6 feet).
- †*Cuphea* in variety (2 feet).
- **Philadelphus mexicanus* (5 feet).
- **Tibouchina splendens* (5 feet).
- Escallonia rosea* (8 feet).
- **Cestrum aurantiacum* (6 to 8 feet).
- Erica mediterranea* (3 feet).
- Erica melanthera* (3 feet).
- **Plumbago capensis* (4 feet).
- **Trachelospermum jasminoides* (3 feet).
- Cassia tomentosa* (8 feet).
- **Eugenia myrtifolia* (10 to 15 feet).
- †*Hibiscus* in variety (8 to 10 feet).
- **Tecoma capensis* (8 feet).
- **Swainsona galegifolia* var. *albiflora* (6 feet).
- **Calothamnus quadrifidus* (5 feet).

Group VII. Shrubs bearing ornamental fruits and berries.

The berried and fruit-bearing ornamental trees and shrubs form one of the most interesting classes of decorative plants. Not only do they produce a flower display throughout the spring and summer months but also add flashes of color for long periods in the fall and winter by their clusters of bright berries or fruits. Only those kinds bearing persistent fruit and of a color contrasting well with green foliage are acceptable in California. Such deciduous berried shrubs as have proved themselves adaptable are included in the list.

Those producing berried effects.

- Pyracantha coccinea* (6 to 8 feet).
- Pyracantha crenulata* (6 feet).
- Pyracantha angustifolia* (6 feet).
- Cotoneaster Franchetii* (4 to 6 feet).
- Cotoneaster Dielsiana* (4 to 6 feet).
- Cotoneaster horizontalis* (2 to 3 feet).
- Cotoneaster pannosa* (6 to 8 feet).
- Cotoneaster acuminata* (6 to 8 feet).
- Cotoneaster buxifolia* (2 to 3 feet).
- Cotoneaster microphylla* (2 to 3 feet).
- Cotoneaster frigida* (8 to 10 feet).
- Photinia arbutifolia* (8 to 10 feet).
- **Myrtus Ugni* (4 feet).
- **Duranta Plumieri* (6 to 8 feet).
- Berberis Darwinii* (6 to 8 feet).
- Ilex Aquifolium* (6 to 10 feet).
- **Cestrum elegans* (6 feet).
- **Cestrum aurantiacum* (6 to 8 feet).
- **Pittosporum rhombifolium* (10 to 15 feet).
- **Pittosporum viridiflorum* (10 feet).
- Arbutus Menziesii* (10 to 20 feet).
- Lycium chinense* (6 feet).
- Rhamnus californica* (8 to 10 feet).
- Rhamnus crocea* (4 feet).
- Nandina domestica* (6 feet).

Deciduous.

- Eleagnus umbellata* (10 feet).
- Symphoricarpos albus* (3 feet).
- Crataegus cordata* (10 feet).
- Berberis Thunbergii* (3 feet).
- Sorbus Aucuparia* (10 to 15 feet).
- Symphoricarpos vulgaris* (3 feet).
- Sambucus racemosa* (10 feet).

Those producing fruit effects.

- Arbutus Unedo* (8 feet).
- **Eugenia myrtifolia* (10 to 15 feet).
- †*Eugenia uniflora* (6 to 8 feet).
- Cornus capitata* (10 feet).
- **Psidium* in variety (4 to 8 feet).
- Aucuba japonica* (4 feet).
- Eriobotrya japonica* (10 to 12 feet).
- Feijoa Sellowiana* (8 feet).

Deciduous.

- Evonymus europæa* (6 to 8 feet).
- Evonymus alata* (6 to 8 feet).
- Ribes speciosum* (4 feet).
- Punica Granatum* (6 feet).
- Diospyros* in variety (6 to 8 feet).
- Rosa rugosa* (3 feet).
- Chenomeles japonica* (6 feet).
- Pyrus floribunda* (10 to 12 feet).

Group VIII. Shrubs for hedges (California).

Many shrubs of a compact habit may be used as hedge-plants. There is, however, a fairly well-estab-

lished group of desirable species that lend themselves more easily to training of this kind. Those listed below are used extensively for hedges and have been found to adapt themselves readily to the severe system of trimming and to produce the dense and compact form desired.

Low edgings or boxings (6 to 18 inches).

- Berberis Darwinii*.
- Buxus sempervirens* var. *suffruticosa*.
- **Eugenia myrtifolia*.
- Lonicera nitida*.
- Veronica buxifolia*.
- Myrtus communis* var. *microphylla*.
- Myrtus Ugni*.
- Evonymus japonica* var. *microphylla*.
- Veronica Traversii*.
- Veronica carnea*.
- Cotoneaster microphylla*.
- Erica mediterranea*.
- **Diosma ericoides*.
- **Jacobinia pauciflora*.
- Cistus ladaniferus* var. *maculatus*.

Small hedges (2 to 6 feet).

- Berberis Darwinii*.
- **Eugenia myrtifolia*.
- Eugenia apiculata*.
- Buxus sempervirens*.
- Taxus baccata*.
- Lonicera nitida*.
- Osmanthus Aquifolium* var. *myrtifolia*.
- Prunus ilicifolia*.
- Pittosporum tenuifolium*.
- Pittosporum eugenioides*.
- Myrtus communis*.
- Escallonia rubra*.
- **Atriplex Brewerii*.
- **Grevillea Thelemanniana*.
- Ligustrum sinense*.
- Ligustrum ovalifolium*.
- Choisya ternata*.
- Pyracantha crenulata*.
- **Aberia cafra*.
- Erica* in variety.
- Elæagnus pungens*.
- Pyracantha angustifolia*.
- Veronica decussata*.
- Veronica imperialis*.
- Veronica elliptica*.
- Pimelea ferruginea*.
- Viburnum Tinus* var. *strictum*.
- Leptospermum laevigatum*.
- Evonymus japonica*.
- Acacia longifolia*.
- Acacia armata*.
- Ceanothus spinosus*.
- **Psidium Cattleianum*.
- **Lantana*, dwarf hybrids.

High hedges (6 to 12 feet).

- Pittosporum tenuifolium*.
- Pittosporum eugenioides*.
- **Pittosporum undulatum*.
- Pittosporum crassifolium*.
- Prunus ilicifolia* var. *integrifolia*.
- Ligustrum ovalifolium*.
- Ligustrum japonicum*.
- Prunus caroliniana*.
- Escallonia pulverulenta*.
- Cupressus macrocarpa*.
- Hakea suaveolens*.
- Hakea saligna*.
- Acacia longifolia*.
- Acacia melanoxylon*.
- Acacia retinodes*.
- Acacia verticillata*.
- Pyracantha coccinea*.
- Spartium junceum*.

Group IX. Shrubs for ground-covers (California).

There are often banks and slopes where a lawn would be too expensive to maintain and unless covered with green foliage would remain unsightly. Other situations, especially under and between trees and large shrubs would be materially improved if the ground-surface were covered with woody vines and trailing shrubs. It will be necessary to prune out the leader or upright stem of many of these shrubs to encourage their spreading or horizontal growth.

- Juniperus chinensis* var. *procumbens* (3 feet).
- Juniperus Sabina* var. *tamariscifolia* (3 feet).
- Jasminum primulinum* (6 feet).

Sollya heterophylla (3 feet).
Hypericum calycinum (1 foot).
Hypericum Moserianum (3 feet).
 **Philadelphus mexicanus* (5 feet).
 **Trachelospermum jasminoides* (3 feet).
 †*Cuphea micropetala* (3 feet).
 **Cuphea ignea* (5 feet).
Clanthus puniceus (3 to 6 feet).
 **Streptosolen Jamesonii* (3 to 6 feet).
 **Plumbago capensis* (4 feet).
Myrtus communis (3 to 5 feet).
Cotoneaster microphylla (2 to 3 feet).
Cotoneaster horizontalis (2 to 3 feet).
 **Coprosma Baueri* (6 feet).
Evonymus radicans (2 feet).
Fuchsia Riccartonii (6 feet).
Leptospermum laevigatum (6 to 10 feet).
 **Tecoma capensis* (8 feet).
 **Reinwardtia trigyna* (4 feet).
 **Capparis spinosa* (3 feet).
 **Swainsona galegifolia* var. *albiflora* (6 feet).
Teucrium fruticans (6 feet).
Coronilla glauca (4 to 6 feet).
Melaleuca decussata (5 feet).
Cistus ladaniferus var. *maculatus* (2 to 4 feet).
Evonymus japonica var. *viridi-variegata* (4 feet).
Lantana Sellowiana (4 feet).
 **Lantana Camara* (4 to 6 feet).
Chorizema ilicifolium (5 feet).
 **Melanthus major* (4 feet).
 **Buddleia madagascariensis* (6 to 10 feet).
Jasminum humile (6 feet).
 **Solanum Rantonnetii* (6 feet).
Artemisia arborescens (5 feet).
Pentstemon cordifolius (5 feet).
 **Heliotropium* in variety (3 feet).
Pittosporum heterophyllum (3 feet).
 **Fuchsia fulgens* (5 feet).
 **Fuchsia corymbiflora* (6 feet).

Group X. Shrubs for quick effects (California).

Many shrubs are of rapid growth and if given heat and moisture will produce very quick effects. They are, therefore, especially suitable for screens, barriers, and nature effects in recently created gardens.

Myoporum laetum (8 to 12 feet).
Albizia lophantha (10 feet).
Leptospermum laevigatum (6 to 10 feet).
Acacia in variety (5 to 20 feet).
Melaleuca in variety (6 to 10 feet).
Spartium junceum (6 to 8 feet).
Casuarina in variety (10 to 25 feet).
 †*Tithonia diversifolia* (8 to 10 feet).
 **Wigandia caracasana* (8 to 10 feet).
 **Lantana* in variety (4 to 6 feet).
Cytisus in variety (6 to 8 feet).
 **Ichroma* in variety (8 to 10 feet).
 **Cassia* in variety (4 to 10 feet).
 **Buddleia* in variety (6 to 8 feet).
 **Cestrum* in variety (6 to 8 feet).
 **Plumbago capensis* (4 feet).
 †*Solanum Warscewiczii* (8 feet).
Dodonaea cuneata (6 to 8 feet).
 †*Bocconia frutescens* (8 feet).
 **Pittosporum undulatum* (10 to 15 feet).
Pittosporum eugenioides (10 to 15 feet).
Pittosporum crassifolium (10 to 15 feet).
 **Coprosma Baueri* (6 feet).
Veronica in variety (2 to 6 feet).
 **Sparmannia africana* (8 feet).
Coronilla glauca (4 to 6 feet).
 **Anthyllis Barba-Jovis* (4 to 6 feet).
 **Agonis flexuosa* (8 to 10 feet).
Fatsia japonica (6 feet).
Ligustrum ovalifolium (6 to 8 feet).
Escallonia in variety (6 to 10 feet).
Pimelea ferruginea (4 to 6 feet).
 †*Cuphea micropetala* (2 feet).
 **Streptosolen Jamesonii* (3 to 6 feet).
 **Grevillea Thelemanniana* (4 feet).
 **Atriplex Breweri* (6 feet).
 **Melanthus major* (4 feet).
Parkinsonia aculeata (8 to 10 feet).
Ceanothus arborea (8 feet).
 †*Muehlenbeckia platyclada* (6 feet).
 †*Clerodendron* in variety (6 feet).
 **Abutilon* in variety (8 feet).
 †*Carica quercifolia* (6 to 8 feet).

Agonis flexuosa, Schau. A tall shrub or tree from Austral.: lvs. lanceolate, smooth, dark green, the margins tinged with purple; fl.-heads white, axillary, surrounded by broad bracts; stamens long, numerous, white.

Group XI. Especially choice and neat shrubs.

Those shrubs which are free-flowering, compact, and possess interesting and well-arranged foliage, are

much in demand for the more intensively developed parts of a garden. They are particularly suitable for use on small home grounds, in formal gardens, and around the base-line of buildings.

Erica in variety (4 feet).
Diosma ericoides (3 feet).
 **Eugenia myrtifolia* (10 to 15 feet).
Choisya ternata (6 feet).
Daphne odora (3 feet).
 **Grevillea Thelemanniana* (4 feet).
Leptospermum scoparium var. *Nicholii* (4 to 6 feet).
Lonicera nitida (4 to 6 feet).
Berberis Darwinii (6 to 8 feet).
Abelia grandiflora (6 feet).
Pimelea ferruginea (4 to 6 feet).
 **Myrtus Ugni* (4 feet).
 †*Templetonia retusa* (3 feet).
 †*Asystasia bella* (3 feet).
Sollya heterophylla (3 feet).
 **Trachelospermum jasminoides* (3 feet).
 **Philadelphus mexicanus* (5 feet).
Michelia fuscata (6 feet).
 †*Heterocentron roseum* (1 foot).
 †*Dalacanthus nervosus* (2 feet).
Cassia artemisioides (4 feet).
Eugenia apiculata (8 feet).
Myrtus communis var. *microphylla* (2 to 3 feet).
 **Coprosma Baueri* (6 feet).
 **Cneorum tricoccon* (3 feet).
Cotoneaster horizontalis (2 to 3 feet).
Cotoneaster Franchetii (4 to 6 feet).
Cotoneaster microphylla (2 to 3 feet).
Ligustrum coriaceum (3 to 6 feet).
Ligustrum sinense (6 feet).
 **Genista monosperma* (6 to 8 feet).
 †*Rhodorhiza florida* (6 feet).
Aucuba japonica (4 feet).
Azara microphylla (8 feet).
Buxus in variety (2 to 8 feet).
Camellia japonica (8 feet).
Cytisus racemosus (2 to 3 feet).
Evonymus japonica var. *aureo-marginata* (6 to 8 feet).
Evonymus japonica var. *viridi-variegata* (4 feet).
Mahonia japonica (4 feet).
Melaleuca decussata (5 feet).
Nandina domestica (6 feet).
Osmanthus Aquifolium (4 feet).
Veronica in variety (2 to 6 feet).
 **Carissa grandiflora* (4 feet).
Hardenbergia monophylla (5 feet).
Jasminum primulinum (6 feet).
Metrosideros lucida (6 feet).
 **Tibouchina splendens* (5 feet).
 †*Salvia Sessei* (6 feet).
 **Fuchsia corymbiflora* (6 feet).
 **Fuchsia fulgens* (4 feet).
 **Fuchsia arborescens* (6 feet).
 **Duranta Plumieri* var. *alba* (3 to 6 feet).

Cneorum tricoccon, Linn., the spurge olive, is a native of S. En.: smooth, evergreen, 1 or 2 ft. high: lvs. narrow, entire, obtuse; fls. axillary; pedicels not adnate to the bracts. *Cneorum* is one of the Simarubaceae, or by recent authorities made the sole representative of the family Cneoraceae.

Group XII. Ornamental native shrubs.

While the native shrubs of California are not, in many cases, so effective and attractive for landscape purposes as most of the exotic material used, there is a growing interest in their ornamental qualities. They may be employed extensively to give character to the extremely naturalistic home grounds and to the typically Californian garden. Only the more ornamental species in general cultivation are listed below.

Carpenteria californica (6 to 8 feet).
Ceanothus thyrsiflorus (8 feet).
Photinia arbutifolia (8 to 10 feet).
Lyonothamnus floribundus var. *asplenifolius* (15 to 20 feet).
Prunus ilicifolia var. *integrifolia* (10 to 15 feet).
Arbutus Menziesii (10 to 20 feet).
Ceanothus arboreus (8 to 10 feet).
Ceanothus spinosus (6 to 8 feet).
Parkinsonia aculeata (8 to 10 feet).
Garrya Fremontii (6 feet).
Romneya Coulteri (6 feet).
Ribes speciosum (4 feet).
Vaccinium ovatum (3 feet).
Mahonia Aquifolium (4 feet).
Rhamnus californica (8 to 10 feet).
Rhus integrifolia (6 feet).
Rhus ovata (6 to 8 feet).
Rhamnus crocea var. *ilicifolia* (4 feet).
Umbellularia californica (15 to 30 feet).
Cercocarpus parvifolius (8 feet).
 **Gaultheria Shallon* (2 feet).

Arctostaphylos in variety (6 feet).
Fremontia californica (8 feet).
Calycanthus occidentalis (6 feet).
Dendromecon rigidum (6 feet).
 **Lavatera assurgentiflora* (6 feet).
 **Mimulus glutinosus* (4 feet).

JOHN WM. GREGG.
 R. T. STEVENS.

Vines for California.

In countries where there is a maximum of sunlight, vines become a most important class of plant-material. The many vines used in California are roughly divided into classes according to the climatic divisions of the state. Tropical and semi-tropical evergreen vines find most favor in southern California, where gorgeous coloring and luxurious growth appear most in harmony with the landscape; while the half-hardy evergreens and the choicest deciduous vines are most suitable for use along the central California coast. On the other hand, the vine which loses its foliage in winter finds the greatest favor in the interior sections of the state, although such few evergreens as withstand several degrees of frost are often employed for decorative purposes. When very quick effects are wanted, the annual vine is often used.

All vines except those clinging to rough surfaces need substantial support, while most vines require a certain amount of thinning and training. The tendency is to neglect the plant after it is once established and allow it to form thick unsightly masses of stems near the top of the support, thereby destroying such decorative beauty as the vine may possess. Vines should not be "headed back" or heavily pruned unless the plant is to be renovated, as a coarse rank growth is encouraged. If possible, choose strong stems as leaders and train in a fan-like manner so as finally to cover the desired area. Spring-flowering vines should be pruned soon after blooming, while summer- and fall-flowering vines may be thinned in the spring. The foliage of evergreen vines may be best reduced by careful selective thinning immediately after a blooming period. Always begin to train a vine as soon as possible; do not wait for it to begin to climb.

No climbing roses have been included in the following lists, as it is felt that they should be considered as a separate class of plant-material. Such vines as are not marked with "D" or "A" are evergreen, while those without an "o" or "x" are hardy. D=deciduous; A=annual; o=not resistant to frost; x=resistant to 10° to 12° of frost.

1. Vines which cover objects and surfaces densely.

The vines in this list have a tendency to cover their supports entirely, making a dense screen and thereby destroying architectural lines.

D— <i>Actinidia chinensis</i> .	x— <i>Pandorea australis</i> .
D— <i>Akebia quinata</i> .	o— <i>Pandorea Brycei</i> .

 x—*Vitis* (*Cissus*) *capensis*.

D—*Wisteria chinensis*.
 D—*Wisteria multi-juga*.

2. Vines producing light open tracery.

Vines to be ornamental should decorate and not entirely cover. Their chief purpose is to soften and partially break hard architectural lines. It is the contrast between foliage and background which produces decorative effect. Vines of this section are especially good for columns, walls, and frames.

o— <i>Abrus precatorius</i> .	x— <i>Hoya carnosa</i> .
D— <i>Antigonon leptopus</i> .	x— <i>Jasminum azoricum</i> .

x— <i>Dioclea glycinoides</i> .	x— <i>Pyrostegia venusta</i> .
o— <i>Dipladenia hybrida</i> .	Solanum <i>jasminoides</i> .
a— <i>Eccremocarpus scaber</i> .	x— <i>Solanum Seaforthianum</i> .
x— <i>Hardenbergia Comptoniana</i> .	Sollya <i>heterophylla</i> .
Hedera <i>helix</i> .	o— <i>Sigmaphyllon ciliatum</i> .
o— <i>Hidalgia Werckleii</i> .	o— <i>Sigmaphyllon littorale</i> .
	o— <i>Thunbergia grandiflora</i> .
	x— <i>Trachelospermum jasminoides</i> .

3. Vines as ground-covers on slopes, embankments, and under trees.

Vines require little care, hold the soil and make a permanent effect in those situations where the soil is too poor or too shady to maintain a satisfactory lawn.

Bignonia <i>Unguis-cati</i> .	Mesembryanthemum <i>cordifolium</i> .
x— <i>Duchesnea indica</i> .	Mesembryanthemum <i>roseum</i> .
Fragaria <i>californica</i> .	Muehlenbeckia <i>chilensis</i> .
Fragaria <i>chiloensis</i> .	Muehlenbeckia <i>complexa</i> .
Hedera <i>helix</i> .	x— <i>Pelargonium peltatum</i> .
a— <i>Humulus japonicus</i> .	D— <i>Senecio mikanioides</i> .
x— <i>Jasminum primulinum</i> .	Sollya <i>heterophylla</i> .
x— <i>Lantana Camara</i> .	A— <i>Tropæolum majus</i> .
Lantana <i>Sellowiana</i> .	Vinca <i>major</i> .
Lippia <i>canescens</i> .	Vinca <i>minor</i> .
Lonicera <i>japonica</i> var. <i>Halliana</i> .	x— <i>Vitis</i> (<i>Cissus</i>) <i>capensis</i> .
x— <i>Lotus Bertholetii</i> .	

4. Vines for stone, plaster, and brick surfaces.

Because of their various ways of clinging to rough surfaces, these vines need no support. They should not be grown on wood surfaces which are to be painted.

D— <i>Bignonia capreolata</i> .	Hedera <i>helix</i> .
Bignonia <i>Unguis-cati</i> (<i>B. Tweediana</i>).	Hedera <i>helix</i> var. <i>chrysocarpa</i> .
x— <i>Cissus striata</i> .	D— <i>Parthenocissus quinquefolia</i> .
x— <i>Clytostoma purpureum</i> .	D— <i>Parthenocissus quinquefolia</i> var. <i>Engelmannii</i> .

Evonymus <i>radicans</i> var. <i>roseo-marginata</i> .	
Ficus <i>pumila</i> .	
Ficus <i>pumila</i> var. <i>minima</i> .	

5. Vines for quick effects.

Useful to obtain mature effects in gardens. Rapid-growing deciduous vines are especially desirable for porches, pergolas, and arbors located in the large interior valleys.

D— <i>Actinidia chinensis</i> .	D— <i>Ipomœa setosa</i> .
D— <i>Aristolochia macrophylla</i> (<i>A. Sipho</i>).	x— <i>Jasminum primulinum</i> .
Bignonia <i>Unguis-cati</i> (<i>B. Tweediana</i>).	x— <i>Lantana Camara</i> .
D— <i>Boussingaultia basseloides</i> .	Lathyrus <i>splendens</i> .
x— <i>Buddleia madagascariensis</i> .	Lonicera <i>japonica</i> var. <i>Halliana</i> .
D— <i>Campsis radicans</i> .	Maurandia <i>Barclaiana</i> .
D— <i>Clematis montana</i> .	Melothria <i>punctata</i> .
D— <i>Clematis paniculata</i> .	x— <i>Pandorea australis</i> .
Cobæa <i>scandens</i> .	o— <i>Pandorea Brycei</i> .
x— <i>Dolichos lignosus</i> .	Passiflora <i>cærulea</i> .
x— <i>Dolichos lignosus</i> var. alba.	Passiflora <i>cærulea</i> var. alba.
A— <i>Humulus japonicus</i> .	o— <i>Passiflora edulis</i> .
F— <i>Humulus lupulus</i> .	x— <i>Passiflora manicata</i> .
D— <i>Ipomœa Learii</i> .	x— <i>Passiflora mollissima</i> .

o—*Passiflora racemosa* (P. princeps).
 x—*Passiflora tubiflora*.
 x—*Pelargonium peltatum*.
 x—*Phedranthus buccinatus*.
 D—*Phaseolus Caracalla*.
 x—*Philadelphus mexicanus*.
 D—*Pueraria hirsuta*.
 x—*Salpichroa rhomboidea*.

D—*Sechium edule*.
 D—*Senecio mikanioides*.
 Solanum jasminoides.
 D—*Solanum Wendlandii*.
 o—*Solandra guttata*.
 x—*Tecoma capensis*.
 D—*Thunbergia alata*.
 o—*Thunbergia coccinea*.
 A—*Tropaeolum majus*.

x—*Streptosolen Jamesonii*.
 x—*Tecoma capensis*.
 D—*Tropaeolum majus*.

Vinca major.
Vinca major, variegated.
Vinca minor.

9. Vines for pergolas and arbors.

For this purpose vines should not be allowed to make too heavy top growth and they should be so trained that a certain amount of their foliage is pendent.

D—*Antigonon leptopus*.
 D—*Aristolochia macrophylla* (A. Siph).
 o—*Aristolochia elegans*.
 Bignonia Unguis-cati (B. Tweediana).
 x—*Bougainvillea braziliensis*.
 o—*Beaumontia grandiflora*.
 D—*Clematis montana*.
 D—*Clematis paniculata*.
 x—*Clytostoma purpureum*.
 x—*Diolea glycinoides*.
 Gelsemium sempervirens.
 x—*Hardenbergia Comptoniana*.
 Hederia colchica (H. Rægnieriana).
 Hederia helix.
 Hederia helix var. chrysocarpa.
 o—*Hidalgia Wercklei*.
 A—*Humulus japonicus*.
 x—*Jasminum azoricum*.
 x—*Jasminum floribundum*.
 x—*Jasminum grandiflorum*.
 x—*Jasminum nitidum*.
 x—*Jasminum officinale*.
 x—*Jasminum primulinum*.
 x—*Jasminum rigidum* (J. ligustrifolium).
 x—*Lonicera Hildebrandiana*.
 Lonicera japonica var. Haliana.
 D—*Mandevilla suaveolens*.
 Muehlenbeckia complexa.
 x—*Pandorea jasminoides*.
 x—*Pandorea jasminoides* var. alba.
 o—*Pandorea Brycei*.
 D—*Periploca græca* (Silk Vine).
 x—*Phædranthus buccinatus*.
 x—*Philadelphus mexicanus*.
 x—*Pithecoctenium cynanchoides*.
 x—*Pithecoctenium muricatum*.
 o—*Solandra guttata*.
 Solanum jasminoides.
 x—*Solanum Seafortianum*.
 D—*Solanum Wendlandii*.
 x—*Stauntonia hexaphylla*.
 o—*Stephanotis floribunda*.
 o—*Stigmaphyllon ciliatum*.
 x—*Tecoma capensis*.
 o—*Thunbergia grandiflora*.
 x—*Vitis* (Cissus) capensis.
 x—*Vitis Romaneti*.
 D—*Wisteria chinensis*.
 D—*Wisteria multijuga*.
 D—*Wisteria multijuga* var. alba.

10. Foliage vines for California.

Many vines are especially ornamental because of their foliage effects. Those with smooth bright green closely arranged leaves are most desirable.

D—*Actinidia chinensis*.
 D—*Ampelopsis arborea*.
 D—*Aristolochia macrophylla* (A. Siph).
 x—*Asparagus asparagoides*.
 x—*Cissus striata*.
 x—*Clytostoma callistegioides*.
 Cobæa scandens.
 x—*Dolichos ligustris*.
 Evonymus radicans.
 Ficus pumila.
 Gelsemium sempervirens.
 A—*Humulus japonicus*.
 x—*Jasminum azoricum*.
 x—*Jasminum gracillimum*.
 x—*Jasminum rigidum* (J. ligustrifolium).
 x—*Pandorea australis*.
 x—*Pandorea jasminoides*.
 o—*Passiflora edulis*.
 o—*Passiflora laurifolia*.
 o—*Passiflora ligularis*.
 x—*Phædranthus buccinatus*.
 D—*Pueraria hirsuta*.
 D—*Senecio mikanioides*.
 x—*Serjania fuscifolia*.
 x—*Solanum Seafortianum*.
 D—*Solanum Wendlandii*.
 x—*Stauntonia hexaphylla*.
 o—*Thunbergia grandiflora*.
 x—*Vitis* (Cissus) antarctica.
 x—*Vitis* (Cissus) capensis.
 x—*Vitis* (Cissus) hypoglauca.
 x—*Vitis* (Cissus) rhombifolia.

Millettia megasperma, Benth., the "evergreen wisteria" from Austral. is a promising plant in California; woody climber; lfts. 7-13, obovate or obovate-oblong; fls. purple, in racemes 4-6 in. long which comprise a terminal panicle.

JOHN WM. GREGG.

R. T. STEVENS.

KATHERINE D. JONES.

6. Free-flowering vines for California.

Many vines produce only foliage effects or bloom but once a year. The vines in this list bear flowers more or less continuously. They are especially suitable for arbors and trellises in the flower-garden.

o—*Allamanda cathartica* var. Hendersonii.
 D—*Antigonon leptopus*.
 o—*Beaumontia grandiflora*.
 x—*Bougainvillea braziliensis*.
 x—*Bougainvillea glabra*.
 x—*Bougainvillea spectabilis* var. lateritia.
 Cardiospermum hirsutum.
 x—*Chorizema ilicifolium*.
 A—*Clitoria Ternatea*.
 x—*Clytostoma callistegioides*.
 Cobæa scandens.
 x—*Dolichos ligustris*.
 x—*Dolichos ligustris* var. alba.
 x—*Hardenbergia Comptoniana*.
 x—*Jasminum azoricum*.
 x—*Jasminum floribundum*.
 x—*Jasminum gracillimum*.
 x—*Jasminum grandiflorum*.
 x—*Jasminum*, Maid of Orleans.
 o—*Jasminum nitidum*.
 x—*Jasminum simplicifolium*.
 Jasminum Sambac, Grand Duke.
 x—*Lantana Camara*.
 Lantana Sellowiana.
 Lathyrus latifolius var. albus.
 Lathyrus splendens.
 Lonicera japonica var. Haliana.
 Lonicera sempervirens.
 D—*Manettia bicolor*.
 x—*Pandorea jasminoides*.
 x—*Pandorea jasminoides* var. alba.
 x—*Passiflora militaris*.
 o—*Passiflora racemosa* (P. princeps).
 x—*Pelargonium peltatum*.
 x—*Phædranthus buccinatus*.
 D—*Phaseolus Caracalla*.
 x—*Pithecoctenium muricatum*.
 x—*Plumbago capensis*.
 x—*Pyrostegia venusta*.
 o—*Schubertia grandiflora*.
 o—*Solandra grandiflora*.
 Solanum jasminoides.
 x—*Solanum Seafortianum*.
 D—*Solanum Wendlandii*.
 x—*Sollya heterophylla*.
 o—*Stephanotis floribunda*.
 o—*Stigmaphyllon ciliatum*.
 x—*Swainsona galegifolia* var. albiflora.
 x—*Tecoma capensis*.
 o—*Thunbergia grandiflora*.
 x—*Trachelospermum jasminoides*.
 D—*Tropaeolum majus*.

7. Vines somewhat resistant to shade.

Good for courts, north sides of buildings, under trees and on shady slopes.

x—*Asparagus asparagoides*.
 x—*Asparagus plumosus*.
 x—*Chorizema ilicifolium*.
 x—*Clianthus puniceus*.
 x—*Clytostoma callistegioides*.
 Ficus pumila.
 Ficus pumila var. minima.
 Hederia colchica (H. Rægnieriana).
 Hederia helix.
 x—*Hoya carnea*.
 x—*Jasminum azoricum*.
 x—*Jasminum gracillimum*.
 x—*Jasminum primulinum*.
 x—*Linaria cymbalaria*.
 Lippia canescens.
 D—*Micromeria Chamissonis*.
 x—*Pandorea australis*.
 D—*Parthenocissus quinquefolia*.
 D—*Parthenocissus tricuspidata*.
 o—*Quisqualis indica*.
 D—*Senecio mikanioides*.
 x—*Solanum Seafortianum*.
 Sollya heterophylla.
 o—*Stephanotis floribunda*.
 o—*Thunbergia laurifolia*.
 x—*Trachelospermum jasminoides*.
 Tradescantia virginiana.
 Vinca major.
 Vinca minor.
 x—*Vitis* (Cissus) antarctica.
 x—*Vitis* (Cissus) capensis.
 x—*Vitis* (Cissus) rhombifolia.

8. Vines somewhat resistant to drought.

Vines are largely natives of cool moist forest floors where the soil is deep and loose, but the following will endure a certain amount of drought and hard clay soils.

Bignonia Unguis-cati (B. Tweediana).
 x—*Bougainvillea*.
 x—*Buddleia madagascariensis*.
 x—*Diolea glycinoides*.
 x—*Dolichos ligustris*.
 Evonymus radicans.
 Ficus pumila.
 Hederia helix.
 x—*Jasminum primulinum*.
 x—*Lantana Camara*.
 x—*Lantana Sellowiana*.
 Lathyrus latifolius.
 Lathyrus splendens.
 Lippia canescens.
 Lonicera japonica var. Haliana.
 Lonicera Periclymenum var. belgica.
 Mesembryanthemum roseum.
 Muehlenbeckia complexa.
 x—*Pandorea australis*.

 Solanum jasminoides.
 Sollya heterophylla.

PLÁTANUS (its ancient Greek name). *Platanocæx*. PLANE-TREE. BUTTONWOOD. Ornamental trees with handsome dense foliage, often planted as shade and street trees.

Deciduous, with the bark exfoliating in thin plates, but at the base of older trunks the bark is persistent, of darker color and furrowed: stipules conspicuous, usually connate into a tube, with spreading lf.-like margin; petiole with the enlarged base inclosing the axillary bud: lvs. palmately lobed, covered densely with stellate hairs when young; fls. monoecious, in dense globular heads, staminate and pistillate similar, but on separate peduncles; sepals and petals 3-8; staminate with 3-8 stamens, pistillate with 3-8 pistils with elongated styles; fr.-heads consisting of numerous narrowly obconical, 1-seeded nutlets surrounded at the base by long hairs.—Six or 7 species are known in N. Amer., south to Mex. and from S. E. Eu. to India.

The planes are handsome trees with large and

palmately lobed leaves and small greenish flowers in drooping heads, followed by similar heads of fruits remaining on the branches during the winter. The smooth light-colored often almost creamy white bark of the branches and limbs, usually mottled by darker blotches of the older bark, which peels off in large thin

3061. *Platanus racemosa*.
($\times \frac{1}{2}$)

plates, gives the tree a very characteristic appearance in winter, while in summer the plane-tree, with its large head of dense bright green foliage and with its massive trunk is a beautiful and majestic shade tree. The native *P. occidentalis* is hardy North and *P. acerifolia* and *P. orientalis* hardy as far north as Massachusetts, while the southwestern and Mexican species cannot be cultivated in the North. From time immemorial, the oriental plane, which was well known to the ancient Greek writers, has been famous for the large size it attains—trunks of 30 feet in diameter and more are reported to exist—and has been planted as a shade tree in western Asia and southern Europe, and today it is still one of the favorite street trees throughout the temperate regions of Europe. It has also been recognized in this country as one of the best street trees, even to be preferred to the native plane, which, unfortunately, suffers from the attacks of a fungus, *Glæosporium nervisequum*, while the oriental is not injured by it. The plane-trees stand pruning—even severe pruning—well. To what extent they are sometimes pruned in European cities without losing their vitality is shown in an interesting illustration in "Forest Leaves," Vol. III, p. 97. They are also easily transplanted even as larger trees. They grow best in a deep and rich moist soil. Propagation is by seeds sown in spring and only slightly covered with soil and kept moist and shaded; also by cuttings of ripened wood and by greenwood cuttings under glass in June taken with a heel, and sometimes by layers. Varieties are also sometimes grafted in spring on seedlings of one of the species. The stellate hairs of the young leaves when detached by the wind, sometimes float in great quantities in the air and are liable to cause irritation and sometimes inflammation of the mucous membranes of the eye, nose, and mouth. But as this is likely to occur only during a very limited period late in spring it can hardly be considered as a serious objection to the use of platanus as a street tree.

A. *Fr.-heads 3 or more, in pendulous racemes.*

B. *Lobes 5-7, dentate or lobed.*

orientalis, Linn. ORIENTAL PLANE. Tree, to 80 ft., with usually very broad and round head on a comparatively short trunk: bark of dull grayish or greenish white color: stipules small, usually with entire margin: lvs. usually broadly cuneate at the base, deeply 5-7-lobed, rarely 3-lobed, with the sinuses reaching almost to or below the middle; lobes longer or much longer than broad, coarsely toothed or entire, glabrous or nearly so at maturity, 4-8 in. long: fr.-heads 2-4 on long, drooping stalks, bristly, the nutlets narrowed at the apex into a persistent style to 2 lines long. May. S. E. Eu. to India. G.F. 4:91. G.C. III. 23:25, 27; 29:363. Gn. 1, p. 550; 20, pp. 369, 371, 373. F.S.R. 2, pp. 75, 77. F.E. 24:69. G.W. 14, pp. 688, 689. Var. *digitata*, Janko (*P. umbraculifera*, Hort., var. *laciniata*, Hort.). Lvs. cuneate or truncate or cuneate at the base, deeply 5-lobed, with narrow, elongated, coarsely toothed lobes. Gn. 1, pp. 572, 573; 20, p. 371. F.E. 18, p. 718, pl. 89. Var. *cuneata*, Loud. (*P. cuneata*, Willd.). Often shrubby: lvs. short-stalked, smaller, usually deeply 3-lobed and cuneate, with narrow-toothed lobes. Gn. 1, p. 618; 20, p. 371. G.C. III. 29:363.—The true oriental plane is rare in cult., the tree usually planted under this name being *P. acerifolia*.

BB. *Lobes 3-5, usually entire.*

racemosa, Nutt. (*P. californica*, Benth.). Fig. 3061 (adapted from Pacific R. R. Report). Tree, to 100 or 120 ft., with a trunk often divided into several sts.: lvs. usually cordate or truncate, deeply 3-5-lobed, thick and firm, deep green above, paler beneath and covered with a pale tomentum, 6-10 in. diam.; lobes ovate-lanceolate, entire or sometimes remotely or sinuately toothed: fr.-heads bristly or rather smooth, sessile, 2-7; nutlets tomentose while young, becoming glabrous. S. Calif. and Low. Calif. S.S. 7:328.

AA. *Fr.-heads 1 or 2, rarely 3.*

acerifolia, Willd. (*P. orientalis* var. *acerifolia*, Ait. *P. intermedia*, *P. integrifolia* and *P. macrophylla*, Hort. *P. damascena*, Dode). LONDON PLANE. Fig. 3062. Probably hybrid between *P. orientalis* and *P. occidentalis* and intermediate between the two, sometimes resembling

3062. *Platanus acerifolia*. ($\times$ about $\frac{1}{2}$)

more the one and sometimes more the other parent. Tree, to 100 ft.: lvs. 3-5-lobed, usually truncate or broadly cuneate at the base, the lobes broadly triangular, coarsely toothed, the middle lobe as long or slightly longer than broad: fr.-heads usually 2, rarely 3, bristly or sometimes scarcely so. Of garden origin. G.C. III. 29:363. Gn. 1, p. 588; 20, p. 371 and probably 1, p. 486, and 20, p. 370 (as *P. occidentalis*). F.E. 24:69 (as *P. orientalis*). Var.

pyramidalis, Jaen. (*P. pyramidalis*, Bolle). Of pyramidal habit: lvs. usually 3-lobed, often longer than broad, with usually rounded base. Var. *tubifera*, Jaen. (*P. superba*, Hort.). With very conspicuous elongated, tubular stipules. There are also some forms with variegated lvs. Var. *Süttneri*, Hort., with the lvs. spotted and marked white, and var. *Kelseyana*, Schneid. (var. *aureo-variegata*, Hort.), with yellow-variegated lvs.—The London plane is more generally planted under the name of the oriental plane than the true *P. orientalis*. It resembles in foliage more the American plane and is of more pyramidal habit than the oriental plane, which in its typical form has a broad head, with wide-spreading branches, deeply divided, 5-7-lobed lvs., and the fr.-heads usually in 3's and 4's. It is somewhat harder than the oriental plane.

occidentalis, Linn. BUTTONWOOD. BUTTONBALL. AMERICAN PLANE-TREE. Also wrongly called SYCAMORE. Fig. 3063. Large tree, attaining 130 or occasionally 170 ft., with a round-topped oblong or

3063. *Platanus occidentalis*. ($\times \frac{1}{4}$)

broad head and with a trunk 10 ft. or exceptionally more in diam., often of considerable height: bark of limb and branches of very light often almost creamy white color, at the base of the trunks dark brown, fissured: stipules large, with toothed margin: lvs. as broad or broader than long, truncate or cordate, rarely cuneate at the base, usually 3-, sometimes 5-lobed, with shallow sinuses; lobes shorter than broad, coarsely toothed or entire, floccose-tomentose when young, at maturity only pubescent on the veins beneath, 4-9 in. broad: fr.-heads solitary, rarely in 2's, on 3-6-in.-long peduncles, about 1 in. across or more, comparatively smooth at length; nutlets with obtuse apex, with the rest of the style $\frac{1}{16}$ in. long or shorter. May. Maine to Ont. and Minn., south to Fla. and Texas. S.S. 7:326, 327. G.F. 2:354, 355; 9:55. Em. 1:261, 263. Gng. 4:343. Mn. 3, p. 69; 5, pp. 205, 209.—The most massive and perhaps the tallest of all deciduous trees of N. Amer. and an excellent street and park tree where it is not injured by fungous diseases. A doubtful variety is var. *hispanica*, Wessm. (*P. hispanica*, Lodd.). Lvs. large, 3-5-lobed, with very shallow sinuses, coarsely toothed, usually cordate at the base. Gn. 1, p. 588; 20, p. 370.—The *P. densicoma*, Dode (B.S.D. 1908:68), described as having usually truncate or broadly cuneate lvs. and 1-3 heads with acutish nutlets is probably not different from *P. occidentalis* or may belong to *P. acerifolia*.

P. vulgaris, Spach, comprises all species of the genus.—*P. Wrightii*, Wats. Tree, to 80 ft., often divided into several sts.: lvs. usually cordate or truncate, deeply 3-7-lobed, with lanceolate, acuminate, entire or dentate lobes, tomentose beneath or nearly glabrous at length, 6-8 in. long; fr.-heads racemose, rather smooth, each on a short stalk. New Mex. and Ariz. to Calif. S.S. 7:329.

The other species, as *P. mexicana*, Moric., which is sometimes

planted as a street tree in Mex., *P. Lindeniana*, Mart. & Gal., and *P. glabrata*, Fern., all natives of Mex., are not yet intro.

ALFRED REHDER.

PLATONIA (from a personal name). *Guttiferæ*. Trees, little known as yet in cult.: lvs. leathery, closely and finely feather-veined: fls. large, rose, solitary, terminal, perfect; sepals 5, imbricate; petals 5, much larger than the calyx, scarcely convolute into an ovoid corolla; stamens 5; ovary 5-celled: fr. a fleshy indehiscent 5-celled edible berry. Two species from Brazil. *P. insignis*, Mart. Large tree: lvs. coriaceous, oblong, acute: fls. solitary, terminal, showy; sepals suborbiculate, 2 outer smaller; petals broad-ovate, rose outside, white inside; ovary ovoid: berry subglobose or oval. Brazil. Intro. and distributed by the U. S. Dept. of Agric.

PLATYCARYA (Greek for *broad*, and *nut*; alluding to the shape of the fruit). Syn., *Fortunæa*. *Juglandaceæ*. A monotypic genus distinguished from all other *Juglandaceæ* by its fertile fls. forming an upright cone-like spike. Small deciduous tree: the branches with solid pith: winter buds with imbricate scales: lvs. odd-pinnate, similar to those of *Carya Pecan*, but smaller: staminate catkins axillary; pistillate terminal, solitary: fr. a small, winged nut in the axils of densely imbricated, rigid and sharply pointed lanceolate bracts forming a terminal upright cone. Rarely cult. and not hardy north of the Middle states. It has graceful foliage, but its ornamental value is not great. Prop. by seeds and by layers, probably also by grafting on *Carya*.

strobilicæa, Sieb. & Zucc. (*Fortunæa sinensis*, Lindl.). Small tree, with upright glabrous branches: lvs. 8-12 in. long; lfts. 9-17, sessile, oblong-lanceolate, falcate, acuminate, doubly serrate, pubescent only on the midrib beneath, 3-4 in. long: fr.-bearing cone about 1-1½ in. long, oval, brown. Summer. Japan, China. S.Z. 2:149. F.S. 4, p. 326b. R.H. 1888, p. 88. J.H.S. 1846, p. 151. S.I.F. 1:17. ALFRED REHDER.

PLATYCERIUM (Greek, *broad horn*; alluding to the shape of the lvs.). *Polypodiaceæ*. STAG-HORN FERN. An anomalous genus of ferns with irregularly lobed thick lvs. with the sori forming irregular patches over one or both surfaces. The sterile lvs. are flat, rounded expansions closely adherent in layers to the substratum. In their native forests these ferns grow to the surface of trees and old plants and often form enormous nests. A few kinds of *Platycerium* are offered for sale in Amer. European growers list others, new ones appearing from time to time, but the whole group is grown in America only as specimens in large collections. The word "disk," as used below, refers to the widest unbranched portion of the fertile frond.

The stag-horn ferns are amongst the most beautiful and distinct of ferns—perhaps the most striking of all—because of their noble antlered appearance and their epiphytal habit. They have two kinds of fronds, barren and fertile, the former being rounded disks which clasp the tree trunk, while the fertile fronds generally hang down and look like antlers. Occasionally the barren fronds are more or less antlered, as in *P. grande*, but never give so perfect a suggestion as do the fertile fronds. The species are all tropical, except *P. alcornoe*, which is therefore the easiest to grow and the commonest in cultivation. This species can endure a night temperature of 50° F. or even less. The glory of the genus, however, is *P. grande* (Fig. 3064). The barren fronds are exceptionally large, rounded, and wavy margined at the base, deeply cut above, forming an erect or arching background to the pendent fertile fronds, which fork more times and have much narrower segments than the barren fronds. Unfortunately this

is the only species that does not produce suckers at the roots, by which all the others are easily propagated. It alone must be raised from spores, a long and anxious process. The only kind that has an erect and rigid habit is *P. Hillii*, which therefore is grown in pots while all the others may be grown on a block of wood, and some in baskets. *P. biforme* differs from all others in having a separate and specialized structure on which the sori are borne, the other kinds bearing their spore-masses on the under surface of the fertile fronds at or near the last forks. *P. biforme*, though it has been advertised, is probably nowhere in cultivation in the world. There is an improved form of the common type known as *P. alciorne* var. *majus*, which is stronger-growing and has thicker fronds, enabling it to endure a drier atmosphere. It is therefore one of the best, if not the best, for exhibition purposes. At the other extreme from the slender grace of *P. alciorne* and the rest is the bold and broad style of *P. æthiopicum*. The only one which bears no resemblance to antlers is *P. angolense*. All the species require a moist atmosphere, though the humidity should be reduced during the winter. With the exception of *P. alciorne* they all demand a high temperature. All need perfect drainage, and in winter they should not have too much direct syringing, for they need a slight rest and are likely to spot or damp-off if water remains on the foliage too long. *P. æthiopicum* is said to be particularly sensitive. Stag-horn ferns are often grown on pieces of tree-fern stem. They are fastened to such support or to a board by means of wire, having first furnished the roots with a slit piece of peat for roothold and some sphagnum moss, to which may be added a little bone-meal for food and some charcoal for drainage. A little moss may be added every year or two. Eventually the barren fronds will entirely cover this material and the plants should then be left undisturbed for years. A stag-horn fern, with antlers spreading 6 or 8 feet, is a sight never to be forgotten. (W. H. Taplin and F. L. Atkins.)

A. *Plants not forked like a stag-horn.*

angolense, Welw. (*P. æthiopicum* var. *angolense*, Welw.). Fertile lvs. wedge-shaped in outline and merely wavy at the margin, not divided into lobes. It is also distinct by reason of felt-like covering of rust-colored wool on the lower side of the lvs. Barren lvs. large, erect; fertile lvs. attaining a length of 18 in. and a width of 9 in. at the top; spore-mass nearly as broad as the lf. Angola (W. Afr.). G.C. III. 23:155 (repeated in 28:444).

AA. *Plants resembling a stag-horn.*

B. *Sori borne on a special receptacle.*

biforme, Blume. According to Blume's plate and description, this differs from all other kinds in having the spores borne on a special appendage, which is kidney-shaped and attached below the first fork. Blume says there are 2 such appendages; that the barren lvs. are roundish, entire below, lobed above: fertile lvs. 3-5 ft. long, many times forked, pale green. Java.—The fertile lvs. of *P. biforme* are said to grow 15 ft. long sometimes. The picture in Gn. 4, p. 295, labeled *P. biforme* seems to be distinct and anomalous, though somewhat like *P. grande*.

BB. *Sori borne on the last forks or near their base.*

C. *Barren lvs. stag-horn-like above.*

D. *Fertile lvs. in pairs.*

E. *Plants glabrous or nearly so.*

grande, J. Smith. Fig. 3064. This may be readily distinguished from *P. alciorne* by its barren lvs., which are also stag-like, while those of *P. alciorne* are not. Barren lvs. stalkless; segms. blunt, spongy, pale green, tomentose; fertile lvs. in pairs, 3-6 ft. long; sori not at the base of every ultimate fork but against the

upper edge of the disk, with an infertile fork projecting beyond on either side. N. Austral. G.C. 1872: 1137; III. 8:97 (good, repeated in III. 10:698 and 28:433). Gng. 5:169 (same as A.F. 6:701). F. 1850:47 (same as F.S. 6, p. 156). Not G.M. 40:135, which is *P. æthiopicum*. Mn. 1, p. 77 (erroneously as *P. alciorne*).

EE. *Plants pubescent, with yellowish wool.*

Wállichii, Hook. As in *P. grande*, the sori are borne not at the base of the ultimate forks, but on a disk which is not squared off at its upper surface but rounded and projecting into the angle between the forks; sori roundish. Malay Penins. G.C. III. 28:435. Hook. Fil. Exot., pl. 97.

3064. *Platycerium grande*.

DD. *Fertile lvs. in 3's.*

Willinckii, Moore. Distinguished from *P. grande* by the sori, which nearly fill the last forks but do not approach the base of the sinus. The lvs. are thinly furnished with minute stellate hairs, at length glabrous and pale green. Moore says: "fertile fronds in 3's, elongate, pendent, with scarcely any disk, bipartite for about two-thirds of their length, one of the margins of each primary branch entire, the other bearing numerous lobes in about three series on a dichotomous plan." Strong features of this plant are the length, narrowness and acuteness of the forks, and also the narrowness of the "disk" or unbranched portion just below the primary forks. Java. G.C. II. 3:303 (repeated in III. 10:701 and 28:431). A.G. 15:111. Gn. 10, p. 383 (repeated in Gn. 30, p. 300).

CC. *Barren lvs. not stag-horn-like, entire or merely lobed.*

D. *Segms. and sinuses of the fertile lvs. very broad.*

æthiopicum, Hook. (*P. Stemmària*, Beauv.). Barren lvs. rounded; fertile lvs. 2-3 ft. long, clustered, pendent, twice dichotomous (not twice trichotomous, as some writers say): sorus a V-shaped patch surrounding the sinus. Guinea, Angola. Hooker's Garden Ferns, pl. 9. A.G. 15:111. G.M. 40:135 (erroneously as

P. grande).—The fronds are said to be covered below with a thin cottony down.

DD. *Segms. and sinuses narrow.*

E. *Unbranched portion of fertile lvs. very long and narrow.*

Hillii, Moore (*P. alciórne* var. *Hillii*). Barren lvs. like *P. alciórne*, but the fertile lvs. are erect, the unbranched portion longer, the forks more numerous and compact, the segms. shorter and more acute. Lvs. clustered thinly, covered when mature with white stellate hairs; sori in oval or roundish masses, not at the base of the sinus but near the base of each of the last segms. The upper third of the fertile lf. is "15-18 in. across, 3-parted, the central segms. with 1 or 2 side lobes near the apex, the 2 lateral segms. broader and twice or thrice forked into 5-10 ultimate lobes."—T. Moore. Queensland. G.C. II. 10:51, 428, 429. J.H. III. 32:497.

EE. *Unbranched portion of fertile lvs. moderately long.*

alciórne, Desv. Barren lvs. rounded, convex, wavy margined; fertile lvs. clustered, attaining 2-3 ft., 2-3 times dichotomous, the unforked portion erect, the segms. pendent, rather narrow and sharply cut, under surface covered with thin cottony down: sori in irregular masses filling the last forks and a space across their bases, shown in B.R. 262, 263 (as *Acrostichum alciórne*). Temp. Austral. A.G. 14:153; 15:111. Gn. 51, p. 259. G.C. III. 10:697. Not Mn. 1, p. 77, which is really *P. grande*.

Var. *majus*, Moore, is stronger-growing, more upright, and with thick, leathery, dark green lvs. According to F. L. Atkins, the fertile lvs. are more broadly cut than the type and seldom forked more than once. Polynesia. Veitch's Catalogue in 1873, p. 13.

WILHELM MILLER. R. C. BENEDICT.†

PLATYCLINIS (Greek, *broad bed*; in allusion to the clinandrium). *Orchidaceæ*. Epiphytic orchids, suitable for a warm greenhouse. These plants are by recent orchid students referred to *Dendrochilum*. In this account, the names under that genus are given in the parentheses.

Pseudobulbs small, closely crowded, each with a single, narrow, evergreen lf.: fls. borne in graceful,

compact-growing plants, requiring but little root-space. They are of easy culture and readily adapt themselves to either pot or basket culture, the latter being preferable for those with pendulous flower-scapes. The roots do not like being disturbed, but when repotting is necessary it is best to do it just after the flowering period. The compost should consist of equal parts chopped live sphagnum moss and clean peat fiber. The roots should be carefully distributed and the compost pressed gently but firmly in around them, leaving the surface slightly convex when finished. At least two-thirds of the space should be devoted to free drainage with potsherds or bits of charcoal. A shaded location and moist atmosphere, with a temperature of 60° to 65° F. by night and 70° to 75° by day, will afford them satisfactory growing conditions. They require a liberal supply of water at the roots, with occasional syringing overhead in bright weather when growing, and should never be allowed to remain long dry even when at rest. The plants frequently produce side growths from the old pseudobulbs, which may be removed after the growths are matured, leaving three or more of the old pseudobulbs attached to each piece, thus increasing the stock. When no natural break occurs, however, the plants may often be induced to break by slightly twisting, or notching the rhizome with a sharp knife, thereby retarding the flow of sap at that point. (Robert M. Grey.)

glumâcea, Benth. (*Dendrochilum glumâceum*, Lindl.). Fig. 3065. Pseudobulbs crowded, forming dense spreading masses, the young ones clothed with red scales: lvs. solitary, broadly lanceolate, tapering to a petiole which is inclosed by the sheath: peduncle from the top of the pseudobulb, slender, bearing a long drooping spike of small white fls.; sepals and petals spreading, oblong, acuminate; middle lobe of the labellum rotund, curved, base with 2 fleshy ridges. Spring. Philippines. B.M. 4853. G.C. III. 18:552. G.M. 48:385. Gn.W. 16:665.

filifórmis, Benth. (*Dendrochilum filifórmis*, Lindl.). Pseudobulbs crowded: lvs. linear-lanceolate: fl.-st. thread-like, bearing a long, pendulous raceme of small, pale yellow fls.; sepals and petals obovate; labellum cuneate-rotund, auriculate at the base. Summer. Philippines. I.H. 25:323 (as *Dendrochilum glumâceum*). G.F. 2:485.

Cobbiána, Hemsl. (*Dendrochilum Cobbiánum*, Reichb. f.). Lvs. oblong-lanceolate: fls. in a zigzag raceme, pale yellow, with an orange lip; sepals and petals triangular-oblong; labellum cuneate-fan-shaped, retuse. Nov., Dec. Philippines. O. 1914, p. 123.—This is offered in some catalogues under the name of *P. autumnalis*.

P. bárbifrons, Kränzl. Lvs. lanceolate, acute, 5-7 in. long, about 1 in. broad: racemes very slender, pendulous, many-fld.; fls. greenish white, about $\frac{1}{4}$ in. across; sepals and petals similar, ovate-lanceolate, acuminate; lip entire, obovate, apiculate. Sumatra. G.C. III. 31:366 (desc.).—*P. cucumerinum*, Hort. (*Dendrochilum cucumerinum*, Reichb. f.). Lvs. long-petiolate, oblong, 5-nerved, up to 5 in. long, less than $\frac{1}{2}$ in. wide: scape slender, exceeding lvs., with a pendulous raceme; fls. pellucid-green; sepals oblong, acute, $\frac{1}{2}$ in. long; petals similar, denticulate, lip 3-toothed. Philippines.—*P. latifolia*, Hemsl. Pseudobulbs 1-lvd.: lvs. elliptic-lanceolate, 10 in. long, 7-nerved: raceme many-fld., pendulous, on an erect scape; fls. greenish yellow; sepals triangular-lanceolate, acute, $\frac{1}{2}$ in. long; petals ovate-lanceolate, acute, denticulate; lip brown-striped. Philippines.

GEORGE V. NASH.

PLATYCÔDON (Greek, *platys*, broad, and *kodon*, bell; referring to the shape of the flower). *Campanulacæ*. Perennial smooth erect glaucous herbs, which are used in border planting.

Leaves sparse, often opposite or whorled, subsessile, dentate: fls. large, solitary or few at the ends of the branches; calyx-tube adnate, turbinate, 5-lobed; corolla campanulate, 5-lobed; stamens free from the corolla; ovary inferior, 5-celled: caps. obovoid, top

3065. *Platyclinis glumacea*.

drooping racemes 6-10 in. long, small and not showy, but the thread-like racemes arching from among the densely tufted green foliage give the plants a pleasing appearance; sepals and petals spreading; labellum 3-lobed; column short, with an erect-toothed clinandrium and a large, narrow, erect wing on each side of the clinandrium.—About 20 species in India, China, and the Malay Isls.

The several species of *Platyclinis* are all small com-

conical, loculicidal within the lobes of the calyx, 5-valved.—One species, E. Asia and Japan. This plant was first placed in *Campanula* by Jacquin, and later, by Schrader, in *Wahlenbergia*; and it is still sometimes cult. under these names. In 1830 it was made a separate genus (*Platycodon*) by A. DeCandolle. It is distinguished from *Campanula* by its broadly cup-shaped fls., the stamens dilated at the base, and the caps. opening at the top and not at the sides.

From *Wahlenbergia* it differs in the valves of the caps. being opposite to the calyx-lobes instead of alternate with them. Several supposed species have been described at different times, but there seems to be no doubt that the genus is distinctly monotypic and that all forms can be referred as forms of the type *P. grandiflorum*, which has been widely distributed and thereby greatly modified. It has been found in a wild state from Dahuria to Manchuria, in China, in Siberia, Korea, and Japan.

Platycodon requires a medium sandy loam, and does not succeed in either extremely stiff or sandy soils. It is particularly sensitive to ill-drained soils. Under suitable soil conditions it is perfectly hardy and will even stand considerable neglect. It is desirable to keep the stems tied during the season, for if once allowed to fall they can never be raised without breaking. In autumn the old stems should not be cut away, but the plant allowed to die off naturally; otherwise the crown may be injured. It can be propagated either by division or by seeding, the latter being more surely successful and therefore preferable; besides, a greater variety of flowers is obtained in this way. More care and skill are necessary in propagation by division, because of the fleshy rootstock. It is best accomplished in spring, when the plant is breaking into new growth.

One of the best single varieties of *P. grandiflorum* is "Die Fee," large and very free-flowering, sky-blue. Of the numerous semi-double and double sorts may be noted Goos & Koenemann's German introductions: Capri, deep blue, medium tall; Multiflora, with thickly set clear blue bells; Seidenball, lilac-purple, and the dark blue Vineta. Of French origin are Cloche bleue, navy blue, and Globe azuré, sky-blue. (Richard Rothe.)

grandiflorum, DC. (*Campanula grandiflora*, Jacq. *Wahlenbergia grandiflora*, Schrad.). CHINESE or JAPANESE BELLFLOWER. BALLOON FLOWER. Fig. 3066. Plant 1-2 ft. high, forming a dense, branching bush of upright habit: lvs. lanceolate or ovate-lanceolate, glabrous, unequally toothed: fls. large and open, attaining 3 in. diam., produced from tips of branches, inflated in the bud, hence sometimes called "balloon flower," corolla 5-lobed, blue, pale blue-white, or variegated. June, July. G.C. III. 28:223. J.H. III. 30:123; 54:331. F.S. 22:2332. B.M. 252. F.E. 15:647. G. 30:421. Gn.W. 6:713. R.B. 39:347. Var. *album*, Hort. A white-flowering form. Var. *autumnale*, Voss. (*P. autumnale*, Decne.). Later-flowering form from Man-

3066. *Platycodon grandiflorum*. (× $\frac{1}{3}$)

churia. Gn. 45, p. 462. R.H. 1848:361; 1858, p. 547. G. 2:211. H.F. 8:172. J.F. 3:250.

Var. *japonicum*, Hort. (*P. japonicum*, Hort.), is of stronger and bushier growth and freer-flowering. The fls. average $2\frac{1}{2}$ in. across; the inner and outer lobes alternate with one another, giving the fl. the appearance of a 10-pointed star.—This variety was first procured by Dreer in 1895 from Leonard Lille, Lyons, France, who offered it as a novelty that season. It proved to be a first-class and desirable sort and has been tested by Dreer since, who considers it one of the good hardy perennials.

Var. *Mariësii*, Hort. (*P. Mariësii*, Hort.). Originally intro. into England from Japan by Mariës, and supposed to be identical with var. *glaucom* of Siebold. It does not exceed 1 ft. in height: growth stouter and more compact: lvs. thicker than in the type: fls. are as large or larger than the type and varying in color from deep purplish blue to pale blue or lavender and white. G.C. III. 14:163. G.M. 37:35. J.H. III. 35:29; 63:152. Gn. 27:216; 45:462. A minor form of var. *Mariësii*, var. *nana*, Hort., is frequently offered in the trade as being dwarfer and more compact, with white or blue fls. Var. *sémi-duplex*, Hort. Two and one-half ft. high: fls. rich blue, darker veined, $2\frac{1}{2}$ -3 in. across, flattened, and with a second row of corolla-segms. G.M. 43:575. G.C. III. 28:223. Var. *sémi-plènum*, Hort. Fls. semi-double, and varying in color from purple to white; said to have been developed from var. *album*. Var. *striatum*, Hort. A garden form with blue or white fls., striped with white or blue.

ARNOLD V. STUBENRAUCH.
F. TRACY HUBBARD.†

PLATYCRATER (Greek, *platys*, broad, and *crater*, bowl; alluding to the broad enlarged calyx of the sterile fls.). *Saxifragaceæ*. A monotypic genus allied to *Hydrangea*. The species is a woody plant, with opposite serrate lvs. and white, comparatively large fls. in long-peduncled, loose cymes, the marginal ones sterile and with enlarged calyx; petals 4; stamens numerous: fr. a 2-celled many-seeded dehiscent caps. It is not hardy N. and of little decorative value. It thrives best in rather moist, porous soil and partly shaded position and is easily prop. by seeds, greenwood cuttings under glass, or layers.

arguta, Sieb. & Zucc. Prostrate shrub: lvs. oblong to oblanceolate, cuneate at the base, acuminate, glabrous except on the veins beneath, thin, light green, 3-6 in. long: cymes 3-10-fl., on a 1-2-in.-long peduncle; fls. slender-pedicelled, the sterile ones apetalous, 1 in. across, with broad, obtuse sepals; fertile smaller, with lanceolate sepals half as long as the oblong-ovate petals. July. Japan. S.Z. 1:27. Gt. 15:516. H.F. 1870:206. —Useful for rockwork in greenhouses.

ALFRED REEDER.

PLATYLEPIS (Greek, *broad scale*; presumably referring to the fact that the sepals are broad). *Orchidaceæ*. Terrestrial herbs with creeping rhizomes and ascending leafy sts., suitable for the warmhouse: lvs. petiolate, ovate or ovate-lanceolate, membranous: fls. narrow, shortly pedicelled, arranged in dense spikes; bracts ovate; sepals subequal, narrow, free, connivent round the column; lateral united at the base into a very short chin.; petals narrow, slightly cohering with the dorsal sepal into a hood; lip sessile at the base of the column, erect, channelled, broadly ventricose at the base, cohering with the margins of the column; limb very little dilated; column elongated, subterete, clinandrium oblong, erect behind the rostellum. About 6 species, Trop. and S. Afr. *P. australis*, Rolfe. Lvs. ovate, 2-4 in. long, 15-21-nerved: infl. erect scapes 6-12 in. long, bearing an oblong or elongated many-fl. raceme 2-5 in. long; fls. small, green, with the upper half of the lip white. S. Afr. *P. densiflora*, Rolfe. Differs from the preceding in having narrower sepals, the

lateral not reflexed in the middle, narrower petals, and a lip not constricted in the middle. Mascarene Isls. Both species have been intro. at Kew Gardens, but probably are not in general cult. Stovehouse plants.

F. TRACY HUBBARD.

PLATYLÔMA is a name for ferns of the genus *Pellaea* which have a narrow indusium and a broad sorus. For *P. Bridgesii* and *P. falcata*, see *Pellaea*.

PLATYSTÈMON (Greek, *broad, thread*; referring to the broadened filaments). *Papaveraceæ*. Low annual herbs generally branched at the base, sometimes grown in flower-gardens.

Stems erect or decumbent, glaucescent: lvs. alternate or subopposite, linear- or oblong-lanceolate: fls. usually erect and solitary; sepals 3, ovate, caducous; petals 6, sometimes more, yellowish white or yellow or white, caducous or rarely persistent; stamens numerous; ovaries 6–20, distinct: fr. at maturity many carpels totally distinct or slightly joined, carpels moniliform.—About 60 species natives of the Pacific Coast according to Fedde (Engler's *Pflanzenreich*, hft. 40. IV:104), or 1 species according to Gray and a large number of American authors. *Platystemon* grows wild throughout Calif., except in the mountains, and is said to prefer a loose soil.

californicus, Benth. (*P. leiocarpus*, Fisch. & Mey.). **CREAM-CUPS**. Lvs. appearing opposite, sessile, ligulate-linear: petals light yellow, cream-color or white: carpels linear, moniliform, sometimes hispid. B.M. 3579. B.R. 1679. B. 2:65. Gn. 30, p. 313. G. 34:397.—*P. leiocarpus*, Fisch. & Mey., is the smooth-fruited form and is considered by some to be a distinct species, but is said by Gray in the *Synoptical Flora* to be "a mere state." F.C. 2:76. B.M. 3750.—*P. californicus* is frequently improperly called the California poppy but the true California poppy is *Eschscholtzia californica*.

F. TRACY HUBBARD.

PLATYSTÍGMA (Greek, *broad stigma*). *Papaveraceæ*. Low slender California annuals with pale yellow fls. less than 1 in. across. They are among the few plants of the poppy family with entire lvs. They are closely allied to *Platystemon*, but differ in having the filaments scarcely dilated, 3 stigmas instead of many, and the fr. a caps. which is 3-valved at the apex. Fls. commonly trimerous; stamens numerous, free; stigmas not confluent. Four species from Calif. and Ora. *P. lineare* is the only one with thick stigmas and also differs in its tufted habit, the others having leafy and branching sts. B.M. 3575, with pale yellow fls.; in B.R. 1954 it is shown with 3 white petals alternating with yellow ones. *Platystigmas* seem not to have been offered in Amer. By Fedde the species are referred to other genera.

PLATYTHÈCA (Greek, *broad anther-cells*). *Tremandraceæ*. Small shrub, somewhat heath-like, suitable for greenhouse culture.

Leaves whorled: fls. 5-merous, numerous, borne toward the end of the branches, light purple, about 1 in. across, center marked with a red star; stamens distinctly in 2 rows, anthers continuous on the same plane as the filament, with 4 parallel cells; disk inconspicuous: caps. loculicidally dehiscent, 4-valved. One species. Austral.—*Platytheca* belongs to a small beautiful and distinct family of Australian shrubs, composed of 3 genera, of which *Tetratea* is the dominant type. The *Tremandra* family resembles the *Polygala* family in the structure of the caps., but differs in the regularity and estivation of the fl.: it resembles the *Pittosporaceæ* in having a very small embryo immersed in copious albumen, and particularly the genus *Cheiranthra* in having anthers which open by a pore at the top. The three genera of *Tremandraceæ* are distinguished from one another by the anthers; *Tremandra* differs from the

other two in having the anthers jointed with the filaments; in *Platytheca* the anthers have 4 cells all in the same plane; in *Tetratea* the anthers are 2-celled or 4-celled, with 2 cells in front of the 2 others.

galioides, Steetz (*P. verticillata*, Baill.). Lvs. linear, $\frac{3}{4}$ in. long, about 10 in a whorl, hairy. Said to bloom in June. P.M. 13:171 (as *Tetratea verticillata*). G.C. III. 44:290.—This plant deserves to be better known. Cuttings of half-ripened wood root freely under a bell-glass in a shaded house at 60°. Cuttings rooted in February or March will make good plants in 5-inch pots in one year. In summer keep them plunged outside, but covered with shaded sash. By trimming frequently they will make well-shaped plants, needing no supports. Kept in a coolhouse (45°) during winter, they will be covered with bloom in March and April. The fls. last but a short time, but the plant is so free that it is always covered with the blue bloom.

H. D. DARLINGTON and WILHELM MILLER.

PLECTOCÔMIA (Greek, *plaited hair*; application obscure). *Palmaceæ*. Six species of East Indian climbing pinnate palms which fruit once and then die.

One of the most interesting species is *P. khasyana*, which is figured in B.M. 5105 under the erroneous title of *P. assamica*. This species has a slender st. 60–80 ft. long, and about as thick as a man's arm, being slightly thicker above than at the base. The lvs. attain 30 ft. and are pinnate only in the lower half, the rest of the lf. being a long whip-like extension of the rachis of the lf. A singular feature of this palm is the device by which it climbs. This consists of a series of compound spines shaped like a downward-pointing human hand, the back of the hand being yellow and the 5 or 6 fingers composed of brown spines. These organs are scattered all along the lower side of the flattened rachis. They hook on the branches of trees and thus enable the palm to climb for light. Probably all the species possess these flagelliform lvs. and remarkable genus. The whip-like lf.-tips may act as tendrils. The genus is little known to cultivators. It is allied to the rattans (*Calamus*), which also are climbers.

elongata, Mart. & Bl. Lvs. large; lfts. 1–1½ ft. x 2 in., sparsely white powdery beneath, with 3 very slender parallel nerves or costæ: fr. 1 in. diam., villous. Penang, Sumatra, Java.—Offered in 1890, but never much cult. in Amer. and probably not outside of botanic garden collections.

PLECTRÁNTHUS (Greek, *spur flower*; alluding to the swollen base of the corolla-tube). *Labiataæ*. Herbs and subshrubs, bearing rather small flowers ranging from blue and purple to lilac; sometimes planted for ornament in warm countries.

Inflorescence various; calyx 5-toothed, the teeth equal or variously 2-lipped; corolla-tube exserted, swollen behind at the base; limb 2-lipped; stamens 4, filaments toothless, free; nutlets ovoid or oblong, smooth or minutely punctulate.—About 120 species from the tropical and subtropical regions of Afr. and Asia to Japan, Austral., and Polynesia. The genus is closely allied to *Coleus*, being distinguished by having the stamens free instead of united at the base into a tube, which is distinct from the corolla. In other respects the genus has wide limits of variation. Sometimes called cocks-pur-flower. Prop. by cuttings which root easily.

fruticôsus, L'Hér. South African shrub, 3–4 ft. high: lvs. 4 in. or more long, petiolate, broadly ovate, doubly dentate: racemes laxly panicle; whorls about 3–6-fld.; fls. blue; pedicels 1½ in. long; corolla-tube spurred above the base; fruiting calyx declinate.—Said to be an elegant shrub; a specimen reported at Los Angeles is 4 ft. high and 6 ft. through.

P. albocarinatus, N. E. Br. A tall branched herb with broadly ovate lvs. 2–4 in. long: racemes crowded, spike-like; corolla white

and bluish. Trop. Afr.—*P. chiradzulensis*, Baker. About 3 ft. high, with slender branches; lvs. petioled, toothed not unlike those of the common nettle: fls. in terminal loose panicles 6 in. long, long-lipped and light blue; fls. in winter. Trop. Afr.—*P. ciliatus*, E. Mey. St. covered with purple hairs: lvs. broad, bright green above, purple-red beneath; fls. white with purple spots. S. Afr. Intro. into Italy.—Said to be a showy autumn- and winter-flowering plant with a compact habit.—*P. Coppinii*, Neck. A quick-growing species with root-tubers and also aerial ones produced in the axils of the branch-nodes. Trop. Afr. This species is cult. and the produce sold for food in the Soudan.—*P. crassus*, N. E. Br. A stout subshrub, covered with velvety hairs: lvs. ovate, 3-6 in. long, short-petioled, crenate, upper surface rich velvety green, under surface gray with prominent reticulate venation: fls. in stout erect terminal panicles 1 ft. or more long, purple-blue. Trop. Afr. B.M. 8030. Gn. 73, p. 629.—*P. Mahonii*, N. E. Br. Sts. 3 ft. high: lvs. ovate, 3-4 in. long, petioled, the lower cuneate, the upper cordate at the base, toothed; racemes 3-8 in. long, loosely many-fl.; fls. rather small, violet-blue. Trop. Afr. B.M. 7818.—*P. saccatus*, Benth. Subshrubby and rather succulent, with horizontally spreading branches about 1 ft. long; lvs. 2-3 in. long, ovate, coarsely toothed; racemes erect, simple, lax-fl.; corolla large, pale blue. Natal. B.M. 7841. Intro. into English botanic gardens and said to be a very ornamental species with probably the largest fls. of the genus.

F. TRACY HUBBARD.

PLECTRŌNIA (Greek, *cockspur*; referring to the spines). *Rubiaceæ*. Woody plants sometimes cultivated in warm regions for the ornamental flowers. They are more or less spiny and have somewhat funnel-shaped 5-parted fls., with reflexed segms. valvate in the bud, and a hairy or naked throat; calyx obovate or oblong; stamens 5, in the throat; style short; stigma subcapitate, of 2 approximate lamellæ: berry obovate-oblong, compressed, didymous, 2-stoned; stones indehiscent, 1-seeded.—About 150 species of shrubs or small trees, found in the Old World, mostly in the tropics.

spinosa, Klotzsch. Very spiny S. African shrub, 5-8 ft. high: lvs. fasciculate, oval or obovate, obtuse, entire, 1-1½ in. long; racemes or panicles shorter than the lvs.; peduncles axillary, 5-12-fl.; corolla-tube shorter than the limb; throat naked.—Intro. into S. Calif.

PLEIOCÁRPA (Greek, *many fruits*). *Apocynaceæ*. Glabrous shrubs or small trees, grown under glass for the bloom: lvs. opposite or ternate, leathery: fls. in sessile axillary and often opposite clusters, very rarely in compact panicles or false umbels; calyx small, glandular; sepals 5, almost or quite free, obtuse or acute; corolla salver-shaped, tube slightly widened below the mouth, lobes 5, overlapping to the left; carpels 2-5, distinct: fr. fleshy, berry-like mericarps, leathery when dry, 1- or 2- (rarely 3-) seeded. About 10 species, Trop. Afr. *P. mitica*, Benth. Shrub 5 ft. high: lvs. opposite, elliptic or oblong, 3-6 in. long, thinly coriaceous: fls. in dense axillary, globose clusters; sepals ovate; corolla pure white, tube cylindric, ¾ to ¾ in. long, lobes ovate or oblong. B.M. 8343. G.C.III. 49:242. Cult. in botanic gardens abroad. The plant likes heat and moisture and about the same treatment as given ixoras.

PLEIOGÝNIUM (Greek, *many and wives*, meaning not clear). *Anacardiaceæ*. Tree recently intro. by the U. S. Department of Agriculture for experimental purposes. Lvs. odd-pinnate; lfts. ovate, wedge-shaped at base: fls. dioecious, in numerous axillary racemes, those with male fls. as long as the lvs., those with female fls. shorter; petals obovate; stamens 10; ovary in female fls. 5-10-12-celled: drupe somewhat compressed, broad-top-shaped. One species, Queensland, Austral. P. *Solandri*, Engl. Tree, 40-60 ft. high: trunk occasionally very thick, 2-3 ft. diam.: lfts. 7-9, obliquely ovate or oblong, obtuse, 2-3 in. long, entire: fls. sessile, densely clustered in short axillary racemes, rarely panicles; petals 5, spreading. Queensland.—The timber when first cut is soft, but afterward becomes hard and tough. Possibly may be used as stock for less hardy anacardiaceous fr.-bearing trees. Its adaptabilities in N. Amer. are not yet known.

PLEIŌNE (from Greek mythology: *Pleione*, mother of the Pleiades). *Orchidaceæ*. A small group of orchids related to *Cœlogyne*, and requiring similar treatment.

Pseudobulbs soon dying: lvs. thin, deciduous, falling usually after the pseudobulbs are matured: fls. large, brightly colored, one or two borne on short scapes produced from base of pseudobulbs.—About 13 species (Pfitzer & Kränzlin, Engler's Pflanzenreich, hft. 1907), of the mountains of India, extending to elevations where snow and frost are not uncommon. Few are cult. in Amer.

maculata, Lindl. Pseudobulbs round, flattened, depressed at the top, forming a fleshy ridge around the summit: lvs. lanceolate, from inflated sheaths: fls. preceding the lvs., on short peduncles; sepals and petals lanceolate, spreading, white; labellum funnel-shaped, with 5-7 fringed lamellæ extending the entire length of the labellum side lobes streaked with purple, middle lobe ovate, wavy, white, spotted with purple and yellow.

The lvs. fall in Sept.; fls. in Nov. B.M. 4691. F.S. 14:1470. F. 1851:97 (all as *Cœlogyne maculata*). Var. *Bermánica* was once offered by Wm. Mathews.

3067. *Pleione præcox*. (×½)

præcox, D. Don (P. *Wallichiana*, Lindl. & Paxt.). Fig. 3067. Pseudobulbs flask-shaped, depressed, dull green, warted and covered with a network of the old split sheaths: lvs. broadly lanceolate, plicate: fls. large, on short peduncles; sepals long, lanceolate, spreading, pink; petals similar but narrower; labellum trumpet-shaped, indistinctly lobed, pink, white and yellow in the throat; disk with longitudinal fringed

lamellæ, margin dentate-fimbriate. Oct., Nov. B.M. 4496. B.R. 26:24. P.M. 6:25 (all as *Cœlogyne Wallichiana*). G. 32:743. J. I. 2:153. O. 1914:72.

lagenaria, Lindl. & Paxt. Pseudobulbs clustered and depressed, as in the other species, dull green, mottled with brown: fls. about 4 in. across, rose-lilac; sepals and petals narrowly lanceolate; labellum convolute, crisp on the margin, pale lilac, blotched with yellow and deep crimson in the throat and having several yellow crests. Aug.-Nov. Himalaya Mts. B.M. 5370. F.S. 23:2386. I.H. 14:510 (all as *Cœlogyne lagenaria*). Gn. 51, p. 64. O. 1914, p. 77.

Reichenbachiana, T. Moore. Pseudobulbs 5-8-grooved, flask-shaped but suddenly contracted at the top: scape 1-2 in. long, closely sheathed; sepals and petals linear-oblong, pale purple to white; labellum nearly white, middle lobe white with few pale purple spots, with 3 crests; margin ciliate-toothed. Autumn. Rangoon. B.M. 5753.

P. Hookeriana, T. Moore. Pseudobulbs seldom over 1 in. high: lvs. small, produced with the fls.: fls. 2-2½ in. across, rose-purple; lip lighter; throat pale yellow. Sikkim. O. 1914, p. 75.—*P. himilalis*, D. Don. Pseudobulbs 1-lvd.: lvs. up to 8 in. long, 1½ in. wide: scape 1- or rarely 2-fl.; fls. nodding; sepals lanceolate, somewhat acute, white, 1½-2 in. long; petals similar, white, obovate from a cuneate base; lip emarginate, the disk yellow, brown-spotted. Trop. Himalayas. J.F. 2:158. B.M. 5674.—*P. pogonioides*, Rolfe. Fls. terminal, showy, rosy red with a whitish disk; sepals and petals somewhat connivent, oblong-lanceolate, about 1½ in. long; lip large, convolute around the column. China. B.M. 8588.—*P. Schilleriana*, Pfitz. & Kränzlin. Pseudobulbs 2-lvd.: fls. yellow, with

lip spotted purple or orange-red; lip deeply 3-lobed. Moulmein. O. 1914, p. 78.—*P. yunnanensis*, Rolfe. Fls. rose or purple; sepals and petals similar, $1\frac{1}{2}$ in. long, about $\frac{1}{2}$ in. broad, oblong-obovate; lip broadly cuneate, 3-lobed, about $1\frac{1}{4}$ in. long and broad. Yunnan. B.M. 8106. G.C. III. 41:152; 59:161. G.M. 49:781. J.H. III. 52:251. O. 1914, p. 79.

GEORGE V. NASH.†

PLEIOSPÉRMUM (from the Greek for *many* and *seed*). *Rutaceae*, tribe *Citræe*. Small trees distantly related to *Citrus*, but having fruits filled with mucilaginous pulp. *Limonia* § *Pleiospermium*, Engler, 1896.

Leaves trifoliate, bifoliate, or unifoliate; spines straight, singly or in pairs in the axils of the lvs.; fls. in terminal panicles or axillary clusters; ovary 5-celled with 2 ovules in each cell.—Two species are known, ranging from India and Ceylon to Java. Both species of *Pleiospermium* are small trees, and both should be tested as stocks upon which to graft the common citrus frs. So far, attempts to intro. living seeds of *P. alatum* from India to this country have failed, possibly because of the large size and soft texture of the seeds.

alatum, Swingle (*Limonia alata*, Wight & Arn.). **TUMPAT-KURUNDU**. Small tree, common in S. India and Ceylon, especially in the dry regions: small branches, spineless or with spines 1 in. long; lvs. trifoliate; flts. obovate, petioles winged; fl.-buds downy; fls. 4-5-parted, short-pedicelled in terminal or axillary panicles; fr. globose, 5-celled with 2 rather large seeds or rudiments of seeds in each cell, imbedded in a mucilaginous pulp. Ill. Wight, Ill. Ind. Bot., pl. 41.—The wood is hard and close-grained, much like that of *Chalcas exotica*.

dùbium, Swingle (*Limonia diphyllo*, Houttuyn(?). *L. dubia*, Blume. *Paramignya Blumei*, Hassk.). **KIDJEROEKAN**. A small tree, native to Java, 9-12 ft. in height, branching out about 4-5 ft. from the ground, and having numerous suckers at the base; branches spiny or spineless; lvs. unifoliate, bifoliate, or trifoliate; petioles slightly winged; fls. in short axillary clusters of 5-15; ovary pubescent; frs. the size of a pigeon's egg, filled with unpleasantly aromatic resin secreted by pulp vesicles 3-4 mm. long. See Journ. Wash. Acad. Sci. 6, No. 13. WALTER T. SWINGLE.

PLEOCNÈMIA: *Dryopteris*.

PLERÒMA: *Tibouchina*.

PLEUROSPÉRMUM (Greek *ribs* and *seed*, referring to the strong ridges on the fr.). *Umbelliferae*. Biennial or perennial herbs, tall or low, and glabrous, hardy and somewhat ornamental: lvs. pinnate or compound-pinnate, segms. ovate, dentate, incised, or divided into narrow segms.; umbel composite, many-rayed; involucre and involucral bracts many, often membranaceous or lf.-like; fls. white or dark purple; calyx-teeth small, ovate, or rarely obsolete; petals large for the family, obovate or cuneate; fr. oblong, ovoid, or subglobose.—About 45 species, a few in Eu., mostly in Asia, sometimes planted for ornament.

austriacum, Hoffm. Perennial, 2-3 ft. high; st. upright, striate; lvs. dark green, rather thick, shiny, 2-3 times pinnatifid, the lower petioled, triangular in outline, the upper more or less sessile; umbel flat, up to 40 rays; calyx weakly toothed, the teeth short and obtuse; petals white, clawed, broad ovate, acutish. Eu.

PLEUROTHÁLLIS (Greek, *lateral branch*; referring to the inflorescence, which arises from the axil of the leaf). *Orchidaceae*. Epiphytic orchids which on account of their small inconspicuous flowers are of no particular horticultural value, and not generally cultivated, although interesting.

Stems clustered on the rhizome, sheathed with scales below and bearing a single lf. at the summit; fls. in a nodding raceme from the axil of the lf.; sepals free or

the lateral ones united at the base; petals smaller; labellum free, similar to the petals or 3-lobed; column short, without lateral branches.—One of the largest of the genera of orchids containing about 400 species, dispersed in the region extending from Brazil and Bolivia to Mex. and the W. Indies.

Roëzii, Reichb. f. Lvs. oblong-lanceolate, 4-10 in. long; fl.-st. often a little longer than the lvs.; fls. purple-brown, in a 1-sided raceme. Columbia. Gt. 50, p. 272.

ornata, Reichb. f. A very small caespitose plant with lvs. scarcely 1 in. long; fls. opening successively on erect, zigzag racemes a few inches long, inconspicuous, yellow with brown spots. B.M. 7094.—The plant is easily distinguished by the sepals, which are fringed with silvery pendulous hairs.

P. apiculata, Lindl. Lvs. 1-2 in. long, linear-lanceolate; racemes 3-5-fld., about as long as lvs.; fls. pale yellow, about $\frac{1}{2}$ in. long. Venezuela.—*P. attenuata*, Rolfe. Lvs. elliptic, 1-1 $\frac{1}{4}$ in. long; scapes slender, 2-4-fld.; fls. about $\frac{3}{4}$ in. long; sepals and petals light green marked with purple; lip greenish white.—*P. barbosana*, De Wild. Lvs. small, oblong-lanceolate; fls. small, yellow, rather nodding. Brazil.—*P. Birchenallii*, Rolfe. Fls. 3-7 in a raceme; sepals dull reddish purple, the dorsal green-margined at base, lanceolate, long-acuminate, nearly 2 in. long; petals long-acuminate, about $1\frac{1}{4}$ in. long, light green striped brown at base; lip 3-lobed, less than $\frac{1}{2}$ in. long, the erect side lobes greenish white, the front lobe dull reddish purple. Colombia. G.C. III. 45:391.—*P. Cogniauxiana*, Schlecht. Fls. densely hairy on outside, pale, densely covered with purple markings. Costa Rica.—*P. crinita*, Hort. Very small; lvs. orbicular; inf. bearing 4 fls., each about $\frac{1}{2}$ in. long, covered outside with long whitish hairs; dorsal sepal light green, with pale brown dots; lateral sepals united, red-purple. Brazil.—*P. cuneifolia*, Cogn. Lvs. very fleshy, lanceolate; fls. $1\frac{1}{2}$ in. long; lower half of sepals thin, pale yellow with red spots, upper half very fleshy, pale reddish brown. Brazil.—*P. dubia*, A. Rich. Small, creeping; fls. yellow, with shining orange-yellow lip. Mex.—*P. pectinata*, Lindl. Raceme distichous; fls. sea-green, with a few deep purple spots on base of lip; sepals pubescent, elongated, the dorsal linear; petals linear-lanceolate; lip clawed, oblong, toothed at base. Brazil. G.W. 14, p. 523; 15, p. 680.—*P. repens*, Ames. Lvs. $1\frac{1}{2}$ -2 in. long, elliptic-oblong; peduncles 1-fld.; fls. 3-3 $\frac{1}{2}$ in. long, reddish brown. S. Brazil.—*P. rubens*, Lindl. Raceme very long; sepals lanceolate, acuminate; petals obtuse; lip obovate, repand, obtuse. Brazil. G.W. 13, p. 367.—*P. subulifolia*, Kränzl. Lvs. nearly 2 in. long, subulate; racemes slightly longer than lvs., 5- or more-fld.; fls. about $\frac{1}{2}$ in. long, yellow, with purple lines. Brazil.—*P. venosa*, Rolfe. Lvs. $5\frac{1}{2}$ -8 in. long, lanceolate-oblong; racemes many-fld., 4-6 in. long; fls. very small, greenish. Trop. Amer.

GEORGE V. NASH.†

PLÓCAMA (Greek, *bent hairs*, alluding to the pendulous branches). *Rubiaceae*. Erect branched shrubs, usually fetid, to be grown under glass for the bloom or planted out far S.; branches very slender, pendulous; lvs. opposite or verticillate in 4's, linear-elongate, filiform, acute, flaccid; stipules connate into a short scarious sheath, persistent; fls. minute, axillary or terminal; calyx-tube globose, 5-lobed, persistent; corolla funnel-form-campanulate, short-tubed, pilose-throated, limb 5-7-lobed, lobes oblong-lanceolate with the tip bent and callous, valvate; stamens 5-7; ovary 2-3-celled; fr. a small globose, white, succulent berry. One species, Canary Isls. *P. péndula*, Ait., the only species, grows about 2 ft. high, has white fls. and linear-oblong filiform lvs. Intro. in S. Calif. and also cult. in greenhouses abroad.

PLUKENÉTIA (from Leonh. Plukenet, an English botanist of the 17th century). *Euphorbiaceae*. Woody climbers, sometimes cult. in the tropics for the fr.: lvs. alternate, simple, often cordate, 3-5-nerved; fls. small, in lateral clusters, apetalous; calyx valvate; stamens 8-30; styles united to the apex into a swollen column; ovules 1 in each cell of the ovary. About 12 species in the tropics of both hemispheres. Related to *Dalechampia* and *Tragia*. The 4-lobed fr. of the following species is edible and has been utilized for hog-feed, for which they are frequently planted in their native land. *P. volubilis*, Linn. Style-column long and slender; lvs. cordate, somewhat pointed, repand or serrate on margin. W. Indies. *P. corniculata*, Smith. Style-column ovoid or hemispherical. Java; lvs. said to be aromatic and used as a pot-herb. J. B. S. NORTON.

PLUM. The tree and fruit of many species of *Prunus*. A few kinds are grown for the ornamental flowers and others for colored or variegated foliage. Prunes are cured dried plums.

It is probably more difficult to give specific practical advice for the management of the plum than for any other common fruit, for the reason that it represents

3068. Plum.—Peter Yellow Gage. ($\times \frac{1}{2}$)

several distinct species which are not equally adapted to all parts of the country, and the same remarks will not apply to them all. There is no country in which the domesticated plum flora is so complex as in North America, for not only are the specific types of Europe and of Japan grown, but also species that are peculiar to this continent. In the northeastern states and on the Pacific slope the European or domestica types are the leading plums. In these same areas and also in the South and in parts of the mid-continental region, the Japanese plums also are now popular. In the cold North, in the great interior basin, and also in many parts of the South, various native types now constitute the leading cultivated plums. These native plums are developed from wild species of the country, and they are unknown in cultivation (except in botanical or amateur collections) in any other part of the world. These have been developed chiefly within fifty and sixty years, although a few varieties are older than this. For a history of this evolution, see Bailey, "Sketch of the Evolution of our Native Fruits," also, as well as for culture and varieties of plums in general, Waugh, "Plums and Plum-Culture," and Hedrick, "The Plums of New York." See *Prunus*.

The plums cultivated in North America may be arranged in the following groups:

1. Domestica or European types, *Prunus domestica*. Native to western Asia, comprising the common or old-time plums, such as Green Gage, Lombard, Bradshaw, Yellow Egg, and the like. They are the leading plums from Lake Michigan eastward and north of the Ohio, and on the Pacific slope. Figs. 3068, 3069 are of this species. The Damsons (Fig. 3070) are small-fruited forms of this general species-type. Of late years, hardy races of *Prunus domestica* have been introduced from Russia. These have value for the colder parts of the plum-growing regions. Figs. 3071, 3072, show representative forms of the Russian type.

2. The Myrobalan or cherry-plum type, *Prunus cerasifera*. Native to southeastern Europe or southwestern Asia. The seedlings are much used for stocks upon which to bud plums; the species is also the parent of a few named varieties, as Golden Cherry; and DeCaradeuc and Marianna are either offshoots of it or hybrids between it and one of the native plums, probably hybrids.

3. Japanese types, *Prunus salicina* (*P. triflora*). Evidently native to China. The type seems to be gener-

ally adapted to the United States, and is of great value to both the South and North. This species first appeared in this country in 1870, having been introduced into California from Japan. For historical sketch, see Bulletin No. 62, Cornell Experiment Station (1894); also Bulletin No. 106 (1896); Hedrick, "The Plums of New York." Fig. 3073 shows one of these plums; also Fig. 3074, as to tree forms, which are very variable in the different pomological varieties.

4. The apricot or Simon plum, *Prunus Simonii*. Native to China. Widely disseminated in this country, but little grown except in parts of California. Introduced about 1881.

5. The americana types, *Prunus americana*, *P. nigra* (Figs. 3075, 3076), and *P. mexicana*. The common wild plum of the North, and extending westward to the Rocky Mountains and southward to the Gulf and Texas. Admirably adapted to climates too severe for the domestica plums, as the Plains and the upper Mississippi Valley.

6. The Wild Goose and Chickasaw types, *Prunus hortulana*, *P. angustifolia*, *P. Munsoniana* (Figs. 3076, 3077). A variable type of plums, comprising such kinds as Wild Goose, Wayland, Moreman, Miner, Golden Beauty, Newman, Caddo Chief, Lone Star, and many others. The species involved in this group are not yet clearly defined botanically, and what part the hybrid and intergradient forms play in the evolution of cultivated varieties is yet largely to be determined. In adaptability they range from Michigan to Texas, eastward and westward, but are essentially fruits of the great interior basin.

7. The Beach plum, *Prunus maritima*. Native to the coast from New Brunswick to Virginia. In cultivation, represented by the unimportant Bassett's American; also as an ornamental plant.

8. The Pacific Coast native plum, *Prunus subcordata*, wild in California and Oregon. Sparingly brought into cultivation, chiefly in the form known as the Sisson plum.

The welding of these many stocks will undoubtedly produce a wide range of fruits in the future, of which we yet see only the first promise. The experiments of Hansen in South Dakota in hybridizing *P. Simonii* and

3069. Plum.—Fellenberg or Italian prune. ($\times \frac{1}{2}$)

P. americana, *P. salicina* and *P. americana*, *P. Besseyi* with plums, and others for a marginal climate, as well as the experiences of other workers in combining many of the species, all point to a wealth of plums for a continental area.

The plum of history is *Prunus domestica*. It is to this species that general pomological literature applies. It gives us the prunes (see *Prune*). These plums may

be thrown into five general groups, although any classification is arbitrary at certain points:

1. Prunes, characterized by sweet firm flesh, and capable of making a commercial dried product. They may be of any color, although blue-purple prunes are best known. Some of the prunes are grown in the East as ordinary market plums, being sold in the fresh state. Almost any plum can be made into dried prunes, but the varieties used commercially for this purpose constitute a more or less distinct class of sweet and thick-fleshed kinds (see definition, page 2719). In the East, prune is nothing more than a varietal name.

2. Damsons, comprising very small firm plums of various colors, usually borne in clusters, the leaves mostly small. The run-wild plums of old roadsides and farmyards are mostly of the general damson type (Fig. 3070).

3. The green gages, comprising various small green or yellow-green plums, of spherical form and mostly of high quality. Reine Claude is the commonest

continuously hot for other plums or where the fruit-rot fungus is too prevalent.

The domestica varieties are mostly fertile with themselves, but the natives usually bear best in mixed planting so that pollination is assured. See *Pollination*. The Japanese varieties also usually profit by mixed planting. How far failure to set fruit is due in general to lack of pollination and how far to other causes, is yet largely to be worked out.

Plum-growing.

The plum thrives on a variety of soils. The domesticas commonly do best when planted in clay loam. They usually thrive well on lands which are suited to pears, or on the heavier lands to which apples are adapted. Yet many varieties grow well on lands that are comparatively light or even almost sandy, with good care. The americanas thrive best in a rather moist soil, and mulching is often very favorable to the size and quality of the fruit.

The stocks upon which plums are grown are various. By far the greater number of the trees in the North are now grown on Myrobalan, which is a species of rather slow-growing plum (*Prunus cerasifera*), native to southeastern Europe and southwestern Asia. This is the stock sometimes recommended in the older fruit-books for the making of dwarf trees; but unless the top is kept well headed in, the trees generally make normal growth upon it. Trees grown on this root are usually larger and finer at one or two years of age than those grown on other plum stocks, and the probability is that they are nearly as useful from the grower's standpoint as any other. However, there are some varieties that overgrow the Myrobalan, and the stock is likely to sprout from the ground and thereby cause trouble. The Myrobalan is variable from seed, and this fact may account for some of the unsatisfactory results now and then reported.

St. Julien is perhaps a better stock, but is more expensive to import and less readily budded. The Myrobalan and St. Julien stocks are imported.

Probably the best stock for domesticas, from the standpoint of the grower, is the domestica itself, but seeds of it are more difficult to secure, the stock is more variable and it is more likely to be injured in the nursery row by leaf-fungi; therefore, as a matter of practice, the Myrobalan has very generally supplanted it. In the middle and southern states the peach is largely used as a stock upon which to grow plums, and it seems to be gaining favor in the North. It is undoubtedly a very excellent stock for sandy lands, and, in fact, is probably better for such lands than the Myrobalan itself. Some varieties—of which Lombard and French Damson are examples—do not take well on the peach. The Japanese plums are commonly worked on the peach. The Marianna stock, which is much recommended in the South, has not found favor in the North. Some varieties of plums are such slow and crooked growers in the nursery that it is advisable to top-graft or bud them on some strong and straight stock. The Lombard is no doubt the most adaptable stock for this purpose now grown by nurserymen. The old Union Purple is one of the best stocks, but is not much grown at present. Reine Claude, German Prune, and Copper are probably best when top-worked on some strong stock. For many native varieties, seedlings of vigorous natives, as of Golden Beauty and Wayland, make excellent stocks. Americanas should be worked on their own seedlings, at least in the North. In the South they are often budded on Marianna. The whole subject of plum stocks needs experimental study.

3070. Damson plum. ($\times \frac{3}{4}$)

representative of this group in the East. The name green gage often stands for a group rather than for a variety.

4. Large yellow plums, such as Coe Golden Drop, Washington, and the like.

5. Large colored plums, including the various red, blue, and purple varieties, like the blue prunes, Lombard, Bradshaw, Quackenboss, and the like.

The Japanese plums (*Prunus salicina*) differ from the domesticas in having longer thinner smooth and mostly shining leaves, smooth twigs, a greater tendency to the production of lateral fruit-buds on the annual growth, and mostly rounder or shorter fruits with colors running more to cherry-reds and light yellows. Most of the varieties are as hardy as the domestica series. The Japanese varieties are important because they add variety to the list, and especially because they are rich in very early kinds, and the fruit is usually so firm that it carries well; aside from this, the trees are vigorous and very productive, and the species is less liable to injuries from black-knot and curculio than the domesticas.

The native plums, chiefly offspring of *Prunus americana*, *P. nigra*, *P. angustifolia*, *P. Munsoniana*, and *P. hortulana* represent a wide range of varieties. Those from *Prunus americana* and *P. nigra* parentage are very hardy and are adapted to regions in which the domestica and Japanese types are tender, as in northern New England, parts of Canada, and the northern plains states. Those partaking strongly of *P. angustifolia* parentage, and the greater part of the hortulanas, thrive well in the South, where the climate is too con-

XC. Bavay or Reine Claude (Reine Claude de Bavay), one of the Green Gage plums of American orchards.

Plum trees are usually planted when two years old from the bud, although some of the strong-growing kinds may be planted at a year old with the very best results. As a rule, all plum trees are planted about as far apart as are peaches, that is, from 15 to 20 feet each way. Many growers prefer to plant them closer one way than the other and eventually to stop cultivation in one direction. If this system is used, they

3071. Early Red, one of the Russian plums. ($\times \frac{3}{8}$)

may be placed 18 or 20 feet apart one way, and 8 to 12 feet the other way. When planted, the trees are pruned in essentially the same way as apple trees. It is usually advisable to start tops as low as possible and yet allow of the working of the curculio-catcher or other tools below them. This means that the limbs should start from 3 to 4 feet above the ground. With the modern implements and methods of tillage, there is little inconvenience in working the land if tops are started as low as this. The subsequent pruning of the plum tree has no special difficulties. About four or five main limbs are allowed to form the framework of the top, and in most varieties, especially those which are not very tall growers, the central trunk or leader may be allowed to remain. The fruit of the domesticas is borne mostly on spurs, as shown in Fig. 3078. These spurs, therefore, should not be removed unless it is desired to thin the fruit. In the americanas and the Japanese varieties, the fruit is borne both on spurs and on the annual axial growth.

Insects and diseases.—The black-knot is one of the most serious plum diseases. It is best kept in check by systematically cutting it out (several inches below the swelling) and burning it. The grower should go over his orchard for it in the summer and again as soon as the leaves fall. If trees are thoroughly sprayed every year with self-boiled lime-sulfur or bordeaux mixture for the leaf-blight fungus, the black-knot will make comparatively little headway in the orchard.

The blight, which causes the leaves to fall in August or September, is a damaging disease; but it can readily be kept in check by thorough spraying with self-boiled lime-sulfur or bordeaux mixture two or three times during the summer. The mixture for spraying plums should be weaker than for apples, particularly for the Japanese varieties.

The fruit-rot is the work of a fungus. Many times the dead and dried fruit may be seen hanging on the tree all winter, as shown in Fig. 3079; and in such cases it is very likely that the fruit-spur may be killed, as the upper one in the picture has been. In handling this disease, the first consideration is the fact that some varieties are much more susceptible to it than others. The Lombard is one of the worst. Again, if the fruit grows in dense clusters, the disease is more likely to be severe. The thinning of the fruit, therefore, is one of the best preventives of the spread of the disease, and at the same time, also, one of the most efficient means of increasing the size, quality, and salableness of the product. Thorough spraying with self-boiled lime-sulfur

is a specific for the trouble and helpful in related troubles or diseases.

The curculio, which causes wormy fruit, can be held in check by the process described under Peach. Formerly, jarring the beetles on sheets or curculio-catchers (a wheelbarrow-like device with a large cloth hopper) was the prevailing practice with those who gave extra care to their fruit, and this method is still recommendable to amateurs and small plantations; but with the modern good tillage and the practice of keeping all parts of the plantation and the hedge-rows clean, and with the introduction of more effective spraying, the curculio is found to do much less damage and usually to be held sufficiently in check. Practising open pruning to let in the sun, and raking the dropped fruit out into the sun will also check the breeding. How far spraying with arsenicals will control the curculio on plums is not yet well understood, but growers usually feel that it is a distinct aid. To the bordeaux mixture or to self-boiled lime-sulfur, two and one-half pounds of arsenate of lead may be used to the fifty gallons, in one spraying soon after the petals drop, and another a week or ten days later.

L. H. B.

Native American plums.

Approximately 300 varieties of plums, derived chiefly from six native types, have been named, described, and introduced by American nurserymen and have found their way into American orchards and American pomological literature. The major part of this interesting development came in response to the urgent demand, most manifest in the years from 1870 to 1900, for the discovery of new types of garden fruits suited to the peculiar conditions of the middle western prairie states. Outside this area, the native American plums made much less impression, and while they have been widely tried, they have been generally discarded. Even in the area to which they are native and in which the need for them is greatest, they do not now play an exclusive rôle. A large part of the named varieties introduced by the nurserymen have already been lost to American horticulture. A creditable minority of these varieties, however, have qualities of absolute and considerable merit, and may be looked on as permanent additions to our pomological wealth. The native varieties are still propagated and planted by thousands annually, both for home use and for market. For certain culinary purposes, many of the natives are superior; and in many places, particularly in states of middle latitude, they are the most profitable market plums grown.

The americana plums are especially qualified to withstand the severity of northern winters. They are superlatively hardy. They are practically the only plums

3072. Voronesh Yellow, a Russian plum of somewhat recent introduction. ($\times \frac{3}{8}$)

grown in the cold northwestern states (except the comparatively unimportant *nigras* and the *Miners*) and their usefulness in northern New England and middle Canada is limited only by the extent to which they are known. Their cultivation has been developed to a special degree in Iowa, Wisconsin, Minnesota, and adjacent states. For this region they must be propagated always on *americana* stock. This stock has other advantages besides its hardiness, and it is coming into extensive use for all sorts of plums in the Northwest. The sand cherry is sometimes used as a stock, but has not yet passed the experimental stage. It dwarfs *americana* plums worked on it. It is perfectly hardy.

The *americana* plums are wayward and awkward growers. With many varieties it is impossible to make a comely orchard tree. They do not appear to take kindly to pruning; and the usual method has been to let them very much alone. Careful pruning during the first few years, directed with a view to forming an open top on comparatively few supporting main branches, will do something toward shaping the trees; but with our present knowledge, no extensive pruning can be recommended for mature trees. The method of heading-in, as often practised with the domestic plums, is especially unadapted to the *americanas*.

The *americana* plums are early and very prolific bearers. Overbearing is a habit and a serious fault with most varieties. Extensive thinning of the fruit is indispensable. The trees are sometimes severely attacked by shot-hole fungus, and thorough spraying with bordeaux mixture or lime-sulfur is necessary. The fruit-rot (*sclerotinia*) attacks all the native plums more or less, and must be controlled by the usual remedies. See *Diseases and Insects*, Vol. II.

The *nigra* group has two or three important varieties of superior hardiness, as *Cheney* and *Aitkin*. In general, they bloom earlier and fruit less heavily than the *americanas*. Their habits and culture are the same.

The *Miner*-like varieties are hardly to be distinguished from the *americanas* in any way. They have practically the same geographical range, and may be given the same treatment in the orchard.

The *hortulana* group includes several varieties of great value, especially for the South. Of these, *Wayland*, *Golden Beauty*, *Moreman*, *Benson*, and *Kanawha* may be mentioned. They are not to be recommended generally for localities north of Massachusetts and Nebraska, their northern limit being determined less by their non-hardiness than by the very late ripening. This habit of late ripening, combined with very late blooming, makes them desirable for late marketing, particularly in southern markets. They are very prolific and constant bearers. The trees are free-growing, usually of rather spreading habit, and will bear heading-back better than the *americanas*. The pruning-knife, if used in season and with good judgment, will assist in making comparatively open-headed trees of these varieties.

The *Wild Goose* group (*P. Munsoniana*) includes varieties like *Wild Goose*, *Milton*, *Wooton*, and *Whitaker*, specially adapted to the latitude of Maryland, Kentucky, and Kansas. They succeed only less well southward; but are not generally valuable to the north of this line. For the section named, the varieties of this class have unquestionably been the most profitable

plums grown up to the present time. They are propagated chiefly on peach, *Marianna*, and *Myrobalan*, but succeed even better on *americana* stocks. These stocks are all fairly satisfactory, though not equally good for all varieties; but, when peach stocks are used, the union should be made by whip-grafting on the peach root. Otherwise the peach stock comes above the ground and is a prey to the peach borer. The trees are mostly rapid willowy rather zigzag growers; and are amenable to the pruning-knife in about the same degree as the *Wayland*-like varieties already mentioned. *Whitaker* makes an open-headed tree without much trouble. So does *Sophie*. *Wild Goose* is more inclined to be thick and thorny in the top, but may be thinned carefully to make an accessible head. *Milton* is much like *Wild Goose*. *Wooton* makes a fine vase-form top, which, with a little timely pruning, is almost ideal. *Wilder*, *James Vick*, and some others, are prone to make thick bushy thorny tops, and are hard to manage. These varieties are all considerably subject to shot-hole fungus, which often strips them of their foliage in mid-summer. They are mostly thin-skinned and liable to crack at ripening times, especially if the weather is wet. They should be picked rather green for shipment, the point to be observed being that they have attained their full size, rather than that they are dead ripe.

The *Chickasaw* varieties (*P. angustifolia*) are effective pollinizers for the *Wild Goose* and *Japanese* varieties blooming at same time; but very few of them have sufficient value in themselves to make them profitable orchard trees. A few varieties, like *Munson* and *McCartney*, are still planted for their own fruit; but in general they have been displaced by other types of plums. The trees are mostly bushy, thorny and thick-topped, sometimes so thick and thorny that the black-birds can hardly get in to steal the fruit. It is difficult

to prune them enough to make really satisfactory trees. The *Chickasaw* plums are specially adapted to the southern states, though *Pottawatamie* (probably a form of *Prunus Munsoniana*) succeeds as far north as southern Iowa and central Vermont. They propagate readily on any kind of stocks, but are very much given to suckering wherever they make roots of their own.

Other types of native plums, such as the *Sand plum*, the *Beach plum*, the *Pacific plum*, and the like, are not sufficiently

numerous in cultivation for their treatment to have been determined.

Hybrid plums of various strains have been introduced in considerable numbers. Most of these hybrid varieties resemble rather strongly one or the other of their parent species; and the best that can be said regarding their culture at this early day is that they may be safely treated like the varieties which they most closely resemble. *Wickson*, *President*, and perhaps *Climax*, with some others, resemble the *Simon* plum, and ought to have much the same treatment, that is, practically the same treatment as the *Japanese* varieties. *Gonzales*, *Excelsior*, *Golden*, and *Juicy*, on the other hand, resemble the *Wild Goose* type, and may have the same general treatment as *Wild Goose*. Some of these hybrid varieties, especially crosses of *Wild Goose* and *Chickasaw* types with the *Japanese* plums, are making some stand commercially, especially in the South, West, and in the Rocky Mountain States.

3073. The Japanese type (*Prunus salicina*).—*Maru*; once grown. (×½)

All the native plums, with wholly negligible exceptions, require cross-pollination. For the most part, however, they are fully inter-fertile, so that one given variety will pollinate any other variety, providing the two bloom at the same time. Simultaneous blooming is of chief importance in adjusting varieties to one another for cross-pollination. To determine which varieties bloom together, careful observations should be made in

fermentation around the pit in the process of drying, which prevents their being successfully dried without its removal; these are known as "plums." The prune varieties are, however, much richer in sugar which determines their adaptability to drying whole. As California has to find distant markets for most of its immense fruit crops, by far the greater portion of the plum areas are devoted to the production of prunes. The total amounts of plums produced in 1914 are as follows: Dried prunes, 51,000 tons; canned plums,

3074. Forms of tree of Japanese plums, at early bearing age.—Left to right: Abundance, G. sorgeson, Burbank, Wickson. The Wickson is probably a hybrid with *P. Simoni*.

the orchard and recorded, or recourse must be had to the published tables. Pollination is effected chiefly, if not exclusively, by the bees, so that their presence should be encouraged.

Most of the native plums make comparatively small trees, so that they may be set somewhat close together in orchard planting, say 12 to 20 feet apart, usually about 15 feet. Some varieties, particularly in the South, need 20 to 30 feet space. Putting a plum orchard down to grass is not admissible under any circumstances; but cultivation should cease with the first of July, or certainly by the middle of July; for the native plums are especially liable to make too much late summer growth. High manuring of the soil is not usually necessary, or even desirable; yet something considerably short of starvation will be found the best treatment for native plums.

F. A. WAUGH.

The plum in California.

The cultivation of the plum in California differs widely from that in the other plum-producing sections of the United States. Here the dreaded curculio is unknown, and while the equally dangerous black-knot has been found infesting a native wild cherry (*P. demissa*) it has never been observed in cultivated orchards. The most delicate varieties of the Old World find a very congenial home and form the basis of practically all orchard planting. In early mining days the California native plum (*Prunus subcordata*) was frequently cultivated, and before the introduction of European standard varieties attempts were made to improve the fruit by the usual methods of selection. Some very promising results were obtained; but since the demonstration of the great success of the more delicate and higher-flavored varieties, there has been little incentive to the use of the native species.

It seems hardly fair to make a distinction between "plums" and "prunes" in discussing this subject from the California standpoint. With the exception of the differences in the preparation for market, what may be said of the plum applies as well to the prune; for a prune is simply a plum which dries sweet without removing the pit. In most of the varieties of plums there occurs a

90,000 cases or 2,160,000 quarts; overland shipments, 7,906 carloads of fresh fruit.

The plum has an exceedingly wide range in California. It is thrifty and healthy on the immediate coast, in the interior and coast valleys, and well up into the foothills. This is perhaps most strikingly shown by the fact that every county in the state, except two perhaps (one being the city of San Francisco), contains plum or prune orchards, or both. When it is considered that this covers an area of nearly 160,000 square miles, extending through $9\frac{1}{2}$ degrees of latitude, a fair estimate of the adaptability of this fruit to varying conditions of soil and climate will be obtained. By choosing varieties ripening in succession, the California plum season may be extended from May to December. It is not surprising, then, that the acreage devoted to plums and prunes is one of the largest in the state, reaching a total of nearly 142,000 acres, an aggregate of nearly 11,000,000 trees, of which about four-fifths are prunes. Placer County leads in the acreage of plums with

5,500 acres, and Santa Clara in prunes with 58,400 acres. This great industry has developed since the discovery of gold. The early Mission plantings (1769–1823) included varieties of European plums, a few of which were able to survive after the abandonment of the Missions in 1834, by reproducing themselves by suckers. One variety found at Mission Santa Clara was grown and marketed as the "Mission prune" as late as 1870. The

3075. The americana type of plum.—Weaver (*Prunus americana*). (×1)

introduction of improved plum varieties, however, dates back to 1851, when the first grafted fruit-trees were brought to the state by Seth Lewelling from Oregon, where he and his brother had established nurseries in 1847. Prior to this introduction, however, the miners were supplied with fruit of the native plums. The first importation of prune cions from France by the United

States Patent Office in 1854 did not reach California. It was not until two years later that Pierre Pellier brought with him to San Francisco a small package of cions from the famous prune district of Agen, in France, which arrived in fairly good condition and were at once sent to Pellier's brother, Louis, who had already established a nursery and fruit-garden in the Santa Clara Valley, upon a portion of the site of the present city of San José. From these cuttings, a number of trees were produced which succeeded admirably, and eventually were distributed through different sections of the state, but principally in the Santa Clara Valley, which to this day remains the center of the California prune industry. In 1863, the first California-grown and -cured prunes were exhibited at the State Fair in Sacramento; but it was not until 1870 that planting on a commercial scale was begun. Through the seventies, and especially after 1873, numerous orchards were set out, until in 1881 some of the

3076. Flowers of native plums. *Prunus americana* on the left; *P. Munsoniana* on the right.

larger growers were producing between five and six tons of cured fruit. Since 1881 the growth of the prune industry has been marvelous, until now there are growers whose annual products reach hundreds of tons.

Considerable difficulty was at first encountered in the selection of the proper grafting stocks. The native species, first used to some extent, were soon found to be unsatisfactory, on account of suckering, and dwarfing effect. Peach, apricot, and almond roots were used, the peach and almond proving best. The introduction of the Myrobalan or French cherry-plum (*Prunus cerasifera*) and its adoption as a grafting stock for plums and prunes have greatly simplified matters. It does not sucker, and experience has shown that in California it succeeds in low moist lands, in comparatively dry soils, if not too loose, and in stiff upland clay soils. It thus has become the all-round plum stock in California. On deep mellow loam soils, specially adapted to the peach, that root is still preferred for plum stock; but many varieties, e.g., the Columbia, Yellow Egg, and the Washington, do not unite well with it, and cannot, therefore, be worked directly upon it. The almond is widely used in loose, warm, or rocky foothill soils, and the deep light valley loams for the French and Fellenberg prunes. The Myrobalan seedling, then, is used almost entirely, except in special cases, as an all-satisfactory grafting stock for the plum in California. Propagating the Myrobalan stock from cuttings

has been practically abandoned, and seedlings are now the rule. This is all-important in California, for there the roots of all plants must necessarily go deep for their moisture and nourishment. In fact, deep-rooting is the rule beyond all common expectation; thus almond roots the thickness of one's thumb have been found at a depth of 22 feet—one of the many instances of the characteristic conditions of California agricultural practice.

Propagation is by both buds and grafts. The usual practice is to bud the young stock in July and August, and then, in January and February following, all those which have not taken can be grafted, thus securing two chances. When peach or almond is used as stock, budding alone is done, as these stocks have been found to take the graft poorly. The trees are not allowed to remain in nursery longer than one year after budding, and in many cases are set out the spring following, as "dormant buds." In early days the tendency was to rather close planting, in some cases as close as 16 feet; but later plantings were made with wider distances, until from 20 to 24 feet has come to be the rule. The laying out of orchards has caused much discussion, some asserting that the quincunx, hexagonal, and triangular systems secure better use of the land and allow better access to plow and cultivator than do the plantings in squares. The square system, however, has come to be most generally used. The style of tree is the low-headed vase-form. The rule is to cut back the young trees at planting to 18 to 24 inches. Until the top is formed the stems are protected, by whitewashing or wrapping with burlap, from the hot afternoon sun. The first year from three to five branches are allowed to grow from the stem, and these used to form the main limbs of the tree. From this time the pruning is done according to the usual methods for the vase-form tree. Many plums, owing to the brittleness of the wood, are yearly pruned rather short but the French prune is able to carry fruit on much longer branches. After the third or fourth season, the growth of wood is much less and usually the pruning operations are confined to keeping the tree in shape, removal of dead or damaged branches, and shortening in the current season's growth to keep the young twigs in a vigorous growing condition and to prevent overbearing. The long slender branches are not cut back. The long arching "canes" are allowed to remain until they have produced a crop (which they do in the second season with the greatest profusion), the ends resting upon the ground as the fruit gains weight. When these droop too low, they are cut back to the crown, when others will be produced to take their places.

Thorough and persistent tillage is one of the first principles of the California orchardist, for with him the absence of summer rains makes the conservation of the winter rainfall an absolute necessity. Even in the summer-irrigated districts the soil is tilled and kept loose as soon as it is in proper condition, and no weeds allowed to rob the trees. Formerly all the prune and plum crop was produced without summer irrigation. Winter irrigation was often practised and the water conserved in the soil by the usual methods of tillage. But regular bearing of fruit of good size requires adequate moisture. The installation of pumping plants

3077. Wild Goose plum tree.

and irrigation systems, therefore, has received a great impetus, and the use of summer irrigation when required is an established practice.

In some of the older orchards, the need of fertilizing is beginning to be felt. In a great many, the main deficiency has been found to be vegetable matter, and, consequently, nitrogen. The extremely fine tilth which has been maintained has resulted in the destruction of all natural green growth and the "burning out" of the humus, and has necessitated the call for a green-manure crop. This problem is rendered more difficult in California by the fact that any such crop must be produced during the winter months and be ready to plow-in with the beginning of tillage in March; for no summer-growing crop can be allowed in the orchard, unless the land is regularly irrigated and then alfalfa may be grown. On non-irrigated orchards, winter-growth of hardy legumes, as vetches, is undertaken.

As mentioned above, the plum has few serious enemies in California, and none which cannot be held in check by spraying and other treatment. Upon the leaves the plum aphid and the canker-worm have given some trouble. The "peach-moth" has been found at work on the prune trees, but not to any serious extent. The trees are subject to the attacks of the black scale (*Saissetia oleae*), apricot scale (*Lecanium corni*), frosted scale (*L. pruinosum*) and pernicious scale (*Aspidiotus perniciosus*) being the most frequent; all of which, however, the California fruit-grower has learned to keep in check. The crown root-knot has also caused considerable trouble. Relief has been secured by cutting off the knots and painting the wounds with bordeaux mixture. In one district the peach root-borer has established itself and requires regular treatment. Thrips have also done some injury to blossoms and young fruit.

In California some fruit is usually borne the third year; in the fourth a fairly profitable crop is expected; the fifth, from 50 to 60 pounds to a tree should be produced, which ought to double in the sixth, and after that from 150 to 300 pounds is the rule. These figures apply mostly to the prunes. From 200 to 300 pounds are considered the average at full bearing in the Santa Clara Valley. In some instances 600 and even 800 pounds have been produced, and a six-year-old tree at Visalia (San Joaquin Valley) is credited with 1,102 pounds of fruit in one season.

It would be impossible to enumerate a full list of the varieties actually in successful cultivation within the state. Such a list would probably include every noteworthy variety of domestica plum. Many, however, despite excellence of quality and flavor, are suited only for home-growing, or at most for local markets, on account of poor shipping qualities. For this reason the number of varieties planted on a large scale is being constantly reduced. At the head of the list stands the Prune d'Agen,

the originally introduced French prune, which has proved itself adapted to more varying conditions than any other variety, and is therefore perhaps the most generally planted variety of fruit in the state. It is, of course, used chiefly for curing. In the same category belong the Robe de Sergeant, Imperial Epineuse, Silver, and Sugar—all drying varieties.

The Robe de Sergeant (supposed to be a synonym of the Prune d'Agen in France) in California is grown as a distinct variety. The fruit is larger, usually more highly flavored, and has commanded higher prices in the San Francisco market. The tree, however, has not proved so widely adaptable, and is in disfavor on account of defective bearing. The Silver prune (an Oregon seedling of Coe Golden Drop) is also a defective bearer in some districts, and is used mostly in the preparation of "bleached prunes," for which it has proved very profitable in some instances. It is sometimes marketed in the fresh state also. The Imperial Epineuse, a recently introduced French variety was largely planted but though large, it has proved rather irregular in bearing, difficult to cure and very subject to thrip injury. Luther Burbank's Sugar prune bases its claims upon superior earliness, sweetness and flavor, together with fair medium size. It dries easily but is of coarse texture. The German prune, Italian (Fellenberg), Golden prune, Hungarian (Pond Seedling) and Tragedy are varieties sometimes used for curing, but are frequently shipped green as "plums." Of these the German is perhaps the most extensively used. The Italian succeeds well along the coast in places liable to fogs or sea winds, where the French is not at its best. It is valuable as a late variety, and is said to dry excellently, as does also the Golden, an Oregon seedling. The fruit of the Hungarian (Pond) is very handsome and showy, and is rated, on its style, a good seller as fresh fruit in both the local and distant markets, but is not suitable for drying. The Tragedy and the Clyman (California seedlings), Giant (Burbank's), Royal Hative, Simon, and Peach, are popular for early market—especially for eastern shipment. For canning, Coe Golden Drop and the Imperial Gage are the most popular. The Jefferson, Washington, and Yellow Egg are all highly regarded, and planted more or less widely, as they suit the different climatic regions. Many of the Japanese plums are grown. Red June, Satsuma, Burbank, Wickson, Climax, Santa Rosa, and Formosa (all Burbank varieties) are prominent for eastern shipment, local market and domestic use.

See Wickson's "California Fruits and How to Grow Them," the Reports of the California State Board of Horticulture, and the Reports and Bulletins of the California Experiment Station.

ARNOLD V. STUBENRAUCH.
E. J. WICKSON.†

PLUM, CHERRY: *Prunus cerasifera*. P., Cocoa: *Chrysobalanus icaco*. P., Date: *Diospyros*. P., Governor's: *Flacourtia Ramontchi*. P., Japan: Properly *Prunus salicina*; improperly applied to the loquat, *Eriobotrya japonica*. P., Marmalade: *Lucuma mammosa*.

PLUMBAGO (from Latin *ior lead*, from the lead-colored flowers of some species, or because of some old tradition). *Plumbaginaceae*. LEADWORT. Subshrubs or herbs, often cultivated, particularly under glass, for the handsome phlox-like flowers.

Mostly perennial, sometimes climbing, often more or less woody; lvs. usually alternate and entire, clasping (or auricled) by the blade or by base of petiole; fls.

3079. Plum-rot. The mummy plums hang on the tree all winter.

3078. Fruit-spurs of a domestica plum. The letters indicate the termination of annual growths.

spicate or racemose on the ends of the branches, blue, violet, red, or white, gamopetalous, salverform, the tube usually slender; calyx tubular, 5-toothed, and somewhat angled, glandular; stamens usually 5, free from the corolla-tube, the filaments mostly with a dilated base; ovary attenuated at the top, the single style with

5 stigmas: fr. a membranaceous 5-valved caps.—About 10 or a dozen species inhabiting warm countries, chiefly of Eu., Asia, and Afr. For *P. Larpentæ*, consult *Ceratostigma*.

Two species of shrubby plumbagos, *P. capensis* and *P. rosea*, are deservedly well known. In the middle and northern states they are treated as greenhouse pot-plants and are usually turned out to flower in summer. They are readily prop. by cuttings taken either in autumn from plants growing in the open or in the spring from stock plants. They require an intermediate temperature.

A. Fls. red.

rôsea, Linn. (*P. sanguinea*, Hort.?). St., zigzag, more or less climbing, glabrous even in the infl.: lvs. large, ovate-elliptic, the short petiole somewhat

clasping; fls. purplish red, in long racemes, the corolla-lobes little if any exceeding the exerted part of the tube, the calyx glandular-hairy; base of style hairy. S. Asia. B.M. 230. Var. *coccinea*, Hook. (*P. coccinea*, Salisb.), is a form with larger scarlet fls. B.M. 5363. Gng. 1:183. H.T. II. 6:292. This is the form chiefly cult.—Like *P. capensis*, this species is useful for summer bedding. It is also an excellent subject for winter blooming in pots.

AA. Fls. blue or white.

B. Perennials, with more or less scandent sts.

capensis, Thunb. Fig. 3080. Semi-climbing shrub but a straggling upright plant as grown under glass, somewhat glaucous, glabrous except in the infl.: lvs. scattered, oblong-ovate to oblong-spatulate, nearly or quite obtuse and short-mucronate, narrowed into a very short petiole; racemes relatively short, the fls. sometimes appearing as if unbelled; fls. azure-blue, with a very slender tube $1\frac{1}{2}$ in. long and several times longer than the glandular-hairy cylindrical calyx-tube, the corolla-lobes obovate and phlox-like; caps. oblong-clavate, tapering and angled below. S. Afr. B.M. 2110. B.R. 417. Gn. 44, p. 380; 46, p. 245; 48, p. 344; 58, p. 20. G. 18:519; 27:41. Gn.W. 24:121. G.W. 10, p. 331. R.H. 1908:60. Var. *alba*, Hort., has white fls.—A well-known greenhouse plant. Old plants turned into the soil in late spring in a sunny exposure bloom profusely until frost. Plants struck from fall cuttings also give good bloom the following summer, but younger plants usually do not bloom so well. Plants can be kept in a cellar during winter, or they may be grown under glass for spring and summer bloom. It is an excellent rafter plant. In S. Calif. it climbs trees 15–20 ft. high if undisturbed. *P. capensis* and the white-flid. varieties are the commonest kinds.

zeylanica, Linn. Half-climbing, much branched, glabrous except the infl., which is glandular-hairy: lvs. ovate or oblong, obtuse or acute, the base of the short-winged petiole clasping the st.: fls. white, shorter than in *P. capensis*, the exerted part of the tube scarcely longer than the obovate retuse corolla-lobes, the calyx glandular-hairy: caps. long-oblong, 5-grooved above. Tropics of Asia and Afr., and east to Austral. and Hawaii. B.R. 32:23.—Little grown now, as it is inferior to the white-flid. form of *P. capensis*. Distinguished from that species by its shorter fls. and different lvs.

scandens, Linn. Somewhat woody, trailing or climbing, much branched, glabrous, the branches grooved; corolla white with mucronate lobes, the tube twice longer than the glandular-hairy calyx-tube; stamens 4, exerted; lvs. ovate-lanceolate to oblong-lanceolate, pointed, stalked. Trop. Amer., and also in southernmost parts of U. S.

BB. Annual, with erect sts.

cærulea, HBK. Erect annual, $1-1\frac{1}{2}$ ft. tall, with branched terete sts.: lvs. more or less rhomboidal, tapering to a winged and auricled petiole, glabrous and entire, the upper ones smaller: fls. small but rich in color, few and separate in a terminal spike, the tube purple and twice longer than the calyx, the segms. oval and acute, deep bluish purple with dark line in center; filaments not dilated. Peru. B.M. 2917 (as *P. rhomboidea*).

L. H. B.

PLUMERIA (Charles Plumier, 1646–1706, distinguished French botanist). Also spelled *Plumiera* and *Plumieria*. *Apocynaceæ*. Tropical trees grown for their showy and very fragrant flowers.

Leaves alternate, penninerved, the primary veins joined to a nerve running parallel with the margin: fls. in terminal 2–3-chotomous cymes; bracts usually large and covering the young buds but deciduous long before anthesis; corolla-tube cylindrical throughout; stamens included, near the base of the tube; disk wanting or fleshy and covering the tube of the calyx; ovules in many series: follicles 2.—About 50 species, all Trop. American, of which 2 kinds at present are offered in S. Calif. and 2 in S. Fla. The species are much confused and imperfectly understood.

Plumerias are amongst the most fragrant of tropical flowers, vying in this respect with the jessamine, Cape jasmine, and tuberose. They have large waxy funnel-shaped flowers with 5 spreading lobes of white, yellow, rose-purple, or combinations of the three colors. Choice specimens have been known to bear clusters 9 inches across, composed of more than twenty flowers each $3\frac{1}{2}$ inches across. They are considerably cultivated in all tropical lands. In the Pacific islands, *P. acutifolia* is frequent in graveyards. The word frangipani is supposed to be from the French, *franchipanier*, coagulated milk, referring to the tenacious white juice which exudes plentifully from the wounded plant. Other accounts suppose it to have come from an Italian nobleman of that name who in the Middle Ages compounded a perfume of many ingredients and which the odor of these flowers resembled. All species are likely to be called frangipani. Plumerias are essentially summer-growing plants. Keep rather dry in

3081. *Plumeria acutifolia*.

3080. *Plumbago capensis*.
($\times \frac{1}{2}$)

winter. Propagation is by cuttings in February or March.

A. *Fls. more or less rosy.*

rûbra, Linn. FRANGIPANI. Low tree or shrub: lvs. 5-8 in. long: cymes spreading; corolla-lobes broadly oval, longer than the tube. Mex. to Guiana and Ecuador; naturalized in W. Indies. B.R. 780 (fls. chiefly golden, only the tips bright rose). B.M. 279.—In W. Indies sometimes called "West Indian red jasmine."

AA. *Fls. chiefly white or yellow.*

B. *Lvs. narrow, oblong-linear.*

âlba, Linn. Lvs. rounded or acuminate at top, revolute at margin, tomentose beneath; veins rectangular-transverse: fls. white. W. Indies.—*P. hypoleuca*, Gasp., is probably a color variety, with yellow fls.

BB. *Lvs. wedge-shaped to lanceolate.*

acutifolia, Poir. (*P. acuminata*, Ait.). FRANGIPANI. Figs. 3081, 3082. Lvs. acuminate, often 1 ft. or more long, 3 in. wide, broadly lanceolate, with a long tapering base: corolla-lobes oval. Mex. B.M. 3952 (fls. white, much flushed from the center with pale yellow). *P. acuminata* of B.R. 114. H.U. 4, p. 161, with its narrow oblong lobes and close well-defined golden center, may be a different species though commonly considered the same.—Cult. in all tropical countries for the fragrant whitish fls.; flowers all the year. Also known as the temple-flower and graveyard-flower.

The following species have been intro. and more or less cult. abroad: *P. bicolor*, Ruiz & Pav. Tree, up to 40 ft. high: lvs. oblong, acuminate, margins revolute: fls. white, yellow at throat. Peru. B.R. 480. J.H. III. 56:19.—*P. Jamesonii*, Hook. Four feet high: lvs. mostly at tips of branches: fls. yellow, deeply tinged with red. Ecuador. B.M. 4751.—*P. Lambertiana*, Lindl. Ten feet high: lvs. oblong, acuminate, flat: fls. white, yellow-throated, with broad-rhomboid obtuse segms. May to Aug. Mex. B.R. 1378.—*P. lutea*, Ruiz & Pav. Ten to 20 feet high: lvs. crowded at ends of branches, 8-18 in. long, oblong-ovate: fls. white, flushed very pale pink with a broad pale golden yellow center. Peru. B.M. 5779. G.C. III. 39:406.—*P. tricolor*, Ruiz & Pav. (*P. Kerii*, Don). Fifteen feet high: lvs. obovate-oblong, tapering at both ends: fls. with a yellow throat, white above the yellow and bright rose around the segm. margin. July-Oct. Peru. B.R. 510.—*P. tuberculata*, Lodd. Six feet high: branches tuberculate: lvs. coriaceous, narrow-oblong, tapering into the petioles: fls. white, scentless. Aug. Santo Domingo.

WILHELM MILLER.

F. TRACY HUBBARD.†

3082. Flowers of *Plumeria acutifolia*. ($\times \frac{1}{2}$)

PŌA (ancient Greek name for grass or fodder). *Gramineæ*. Mostly perennial grasses of low growth, several species of which are cultivated for forage and a few for ornament.

Spikelets 2-6-fld., in open panicles; glumes shorter than the lemmas, awnless; lemmas keeled on back, membranaceous, scarious-margined, awnless, 5-nerved,

often cobwebby at base.—About 100 species, natives of temperate and cold regions.

A. *Plants tufted, without creeping rootstocks.*

trivialis, Linn. ROUGH-STALKED MEADOW-GRASS. Resembles *P. pratensis*, from which it differs by having no creeping rootstocks, taller sts., scabrous sheaths, branches of panicle more slender and spreading, usually only 2-fld. spikelets, the lateral nerves of lemma much more conspicuous. Native of Eu., where it is a prominent pasture grass; rather sparingly cult. in this country, where it is recommended for wet pastures. Dept. Agric., Div. Agrost., Bull. No. 17:243.—A variegated form is described as var. *foliis albo-vittatis*. F.S. 16: 1695.

nemorâlis, Linn. WOOD MEADOW-GRASS. Panicle long and narrow, with short branches; culms 1-3 ft.; glumes 3-nerved, acuminate. Native of Eu.—Recommended for pasture or lawn in shaded situations.

3083. June-grass.—*Poa pratensis*. ($\times \frac{1}{2}$; flower enlarged)

AA. *Plants producing creeping rootstocks, thus forming a sod.*

B. *Fls. diæcious.*

arachnifera, Torr. TEXAS BLUE-GRASS. Culm 2-3 ft. high; panicle contracted, 3-8 in. long; spikelets $\frac{1}{4}$ in. long; first glume 1-nerved, second 3-nerved; lemma copiously webby-hairy at base. A native of Texas, where it is a valuable forage grass.—It prop. by rhizomes and forms a dense sod. Recommended as a winter pasture-grass in the S. Easily distinguished from the other species by its contracted panicle and large spikelets. Dept. Agric., Div. Agrost., Bull. No. 17:246.

BB. *Fls. perfect.*

compressa, Linn. Known in the trade as CANADA BLUE-GRASS (though it is probably not native to Canada) and ENGLISH BLUE-GRASS, but the latter name is often applied to *Festuca pratensis*. Distinguished from *P. pratensis*, which it resembles, by its blue-green foliage, distinctly flattened culms, and its short and much contracted panicles. Spreads by rhizomes. Native of Eu. and extensively naturalized in this country, being found in open and rather sterile soil. Dept. Agric., Div. Agrost., Bull. No. 17:248.—It is of little value as a pasture grass except possibly on sterile soil.

pratensis, Linn. KENTUCKY BLUE-GRASS. JUNE-GRASS. Fig. 3083. Panicle pyramidal, open, usually 3-4 in. long; spikelets 3-6-fld., $\frac{1}{2}$ in. long; first glume 1-nerved, second 3-nerved; lemma cobwebby at base; culm usually 1-2 ft. high, forming a sod with its copious rootstocks, its long soft basal lvs. producing an abundance of foliage. Native in the cooler regions of the northern hemisphere. Dept. Agric., Div. Agrost., Bull. No. 20:148.—A common pasture-grass through the middle part of the U. S. Its most important horticultural use is for lawns, for which purpose its habit and aggressiveness are eminently adapted.

A. S. HITCHCOCK.

PODACHÆNIUM (Greek, *foot* and *achene*, alluding to the base of the achenes). *Compositæ*. Tall shrubs, one of which in southern California is said to attain a height of 30 feet, cultivated chiefly for their large and fragrant leaves.

Leaves opposite, large and angular-lobed: heads small, disposed in a broad corymbose panicle; fls. with white rays and yellow disk: achenes sparingly pilose.—Two or 3 species, Mex. to Colombia. The principal species of Podachænium, *P. eminens*, is commonly cult. under the name of Ferdinandia, which is really the oldest generic name, but this name is also used for some species of Zaluzania. The distinguishing feature of Podachænium is the shape of the achene, which is contracted at the base into a 2-winged stipe suggesting the shape of a foot. In the N. and in Eu., they are grown in the warmhouse, but they are quite hardy in the open in the S.—The fl.-heads are about 1 in. across, and about 20 or more in terminal flat-topped clusters, borne in winter and spring.

éminens, Baill. (*P. paniculatum*, Benth. *Ferdinandia éminens*, Lag. *Zaluzania éminens*, Hort. *Cosmophyllum cactifolium*, C. Koch). A tall shrub, 9-15 ft. high, slightly branched: lvs. opposite, suborbicular or broad-ovate, base short- or long-cuneate, slightly 5-7-lobed or subentire, rather scabrous above, cinerous or subtomtose pubescent beneath: ray-fls. white, disk-fls. yellow. Mex., Guatemala. R.H. 1862, p. 110. B.M. 8502.

andinum, André. Lvs. large, coarsely lobed: fl.-heads in loose corymbs; ray-fls. white, disk-fls. yellow. Colombia. R.H. 1892, p. 414.—Said to be a useful plant for subtropical bedding.

F. TRACY HUBBARD.

PODALÿRIA (named for Podalyrius, the son of Æsculapius). *Leguminosæ*. Shrubs, with alternate simple lvs. which have subulate often deciduous stipules: infl. axillary, 1-2-, rarely 3-4-fld.; calyx broad-campulate, toothed or subequally lobed; petals subequal in length, standard suborbiculate, emarginate, slightly longer than the wings, with a short recurved claw, wings obovate, oblique, keel shorter than the wings, broad-obovate, slightly incurved; stamens free or very shortly connate at base; ovary sessile, villous, many-seeded: fr. an ovoid or oblong turgid pod with leathery valves.—About 20 species, all of them S. African. *P. sericea*, R. Br. AFRICAN SATIN-BUSH. Erect or procumbent, 4-6 ft. high, the whole plant with a satiny or silvery luster, sometimes fulvous: branches silky: lvs. obovate or cuneate-oblong, acute at base, silky on both surfaces: fls. pale-purple, solitary on the peduncles; calyx silky, lobes subulate acute, as long as the carina: fr. a silky pod. Cape Colony. Intro. into S. Calif. and also cult. abroad. The following species are mentioned as having been cult.: *P. argentea*, Salisb., *P. buxifolia*, Willd., and *P. calyptрата*, Willd.

PODÁNDRIA (Greek, *foot* and *man* or *anther*, probably referring to long-stipitate anthers). *Orchidacæ*. Terrestrial herb with radical petioled lvs. and large-fld. racemes: sepals free, lateral narrower than the dorsal, reflexed; petals simple, filiform-setaceous, erect, longer than the dorsal sepal and free from it; lip continuous with the column, shortly adnate to it, produced at the base into a long cylindrical spur; limb pendulous, 3-partite with narrow lobes, column with a short broad base, footless; anther long-stipitate, pollinia granular with very long slender caudicles; stigmas sessile, nearly confluent, situated within the side lobes of the rostellum and at their base, rostellum trilobed.—The only species is from W. Afr. The genus resembles Habenaria, in which it has been included, in habit but is remarkable for its enormously elongated anther and long narrow segms. *P. macrandra*, Rolfe (*Habenaria macrandra*, Lindl.). Plant $\frac{3}{4}$ -1 $\frac{1}{4}$ ft. high, apparently evergreen: lvs. elliptic-oblong, 2-5 in. long: racemes 2-9-fld.; fls.

large, white with a green tint on the sepals. G.C. III. 54:182. Intro. abroad and cult. by some orchid fanciers.

PODOCÁRPUS (Greek, *pous*, *podos*, foot, and *karpus*, fruit; alluding to the conspicuous fleshy footstalks of most species). Including *Nageia*, *Prumnopitys* and *Stachycarpus*. *Taxacæ*. Ornamental woody plants grown for their evergreen foliage.

Resinous evergreen trees, rarely shrubs: lvs. alternate, sometimes opposite or 2-ranked, sessile or short-stalked, linear to elliptic, entire: fls. monœcious or dioecious, axillary or subterminal, solitary or in spikes; the staminate catkin-like, consisting of spirally disposed, 2-celled anthers; the pistillate consisting of a scale inclosing the ovule, with several bracts at the base, which become usually much thickened at maturity, and form a fleshy receptacle bearing at the top the globular or ovoid drupe- or nutlike seed: cotyledons 2.—Fifty-five species, chiefly in tropical and subtropical mountains of S. Amer., W. India, Asia, Afr., and Austral. Some species with the fls. in spikes and the fr. without fleshy receptacle are separated by some botanists as *Prumnopitys* (*Stachycarpus*). Many species are valuable timber trees in their native countries, and the fleshy seed-stalks of some are eaten.

The podocarpaceae are evergreen often tall trees with usually narrow, rarely elliptic, dense foliage, small flowers, the staminate yellow, the pistillate greenish and inconspicuous, and with rather small, berry-like fruit borne on usually much thickened fleshy footstalks of dark purple or purplish violet color. They are but rarely cultivated in this country and only adapted for the southern states and California, except *P. alpina*, which is the hardest and may probably thrive as far north as Philadelphia, or even farther. They grow best in well-drained loamy soil. In the North they are sometimes grown as pot-plants in greenhouses on account of their handsome foliage; a sandy compost of loam and peat will suit the potted plants. Propagation is by seeds or by cuttings of almost ripened wood under glass; they are also sometimes grafted on any of the species which can be had in quantity.

A. Lvs. 1-8 in. long.

B. Under side of lvs. pale green or glaucescent.

C. Midrib of lvs. distinct above; width of lvs. $\frac{1}{2}$ in. or less.

macrophylla, Don (*P. longifolia*, Hort.). Tree, attaining to 50 ft., with horizontally spreading branches and pendent branchlets: lvs. alternate, pinkish when unfolding, more or less spreading, narrowly lanceolate, narrowed toward the apex and acute or obtusish, at the base gradually narrowed into a short petiole, bright green and lustrous and with a distinct midrib above, paler below, 3-4 in. long and more than $\frac{1}{2}$ in. broad: staminate fls. fascicled, sessile, about 1 in. long: seed ovoid, $\frac{1}{8}$ - $\frac{1}{2}$ in. long, borne on a fleshy purplish violet receptacle. Japan. S.Z. 2:133. S.I.F. 1:13. G.W. 14, p. 322. Var. *Máki*, Sieb. (*P. chinensis*, Wall. *P. macrophylla* var. *chinensis*, Maxim. *P. japonica*, Sieb.). Branches upright: lvs. more upright, linear-lanceolate, obtuse or obtusish, $1\frac{3}{4}$ -3 in. long and $\frac{1}{4}$ - $\frac{1}{4}$ in. broad, with distinct midrib above: seed globose-ovoid, $\frac{1}{2}$ in. long or slightly longer. Japan, China. S.Z. 2:134. R.H. 1848:41.—Several variegated forms of this variety are in cult.

neriifolia, Don. Tree, to 70 ft., with spreading much-ramified branches: lvs. scattered, sometimes indistinctly whorled, spreading, lanceolate or narrow-lanceolate, gradually long-acuminate, at the base narrowed into a short petiole, dark green above and with the slightly raised narrow midrib in a groove, slightly glaucous beneath, 3-6 in. long, in young plants sometimes to 10 in. long, about $\frac{1}{2}$ in. broad: staminate fls. solitary or 2-3, sessile, 1-2 in. long: seed ovoid, $\frac{1}{2}$ in. long or slightly longer, with a fleshy receptacle nearly $\frac{1}{2}$ in.

long, on a stalk about $\frac{3}{4}$ in. long. Himalayas and S. W. China to New Guinea. B.M. 4655. F.S. 8:768. J.F. 3:313.

cc. *Midrib of lvs. indistinct above; width of lvs. $\frac{1}{4}$ in. or less.*

gracilior, Pilger. Tree, to 60 ft., with scattered or whorled branches: branchlets slender, winged by the decurrent lvs.: lvs. alternate, linear-lanceolate, gradually acuminate, more or less falcate, spreading, midrib indistinct above, 2-4 in. long and $\frac{1}{6}$ - $\frac{1}{4}$ in. broad: staminate fls. 1-3, axillary, $\frac{3}{4}$ -1 $\frac{1}{4}$ in. long: seed subglobose, $\frac{1}{2}$ - $\frac{3}{4}$ in. long, on a scaly, not thickened stalk. Cent. Afr.

elongata, L'Hér. Tree, to 70 ft., with more or less whorled, densely leafy branches: lvs. alternate, erect-spreading, narrowly linear-lanceolate, gradually narrowed at the apex and acute, nearly pungent; midrib inconspicuous above, $1\frac{1}{2}$ -2 in. long and about $\frac{1}{6}$ in. broad: staminate fls. solitary, axillary, sessile, about $\frac{3}{4}$ in. long: seed globose, $\frac{1}{3}$ in. across, with a short fleshy receptacle on a slender stalk about $\frac{1}{4}$ in. long. S. Afr.

BB. *Under side of lvs. with 2 glaucous lines.*

nubigena, Lindl. (*Saxegóthia gracilis*, Hort.). Tree, or in cult., shrub: lvs. spreading, crowded, linear-lanceolate, acute and mucronate, pungent, somewhat revolute at the margins, dark green and with a prominent midrib above, with 2 white bands beneath, 1-1 $\frac{3}{4}$ in. long: fls. dioecious, the staminate clustered, $\frac{1}{2}$ -1 in. long: seed ovoid, $\frac{1}{3}$ in. long, on a fleshy receptacle, very short-stalked. Chile. G.C. III. 10:171.

AA. *Lvs. $\frac{1}{3}$ - $\frac{3}{4}$ in. long.*

alpina, R. Br. Shrub or small tree, attaining 15 ft., with spreading branches: lvs. indistinctly 2-ranked, linear to linear-oblong, obtuse, mucronulate, dark green, grooved or flat above, pale green beneath, $\frac{1}{2}$ - $\frac{3}{4}$ in. long: fls. dioecious, the staminate solitary or clustered, about $\frac{1}{3}$ in. long: seed $\frac{1}{5}$ in. long, on a fleshy receptacle. Austral.

P. andina, Poepp. (*Prumnopitys elegans*, Phil. *Stachycarpus andina*, Van Tiegh.). Tree, attaining 20 ft., with upright or somewhat spreading branches: lvs. indistinctly 2-ranked, linear, dark green above, slightly glaucous beneath, $\frac{1}{2}$ -1 $\frac{1}{2}$ in. long: fls. in spikes: receptacle not fleshy. Chile. G.C. III. 31:121. J.H.S. 37, p. 52.—*P. Bidwillii*, Hoibr.—*P. spinulosa*—*P. chilina*, Rich.—*P. saligna*—*P. coreana*, Hort., incorrect spelling for *P. koraiana*—*Cephalotaxus Harringtonia* var. *fastigiata*—*P. coriacea*, Rich. Tree, attaining 50 ft., with spreading branches: allied to *P. macrophylla*: lvs. lanceolate, acuminate, 2-4 in. long: fr. ovoid. Jamaica. Sometimes *Cephalotaxus* drupacea is cult. under this name.—*P. dactyloides*, A. Rich. Tall tree: lvs. dimorphic, on young plants linear, spreading, 2-ranked, $\frac{1}{2}$ - $\frac{1}{2}$ in. long, on older plants shorter, imbricate, appressed or spreading: seed ovoid, small: receptacle scarlet, $\frac{1}{4}$ in. long. New Zeal. G.W. 6, p. 594.—*P. formosensis*, Dümmer, from Formosa, allied to *P. Nagi*, but with smaller and thicker, lance-elliptic, obtusely truncate lvs., is not yet intro. G.C. III. 52:295.—*P. jamaicensis*, Hort.—*P. Purdieana*—*P. koraiana*, Sieb.—*Cephalotaxus Harringtonia* var. *fastigiata*—*P. montana*, Lodd. (*P. taxifolia*, Kunth. *Prumnopitys taxifolia*, Mast.). Tree, attaining 60 ft., with spreading branches: lvs. 2-ranked, linear, acute or obtuse, abruptly narrowed into a short petiole: fls. in spikes: no thickened receptacle. Peru, Colombia.—*P. Nagi*, Pilger (*P. Nageia*, R. Br. *Nageia japonica*, Gaertn.). Tree, attaining 90 ft., with spreading, sometimes pendulous branches: lvs. mostly opposite, ovate to oblong-lanceolate, short-acuminate, 2-3 $\frac{1}{2}$ in. long, bright green and glossy: fr. $\frac{3}{4}$ in. across, subglobose. Japan. S.Z. 2:135. R.H. 1914, p. 77.—*P. pectinata*, Panch. (Acemopyle Pancheri, Pilger). Tree, to 60 ft.: lvs. dimorphic, either linear, obtuse or acute, with 2 white bands beneath, about $\frac{1}{2}$ in. long, or minute, acuminate, scale-like, appressed: staminate fls. terminal: seed globose, $\frac{1}{4}$ in. across, with a thickened receptacle. New Caledonia. B.M. 7854.—*P. Purdieana*, Hook. Tree, to 120 ft., with whorled horizontal branches: allied to *P. macrophylla*: lvs. oblanceolate, obtuse, mucronulate, bright green, 2-5 in. long, $\frac{3}{4}$ in. wide. Jamaica. H.I. 7:624.—*P. saligna*, Don (*P. chilina*, Rich.). Tree, attaining 60 ft., allied to *P. macrophylla*: lvs. linear-lanceolate, acute, slightly falcate, 3-4 $\frac{1}{2}$ in. long: staminate fls. clustered, about 1 in. long. Chile, Peru.—*P. spicata*, R. Br. (*Prumnopitys spicata*, Mast.). Tree, attaining 80 ft.: lvs. 2-ranked, linear, obtusish, sessile, $\frac{1}{4}$ - $\frac{1}{2}$ in. long: fls. in spikes: receptacle not thickened. New Zeal. H.I. 6:543.—*P. spinulosa*, R. Br. (*P. Bidwillii*, Hoibr.). Allied to *P. macrophylla*. Tree: lvs. upright, linear, acuminate and spiny-pointed, midrib distinct above, $\frac{1}{2}$ - $\frac{3}{4}$ in. long. Austral.—*P. taxifolia*, Kunth—*P. montana*—*P. Totarra*, A.

Cunn. (*P. Totara*, Don). Tree, attaining 90 ft. with spreading branches: allied to *P. alpina*: lvs. linear, acute or acuminate, $\frac{1}{2}$ -1 $\frac{1}{4}$ in. long. New Zeal.

ALFRED REHDER.

PODÓLEPIS (Greek, *foot and scale*; referring to the unusual fact that the involucre scales have a foot-stalk or claw). *Compositæ*. Australian herbs with yellow, pink or purple rays, a few of which are cultivated as half-hardy annuals.

Plants 6-12 in. high and bearing fls. which are chiefly interesting as representing an intermediate stage between the common type of composite with showy rays and the "everlasting fls." like *Helichrysum*, in which the rays are aborted and the showy parts are the stiff involucre scales. In *Podolepis* the involucre scales are generally colored, but are thin and nearly transparent, and overlap one another instead of standing out like petals.—About 16 species belonging to an unfamiliar group of composites from Australia. Very little in cult. in America. The following species are annuals with linear or lanceolate lvs. and hemispherical involucre $\frac{1}{2}$ - $\frac{3}{4}$ in. diam. They need a porous soil with full exposure to the sun, and they also do well in pots. See *Annuals*.

3084. *Podolepis aristata*. ($\times \frac{1}{2}$)

A. *Color of rays yellow.*

B. *Involucre bracts acute.*

canescens, A. Cunn. (*P. affinis*, Sond.). Rarely much exceeding 1 ft.: lvs. mostly all basal, linear or linear-lanceolate, 1-2 in. long: involucre bracts slightly or not at all rugose; claws with broad scarious margins: rays 3-4-lobed slightly longer than the disk-fls.

BB. *Involucre bracts acuminate.*

aristata, Benth. (*P. chrysantha*, Endl.). Fig. 3084. Often exceeding 1 ft.: lvs. linear or lanceolate mostly st.-claspings and decurrent: involucre bracts not rugose, usually ending in a rigid point or awn, the claws of the inner ones narrow and glandular: rays longer than the disk-fls., 3-4-lobed. R.H. 1857, p. 263.

AA. *Color of rays purple or lilac.*

gracilis, Graham. Often exceeding 1 ft., the smooth st. usually much branched: lvs. linear, st.-claspings and often slightly decurrent: involucre bracts obtuse; claws narrow, glandular: rays entire or 2-lobed, $\frac{1}{2}$ in. long: pappus not thickened upward. B.M. 2904 (disk-fls. mostly purple, some yellow). WILHELM MILLER. N. TAYLOR.†

PODOLBIUM: *Oxylobium*.

PODOPHYLLUM (from Tournefort's *anapodophyllum*, duck's-foot-leaf; from a fancied resemblance in the foliage). *Berberidaceæ*. MAY APPLE. MANDRAKE (erroneously). Herbs common in rich woods and copses throughout the eastern United States, a colony of which is most desirable for a wild garden.

Hardy perennials herbs: sepals 6, petal-like; petals 6-9: stamens as many or twice as many as the petals;

pistil 1 (rarely several): berry with many seeds, which are inclosed in fleshy arils.—*Podophyllum* is a genus of about 5 species,—1 American, 1 Himalayan and 3 from China.

The May apple is one of the most prominent of the native low-growing spring herbs. The "apples" are yellowish egg-shaped fruits about 2 inches long, and have a rather mawkish taste. The leaves are very distinct, being shaped like a round shield with 5 to 7 lobes. The plant has two kinds of leaves, the solitary ones, and the others in pairs. The large centrally peltate leaves have no flower underneath. The flowers are nodding white waxlike cups which spring from the fork of the stem. They have a rather unpleasant smell.

Some parts of the May apple plant are emetic and poisonous. Extract of *podophyllum* is common in drug-stores. For the drug trade, the rhizomes are collected late in summer and dried, the supply coming mostly from the Central States.

The plants are offered by several dealers in hardy herbaceous perennials. They are of easy culture, re-

3085. Royal poinciana.—*Poinciana regia*.

quiring deep rich soil and partial shade. They are useful only for spring effects, however, as the foliage dies down by midsummer or before. Later-growing vigorous perennials, as *Polygonatum giganteum*, may be associated with a planting of May apple, to occupy the ground in the later part of the season. *P. Emodii* requires a moister situation, and some prepare a peaty soil for it. Propagation is by division or by seed. The mandrake of Old World history and romance, is *Mandragora*.

A. Frs. yellowish.

peltatum, Linn. MAY APPLE. MANDRAKE (see *Mandragora*, Vol. IV, p. 1982). Height 1-1½ ft.: lvs. dark green, nearly 1 ft. across, 5-7-lobed, each lobe 2-cleft: fls. about 2 in. across. Also called wild lemon and hog apple. B.M. 1819. Gn. 21, p. 127. B.B. 2:92.—Blossoms in April and fruits in May. It is a shade-loving species, although growing also in partial sun in moist and rich soil, from W. Quebec and W. New Eng. to Minn. and south to Fla. and Texas.

AA. Frs. deep red.

emodii, Wall. Lvs. 3-5-lobed: fls. white or pale rose: fr. large as a hen's egg, brilliant red. Himalayas. G.C.

II. 18:241.—The foliage is a fine bronzy red in early spring, said to be edible.

P. versipelle, Hance. A perennial herb, with sts. about 3 ft. high, 2-forked at top, each fork bearing a lobed peltate lf.: fls. pendulous, crimson, in clusters of 12-16 just under the lvs. China. Intro. into England. B.M. 8154. F. TRACY HUBBARD.†

PODOSTÍGMA (Greek words referring to the fact that the stigma has a foot or stalk). *Asclepiadaceæ*. This includes a half-hardy tuberous-rooted perennial herb which grows a foot high or less in low pine-barrens from N. C. to Fla. and bears in summer small greenish yellow fls. The genus is closely allied to *Asclepias*, and is distinguished by having the hoods remote from the anthers at the base of the long column, while in *Asclepias* the hoods are approximate to the anthers. **P. pedicellata**, Vail. Lvs. opposite, linear-lanceolate, nearly sessile: peduncles terminal and axillary, umbellately several-fld. The only species.—Advertised in 1881, but presumably not hardy N.

POGONIA (Greek, *beard*; alluding to bearded labelum). *Orchidaceæ*. Hardy terrestrial orchids.

Mostly small perennial herbs, with erect slender sts.: fls. solitary or in racemes; sepals and petals free, erect or ascending; labellum sessile, with broad base, spurless, with longitudinal ridges.—About 40 species, N. and S. Amer., with exception of 2 Chino-Japanese species. *Pogonias* are delicate plants requiring care in planting. The woodland species should have rich leaf-mold, with deep shade; the swamp species require peat or suitable light, rich soil, moist yet not wet. All the species are preferably planted in spring.

A. *Sepals and petals nearly equal in length.*

ophioglossoides, Ker. St. 8-15 in. high, slender, 1-3-lvd.: lvs. 1-3 in. long, lanceolate or ovate: fls. solitary or in pairs, fragrant, pale rose, subtended by a foliaceous bract. June, July. In meadows and swamps, U. S. B.R. 148. G.F. 10:485. V. 2:269; 11:229.—This seems to be the only species that can be grown with success. It thrives in wet moss in boxes of sphagnum. Usually it is better to transplant from the wild each year than to attempt to prop. the plants. Sometimes it can be colonized in wet meadows.

AA. *Sepals longer than the petals.*

divaricata, R. Br. St. 1-2 ft. high, slender, bearing a solitary fl.: fl. 1 in. long; sepals dark; petals flesh-colored; lip as long as petals, greenish, veined with purple. July. Swamps, N. J. to Fla. B.B. 1:468.

P. pendula, Lindl.=*Triphora*.—*P. verticillata*, Nutt.=*Isotria*.

HEINRICH HASSELBRING.

POGOSTEMON (Greek, *bearded stamen*). *Labiatae*. This includes the plant which produces the well-known perfumes called patchouli, or in India pucha-pat.

Herbs or subshrubs: lvs. opposite, rarely in 3's: fls. small, in solitary or panicle spikes formed of many dense whorls; calyx subequally 4-5-toothed; corolla-tube exerted or included; limb sub-2-lipped; lobes 4, lower usually longest; stamens 4, exerted, straight or declinate; filaments usually bearded; anther-cells confluent: nutlets smooth, ovoid or oblong.—About 40 species, 24 of which are distinguished in Flora of British India 4:631.

Patchouli has a peculiar dry moldy smell and is one of the commonest perfumes in India. In the 1840's its presence was considered the sure test of a genuine Indian shawl, but the French manufacturers of imitation Indian shawls imported the perfume in the 1850's. Patchouli is no longer fashionable. Fuller accounts of it will be found in the "Cultural Industries of Queens-

land," V. 8:247 and Gn. 27, p. 447. The plant has no ornamental value. Live plants were introduced into southern California, and were offered in 1900 in the East.

Heyneanus, Benth. (*P. Patchouly*, Pellet.). **PATCHOULI PLANT**. Herb, 2-3 ft. high: lvs. long-stalked, ovate, acute, acuminate or obtuse, crenate, simply or doubly toothed: spikes terminal and axillary, forming a paniced infl.; whorls usually separate, forming interrupted spikes; fls. whitish, tinged purple. India and Burma.

POINCIANA (M. de Poinci, governor of the Antilles in the seventeenth century). *Leguminosæ*. Small mostly broad-topped unarmed trees, with large and very showy flowers; one of the most conspicuous trees in southern Florida and the American tropics.

Leaves bipinnate with numerous small lfts. and with no stipels and inconspicuous stipules: fls. very showy, orange or scarlet, in large corymbose racemes, not papilionaceous, the 5 petals clawed and eroded or even fimbriate on the margin, the stamens 10 and free and exserted: fr. long and flat.—There are 2 or 3 species of Poinciana, all native to the oriental tropics. The genus has been confounded with *Cæsalpinia*, but the calyx-segms. are valvate, whereas they are strongly imbricate (or overlapping) in *Cæsalpinia*. The *P. pulcherrima*, known as "Barbados pride" and "bird-of-paradise flower," is *Cæsalpinia pulcherrima*; *P. Gilliesii* is *C. Gilliesii*. *P. elata*, Linn., native to India, Arabia, and Trop. Afr., is planted in the Old World, but is not in the American trade. It reaches a height of 20-30 ft., with the petals scarcely exserted beyond the calyx.

Conzattii, Rose. Small tree, with grayish bark: lvs. glabrous, large, with commonly 4 pairs of pinnæ; lfts. 4 or 5 pairs, oblong to obovate: infl. a sessile raceme; sepals highly colored, obtuse; petals yellowish red: pod scythe-shaped, pubescent. Mex.—Cult. in Mex. and S. Calif.

regia, Boj. **ROYAL POINCIANA. PEACOCK FLOWER. FLOMBYANT**. Figs. 3085-3087. Rapid-growing tree, reaching 20-40 ft., and making a wide-spreading picturesque top: lvs. 1-2 ft. long, with 10-20 pairs of pinnæ, each pinna with numerous oval lfts.: fls. 3-4 in. across, bright scarlet (upper petal striped with yellow and more cuneate), the obovate petals very prominently clawed (or narrow below): pod 6 in. to 2 ft. long. Madagascar. B.M. 2384.—Now a popular tree in frostless countries, as in S. Fla., S. Calif., Bermuda, and the W. Indian Isls. It is deciduous. One of the most striking and gorgeous of tropical trees. Sometimes seen under glass in the N. *Cæsalpinia pulcherrima* is often confounded with it; but that plant is a shrub or at most only a small tree, with strongly overlapping calyx-segms. in the bud, smaller fls., and very long-exserted stamens. L. H. B.

POINSETTIA (*Euphorbia pulcherrima*, which see), is one of the most popular plants for the Christmas season. It is a

shrub of tropical America with inconspicuous flowers but with flaming red leaves or bracts (with variations to pink and white), clustered near the top. It is for these leaves that the plant is grown (Fig. 1440, Vol. II).

3087.
Poinciana regia.

3086. Poinciana regia. (× 1/2)

rather tall to be of much use for decorative purposes. Pot the cuttings singly in small pots in sand. It is better to have a little sphagnum moss in the bottom of each pot for the roots to grip. Place them in a tight case shaded from the sun. The temperature should never be less than 65°. Water the cuttings every morning until they root, except on dull days. When rooted, pot them in 3½-inch pots in equal parts of loam, leaf-mold, and sand. The next shift may be a 6-inch pot, and a good fibrous loam with a sixth part of sheep-manure added. They will form a fine large bract in this size pot, and require no further potting although they should be fed with manure-water until the yellow flower appears in the center of the bracts. After the first batch of cuttings has been removed, the stock plants should be planted out-of-doors. One gets far firmer and as many cuttings by this treatment, and the cuttings now secured and rooted may be used in various ways. Twelve cuttings rooted as advised above and placed in a 10-inch pot make a fine specimen plant for Christmas. Others may be grown about 2 feet high for single-stem plants. The last cuttings to be rooted for the season should be secured not later than the middle of August, and they are excellent for making up shallow pans for centerpieces for Christmas. Poinsettias should at all times be grown as near the glass as possible, and during the summer months the house should have full air day and night. Never, however, allow the temperature to drop below 60°, and avoid draughts, as this will tend to make the foliage drop, and the retaining of the leaves is one of the attractive points in a well-grown plant of poinsettia. Insect pests that attack the poinsettia can be eradicated by the use of hydrocyanic gas, as advised for other plants.

GEORGE F. STEWART.

POISON BERRY: *Cestrum*. P. Dogwood: *Rhus vernix*. P. Elder: *Rhus venenata*. P. Hemlock: *Conium maculatum*. P. Ivy: *Rhus Toxicodendron*. P. Oak: *Rhus Toxicodendron*. P. Sumac: *Rhus vernix*.

POISONOUS PLANTS. The plants that are injurious to man and the domestic animals may be divided into two groups: (1) those that cause injury by mechanical means; and (2) those that are poisonous.

3088. Leaf of poison ivy. ($\times \frac{1}{2}$)

The first group includes those plants which are mainly harmful to farm cattle, causing serious troubles which may result eventually in the death of the animal. This group includes such plants as the crimson clover, *Trifolium incarnatum*, spiny cacti (*Opuntia*), the hairs and spines of which form the hair-and-spine-balls known as phyto-bezoars. The branched hairs of the calyx of the crimson clover, if eaten by horses and cattle, when in full flower, are rolled together to form the hair-balls which have been responsible for the death of many animals. The spines of species of *Opuntia* in Mexico and the southwestern United States cause the laceration of the mouth and tongue of cattle and death has resulted in a number of cases, where these spines have been rolled into phyto-bezoars. *Ægagropilæ* are balls formed from animal hairs which have been licked off and swallowed. Through the peristaltic movement of the intestines these have been rolled into balls. The silex in the stems of the scouring-rushes (*Equisetum*) is responsible for inflammation of the digestive organs of cattle. The hygrometric structures attached to the fruits of such grasses as *Stipa capillata* (Russia), *S. spartea* (United States), *Aristida hygrometrica* (Queensland), and *Heteropogon contortus* (New Caledonia), by their spiral movements cause the pointed ends of the fruits to bore into the skin and flesh of animals in those regions of the earth. The blue-mold, *Aspergillus fumigatus*, which lives at blood temperature, penetrates the lung tissues of calves and pigeons, and its masses of spores fill up the air-cavities and lung-passages, causing asphyxiation. These are some of the illustrations of plants that kill, or cause injury, by mechanical means.

The poisonous plants, however, are those that contain some chemical poison which either produces irritation, disease, or death by its direct action. The season of the year has a direct influence on the activity of a poisonous plant. Melter (1899) records that his horse ate 500 pounds of the dried hay of *Passiflora incarnata* in August without injury, while in March, eight months later, 25 pounds of the hay of this plant

killed another horse. The condition or age of the plant is important. The poisonous principle in the spotted hemlock, *Conium maculatum*, is volatile, and hence the dried plant is less poisonous than the fresh. The leaves of wild black cherry, *Prunus serotina*, are more poisonous when dry than when fresh, owing to the development of hydrocyanic acid. Some parts of a plant are more poisonous than others. For example, the seeds of the Jamestown weed, *Datura Stramonium*, are more deadly than the remainder of the plant. Again it may be said that the relative amounts of poisonous substance vary in different individuals of the same species and that small doses of some poisons are taken with beneficial results, for instance the use in medicine of belladonna, strychnine, and aconite. The toxic properties of plants are not due in all cases to the same chemical substance. It is well known that several plants contain a number of toxic bodies. For example, the green hellebore, *Veratrum viride*, contains the alkaloids jervin, cevadin, and veratrin. Sometimes the same poison is present in more than one species, as solanin in the tomato and the potato. Not all animals are equally affected by the same poison, as for example, the darnel which poisons men, dogs, horses, and sheep, but is innocuous to cows, pigs, and ducks. Some persons are susceptible to poison ivy, others are not. This susceptibility may be increased by sickness, or a run-down condition. Some animals acquire a craving for certain injurious plants, as for example, the loco weeds of the United States, stemless loco weed, *Oxytropis Lambertii*, and in Australia, according to Maiden, the indigo plant, *Swainsona galegifolia*. Kobert divides poisonous plants into three groups: (1) irritants which cause gross anatomic changes, as croton-oil; (2) blood poisons, as ricin; (3) poisons which kill without anatomic changes, as morphin, digitalin, and the like; and a fourth class may be added, (4) skin-irritants, as poison ivy.

The most poisonous lower plants are fungi belonging to the genus *Amanita*. The two most virulent are the toadstools, *Amanita muscaria*, which contains muscarin, and *A. phalloides* with phallin. Fortunately, an antidote has been discovered for the first in the administration of hypodermic injections of atropin beginning with 1-100 of a grain, and increasing the dose to a strength of 1-60 of a grain. For phallin, no antidote is known. Of the higher plants, the most noted poisonous ones are: *Aconitum Napellus* (monkshood); *Delphinium Geyeri* (larkspur); *Oxytropis Lambertii* and *Astragalus mollissimus* (loco weeds); *Rhus radicans* (poison ivy), which is a serious skin-irritant; *Rhus vernix* (poison

3089. Poison sumac.—*Rhus vernix*. ($\times \frac{1}{2}$)

sumac), which is also decidedly toxic to the skin; *Cicuta maculata* (cowbane), which contains two poisons conin and cicutoxin; *Conium maculatum*, the classic poisonous plant, from which came the death-draught of the philosopher Socrates; *Kalmia latifolia* and *K. angustifolia*, the two poisonous laurels; *Datura Stramonium* (Jamestown weed); *Atropa Belladonna* (deadly nightshade) and others too numerous to mention.

Popular interest usually attaches to the poison ivy, *Rhus radicans* or *R. Toxicodendron* (Fig. 3088), a root-climbing vine with ternate leaves, and the poison

sumac, *Rhus vernix* (Fig. 3089), with pinnate leaves. Both of these plants have white fruits and hence are easily distinguished from the non-poisonous sumacs. The poison ivy is everywhere in the eastern states along roads, fence-rows and uncultivated ground, while the poison sumac grows in swamps and is less common. Both are skin-irritants, causing what physicians call dermatitis. If the susceptible person thinks he has come into contact with the plants, he should wash his hands and face with alcohol, as this dissolves and removes the non-volatile oil, toxicodendrol. Smoke from a brushwood fire containing these plants is toxic, and so is the Japanese lacquer made from the inspissated juice of a sumac, *Rhus vernicifera*. Unfortunately, all parts of these plants are virulent and at all seasons of the year. One of the best remedies is an alcoholic solution of sugar of lead, and the extract of grindelia (sold at drug-stores) is sometimes used. Local remedies are fresh bean leaves, stems of touch-me-not (*Impatiens*) and plantain leaves (*Plantago lanceolata*). At least, these leaves allay the burning sensation of the inflamed skin. An authoritative work on toxic plants is the "Manual of Poisonous Plants," by L. H. Pammel, professor of botany in Iowa State College of Agriculture, in two parts, Part I (1910) and Part II (1911) with a total of 977 pages. Other publications have been issued.

Two plants much in prominence at the present time in Wyoming on account of their poisonous effect on livestock are discussed by H. G. Knight, as follows: "Woody aster, *Xylorrhiza Parryi* (Fig. 3090), is found throughout the state of Wyoming, but is confined to certain districts characterized by a gumbo clay soil, more or less intermixed with gravel and containing more or less of alkali and other salts. This plant probably causes greater losses among sheep in the state of Wyoming than all other poisonous plants together, but may be easily recognized by those familiar with the range. So far as is known, sheep are the only species of range animal susceptible to poisoning by woody aster. No antidote is known and there is much question whether a satisfactory antidote will be obtained as the action of the poison is powerful and death comes speedily with many pathological changes."

Pammel writes, "Death camas, *Zygadenus intermedius*, is a near relative of the better known *Zygadenus venenosus*. In Wyoming the most common species is the *Z. intermedius* and the greatest losses noted have occurred in early spring when the plant is in bloom, and before early forage is plentiful. The plant grows on the sandy plain as well as in the drier and stonier foothills. It has been found that the poisonous properties are due to the presence of alkaloids, one of which at least is new to science. An antidote has not as yet been determined."

JOHN W. HARSBERGER.

POIVREA (N. Poivre, 1719-86; intendant of Mauritius). *Combretaceæ*. Mostly climbing shrubs: lvs. opposite or alternate, entire; spikes axillary and terminal; calyx 5-lobed; petals 5; stamens 10, protruded; ovary 2-3-ovuled; fr. oval or oblong or 5-winged; seed solitary, pendulous, 5-angled. It includes a S. African shrub with orange-red fls. cult. in S. Fla. and Calif. The genus is referred by Bentham & Hooker to *Combretum*, a large genus containing some handsome plants that are little known. Poivre differs from the other combretums chiefly in the convolute cotyledons. *P. bracteosa*, Hochst. Unarmed shrub 8-10 ft. high: lvs. opposite or in 3's, $2\frac{1}{2}$ -3 x $1\frac{1}{2}$ in.; petals clawed, reddish, 4 lines long; fr. oval, indistinctly 5-angled. Called "hiccup-nut" in Cape Colony. *P. comoda*, Sweet. A large climber with great panicles of blood-red fls.: fr. short-stalked, notched at both ends. Trop. Afr. B.R. 1165 (as *Combretum comosum*).

POKER PLANT: *Kniphofia*.

POKEWEED: *Phytolacca*.

POLANÍSIA (Greek, *many, unequal*, referring to the stamens). *Capparidaceæ*. Annual herbs, mostly glandular and having an unpleasant odor: lvs. palmately 3-5-foliate, the uppermost reduced to bracts of the racemose fls.: fls. whitish or yellowish; sepals 4, lanceolate, deciduous; petals slender or clawed; receptacle depressed, bearing a gland at the base of the ovary; stamens 8 to numerous, somewhat unequal; fr. a nearly or quite sessile pod.—About 30 species, natives of temperate and tropical regions, of little value horticulturally. *P. trachysperma*, Torr. & Gray. A branched glandular-pubescent viscous annual, 1-2 ft. high: lvs. petioled, with 3 oblong lfts.: fls. yellowish white in terminal racemes, rather large: fr. a caps. more or less contracted at base, not stipitate. N. Amer. Intro. abroad.

POLEMONIUM (ancient name, not explained; probably not from Greek *polemos*, war, but rather the philosopher Poleman). **JACOB'S LADDER.** **GREEK**

3090. Woody aster (*Aster*, or *Xylorrhiza*, *Parryi*), a poisonous plant of the Plains.

VALERIAN. *Polemoniaceæ*. Flower-garden herbs, with pinnate leaves and pretty blue, purplish white or yellowish flowers.

Perennials, rarely annuals or biennials, tall or dwarf, often viscid, often with a creeping rhizome which is thick or slender: lvs. alternate, odd-pinnate or pinnatisect: fls. in racemes or thyrses-like panicles; calyx increasing after anthesis; corolla tubular, funnel-shaped, broadly bell-shaped or subrotate, 5-lobed, the lobes mostly obovate; stamens 5, alternate, with corolla-lobes inserted near the base, included or exserted: caps. 3-valved. Closely allied to *Gilia* and distinguished by the declinate stamens and the filaments usually pilose-appendaged at the base.—Brand, in the recent monograph (Engler's *Pflanzenreich*, IV. 250, hft. 27, 1907) accepts 29 species; mostly W. N. American, extending into Mex., but also in Eu., Asia and 2 in. S. Amer.

This genus includes the Jacob's ladder, *P. caeruleum*, an old-fashioned inhabitant of cottage gardens, which owes its popular name to the regular manner in which the numerous leaflets are arranged on the long leaves. It is a hardy perennial herb, growing 1 to 3 feet high and bearing five-lobed bell-shaped flowers of blue or white, and nearly an inch across. Probably the finest species, however, is the plant known to all gardeners as *P. Richardsonii*, which is a form of *P. humile* (or *P. lanatum*) that has doubled or trebled in size in cultivation. A fine specimen of *P. Richardsonii* may have a terminal cluster $6\frac{1}{2}$ inches across and 5 inches deep, with two dozen flowers each $1\frac{1}{4}$ inches across. *P. confertum* differs in the great density of its inflorescence, and by connoisseurs in alpine plants may be regarded as a very fine species. Most of the yellow-flowered forms are disappointing. Polemoniums are of easy culture in any deep rich loamy soil. *P. caeruleum* and *P. reptans* do well in partly shaded places not too dry.

Polemoniums are easily raised from fall-sown seed. Also propagated by division. They are said to be impatient of soil on the leaves.

INDEX.

album, 4, 9.	humile, 4.	pulcherrimum, 5.
caeruleum, 9.	lanatum, 4.	pumilum, 5.
carneum, 7.	mellitum, 3.	reptans, 6.
confertum, 2, 3.	occidentale, 9.	Richardsonii, 4.
foliosissimum, 8.	pauciflorum, 1.	Van-Bruntiae, 9.
grandiflorum, 9.	pulchellum, 4.	variegatum, 9.
himalayanum, 9.		

A. Corolla tubular or funnellform, the tube longer than the lobes.

1. **pauciflorum**, Wats. Perennial, erect and branched, somewhat villous, 1-2 ft.: lfts. 8-13 pairs, about 1 in. long; fls. yellowish, tubular, the tube $1\frac{1}{4}$ in. long, much longer than the lobes, solitary or loosely corymbose, long-pedunculate; stamens bearded at base, about equaling the corolla; caps. oblong. Mex.—The color is said to be a good clear yellow, tinged red outside. Offered by J. W. Manning in 1892, but subsequently dropped.

2. **confertum**, Gray. Perennial, with a thick woody rhizome, sticky, smelling of musk, 9-18 in. high: lfts. very small and so crowded as to seem whorled; infl. a dense head; fls. honey-scented, deep blue, $\frac{1}{2}$ -1 in. long; corolla narrowly funnel-shaped; filaments naked or nearly so and not dilated at base. Rockies and Sierras. Gn. 10:506. G.C. II. 24:12; III. 27:237. G.M. 55:459. G.W. 7, p. 356.—Intermediate between Polemonium and Gilia.

3. **mellitum**, A. Nels. (*P. confertum* var. *mellitum*, Gray). An attractive species with white or pale fls., the

3091. *Polemonium reptans*. The leaflets are often much broader. ($\times \frac{1}{2}$)

plant usually taller than *P. confertum* and the infl. more lax and leafy and becoming racemose or spike-like; corolla fully 1 in. long, the lobes only one-third or one-fourth the length of the tube; herbage heavily musk-scented, fls. honey-scented (whence the name). Rocky Mts. Nev. Gn.W. 25:557.

AA. Corolla campanulate to rotate, the tube mostly shorter than the lobes.

B. Plants low, with thickened rootstocks: lfts. seldom $\frac{1}{2}$ in. long.

4. **humile**, Willd. (*P. Richardsonii*, Graham). Low, slender plant from somewhat creeping rootstocks, about 9 in. high: lfts. 15-21, 2-6 lines long; fls. bell-shaped, blue or purplish. July, Aug. Arctic regions. B.M. 2800 (yellow eye). G.C. II. 19:793. B.R. 1303 (as *P. caeruleum* var. *piliferum*).—It has the odor of ripened grapes. Brand combines this plant with *P. lanatum*, Pallas, of the Arctic Zone and the Altai region, making this form *P. lanatum* var. *humile*, Brand, with a wide range in the high N. *P. Richardsonii*, referred here, was raised from seeds collected at Great Bear Lake. The plant cult. as *P. Richardsonii* grows about 18 in. high, and bears profusely of bright blue fls. (varying to white in var. *album*, Hort.); probably the best of the genus, and in need of botanical study. Aside from references above, portraits occur in Gn. 78, p. 615; G.M. 45:494; Gn.W. 5:757; J.H. III. 54:101.

Var. **pulchellum**, Gray (*P. pulchellum*, Bunge. *P. lanatum* var. *pulchellum*, Brand). Differs in having smaller fls. ranging from violet and lavender to nearly white and in the viscid pubescence, which is minute. Arctic coast and southward according to Gray, but restricted by Brand to Asia (Altai region).

5. **pulcherrimum**, Hook. (*P. pumilum* var. *pulchellum*, Rydb.). By Gray considered to be a more viscid lax or diffuse and small-fl. form of *P. humile* var. *pulchellum*, the corolla violet varying to white, and with narrower lobes. By Brand it is made to comprise the American forms passing as *P. humile* var. *pulchellum*, with much smaller fls.: sts. erect, more or less pilose and glandular-viscid, 10 or 12 in. or less high: radical lvs. numerous, the lfts. 17-27, small, ovate, obtuse and entire; st.-lvs. few: fls. in terminal corymbs, the corolla very variable, usually bicolored (blue with white tube), 5-8 lines long, the lobes oblong and much exceeding the short tube; caps. ovoid, much shorter than the calyx. High Rocky Mts. and northward. B.M. 2979. B.R. 1304 (as *P. humile*). Gt. 9:292 (as *P. pulchellum*).

BB. Plants weak and rather low, with a short rootstock: lfts. $\frac{1}{2}$ -1 $\frac{1}{2}$ in. long.

6. **reptans**, Linn. GREEK VALERIAN. Fig. 3091. Height 1 ft. or less: slender, weak and diffuse but never creeping (as the name would indicate): foliage not viscid or glandular; lfts. 5-15, from lance-oblong to broad-ovate, acute, entire; fls. light blue, $\frac{1}{2}$ in. across, in a loose panicle-like cluster terminating the st.; corolla $\frac{1}{2}$ - $\frac{3}{4}$ in. long in cult., about $\frac{1}{2}$ in. or more broad; calyx-lobes acute or obtuse; stamens not exerted; caps. about 3-seeded. Open woods, N. Y. to Ala., west to Minn. and Kans. April, May. B.M. 1887.—Said to be an easy prey to snails, especially in winter, when they attack the rootstocks.

7. **carneum**, Gray. St. lax or loosely branching, 1-2 ft. high, with a horizontal rootstock: lfts. 5-17, often $1\frac{1}{2}$ in. long, ovate to oblong-lanceolate; fls. salmon or flesh-color fading to purplish, $1\frac{1}{2}$ in. across, the corolla-lobes rounded-obovate; calyx deeply 5-cleft, with ovate-oblong lobes. Mountain woods, Calif., Ore. G.C. III. 48:134.—Offered in Ore., 1892, but probably not in cult. now. Closely allied to *P. reptans*.

BBB. Plants strong and erect, mostly tall, with slender rootstocks or roots: lfts. usually large.

c. Fls. not blue (seldom running to violet), yellowish, cream-color or salmon.

8. **foliosissimum**, Gray. Sts. solitary and erect, 1-3 ft. tall, simple or branched, hairy at base and viscid above, from a woody short rootstock: herbage strong-scented; lvs. many; lfts. lanceolate to ovate-lanceo-

late, usually less than 1 in. long: fls. commonly white or cream-colored, rarely violet, an inch or less long, corymbose-cymose, the corolla twice the length of the calyx; stamens and style not exerted: caps. nearly globose. Rocky Mts.—Cult. some years ago, but perhaps never offered in Amer.

cc. Fls. blue (to white).

9. *cæruleum*, Linn. JACOB'S LADDER. CHARITY. Fig. 3092. Stout perennial herb, erect and leafy, 1-3 ft.: st. lightly hairy or nearly smooth, more or less glandular, angled: radical lvs. forming dense tufts, on petioles 6 in. or more long, the lfts. 11-21, lanceolate and mostly acuminate, entire; st.-lvs. smaller, very short-petioled or sessile near top of st.: fls. blue, many drooping in a panicle (frs. erect), 1 in. or less diam., the stamens not exerted; style protruded; corolla-lobes broad and spreading, subacute or mucronulate; calyx campanulate, with oblong acute lobes: caps. included in the calyx. Eu., mostly in copses and along streams, in moist or wet ground. Var. *album*, Hort. (*P. album*, Hort.), with white fls., is almost as popular as the type. Var. *variegatum*, Hort., has variegated foliage. There is also a dwarf form.—*P. cæruleum* is widespread and variable, and the geographic forms are sometimes set off as species. Var. *himalayanum*, Baker (*P. himalayānum*, Baker. *P. grandiflorum*, Hort., not Benth. *P. cæruleum* var. *grandiflorum*, J. W. Manning), is the Himalayan form, with large fls. $1\frac{1}{2}$ in. across, lilac-blue or darker, the rounded lobes nearly $\frac{1}{2}$ in. across; calyx and axis of panicle very hairy. In separating the American forms, much is made of the character of the rootstock. Greene, who has studied them, describes the true *P. cæruleum* of Eu. and of gardens as having a tap-root surmounted by a stout short simple or branching very leafy crown standing above ground. Hooker, however, speaks of the rootstock as short, creeping. The E. American representative, native in cold swamps and along streams, Vt. to Md., and probably not in regular cult., is now separated as *P. Van-Bruntiae*, Brit.; from *P. cæruleum* it differs in having horizontal stout rootstocks, more leafy st., exerted stamens, rounded (not mucronulate) petals, accrescent calyx which becomes twice or three times the size of that of *P. cæruleum*, broader and fewer lfts., and fewer ovules. It bears considerable resemblance to *P. reptans*, but that species has a diffuse habit, fls. half the size, stamens included and calyx lobed only about one-third its length, the lobes obtuse. This species bears the name of Mrs. Van Brunt. The Rocky Mountain representative is separated as *P. occidentale*, Greene, differing from *P. cæruleum* in having slender rootstocks, upper part of st. viscid-pubescent, lfts. narrower, lanceolate, stamens only the length of the corolla, the fruiting calyx not nearly so large and the lobes obtuse or obtusish.

L. H. B.†

3092. *Polemonium cæruleum*.

POLIANTHES (name discussed below). *Amaryllidaceæ*. TUBEROSE. Tender summer-flowering bulb, producing long spikes of very fragrant blossoms; by successional plantings, it may be had at different seasons; commonly double-flowered.

Developed lvs. mostly basal, those on the st. short: perianth white; tube long, narrowly funnel-shaped, curved; segms. short, subequal; stamens affixed at the middle of the tube, not exerted; ovary 3-celled, free at apex; stigmas 3, ovate, falcate: fr. crowned by the persistent perianth; seeds flat.—As defined by Rose (1903), the genus contains about a dozen species, Mexican, and Bravoa is not clearly distinct. The common tuberose, *P. tuberosa*, is unknown in a wild state; if it had its origin from any of the Mexican species, it must have come from *P. gracilis*. Possibly it is native in the Andes of S. Amer.

The name Polianthes was given to the tuberose by Linnæus in 1737 in his "Genera Plantarum." Unfortunately he wrote "Polyanthes" in another work, published in 1737. This was probably an error. Some writers have changed the spelling to Polyanthus, supposing that Linnæus had in mind the idea of "many-flowered," from *polys* and *anthos*. Others have supposed he derived it from *polis*, a city. It seems probable, however, as Bentham & Hooker suggest, that Linnæus had in mind *polios*, "shining," "white," and *anthos*, "flower," which is much more applicable to the tuberose than are the other derivations. Consult *Polyanthus* for other meanings of the word Polyanthus. The name "tuberose" is derived from *tuberosa*, this plant being the tuberous hyacinth as distinguished from the bulbous hyacinth. The name therefore is *tuber-ose*, not *tube-rose*.

tuberosa, Linn. TUBEROSE. Fig. 3093. Rootstock tuberous: sts. in clusters, 2-3½ ft. high: basal lvs. 6-9 to a st., 1-1½ ft. long, ½ in. or less wide, bright green, reddish near the base: st. with 8-12 reduced lvs.: fls. 1½-2½ in. long, pure waxy white, borne in pairs in a lax spike; segms. ½-¾ in. long, the tube bent only near the base; filaments attached on upper part of corolla. B.M. 1817. B.R. 63. R.H. 1882, p. 429. F. 1881, p. 27. Gn. 47, p. 330. It runs into double forms. Gn.W. 16:10.

P. Blasii, Hort., is a garden hybrid between Bravoa geminiflora and *P. tuberosa*.—*P. gracilis*, Link & Otto (*P. tuberosa* var. *gracilis*, Baker), supposed to be Mexican, is distinguished by slender habit and narrower lvs.: perianth-tube long and slender; segms. linear. Possibly the original form of *P. tuberosa*.—*P. maculata*, Mart., is a Manfreda (p. 1983).

L. H. B.†

Culture of the tuberose for bloom.

There are only two objections to the tuberose: its odor is too powerful for many persons, and, like the calla lily, it has funeral associations. Therefore, fashion has deserted it, at least in North America. Nevertheless great quantities of the bulbs are grown in this

country, and a good part of them are used here as well as exported. The tuberose is more popular than ever in Europe. It will always be a standard florists' flower, for the people like it, whatever fashion may decree.

For the home garden, the bulbs are best procured in spring and planted outdoors after all danger of frost is over. The common tall-growing double sort is preferred for this purpose, largely because the fls. open better during the unfavorable dry weather which often occurs in October. Cover the bulb about an inch with fine light soil. A bulb planted out June 1 will bloom in late summer or fall. Before frost comes, take up the bulbs and store them over winter in a rather warm (50° F.) dry place where no frost will touch them. If kept moist and cool during winter the bulbs are likely to rot at the center. Sound tubers will always be green at top or show some sign of life at the growing-point. The others are not worth planting. In the far North where the season is short, tuberose bulbs may be started indoors about the middle of May, the tubers being placed on a layer of damp moss.

By florists, tuberoses are chiefly grown for summer and fall bloom. It is very difficult to force tuberoses so as to bloom from January to March, but they can be forced with comparative ease to bloom from April to June. Also flowers may readily be secured for November and December by retarding the bulbs. In forcing, the bulbs are started about the first of January, being placed close together in boxes only 3 inches deep, with 2 inches or so of moss on the bottom. These boxes are placed over the pipe where a temperature of 75° may be maintained. In four to five weeks the tubers will have sent roots all through the moss, and they should then be potted in 4- to 5-inch pots, or planted in a bench containing 4 or 5 inches of soil. The temperature should never be less than 75°, and 80° is better. For May and June bloom, successional batches may be planted at intervals of three or four weeks after New Year. The last crops will usually be the best.

For November florists' bloom the bulbs are retarded in a cool dry place until the middle of August. The second batch should not be planted until about the middle of September. This lot should give good December bloom.

For summer blooming in the open ground for florists, the form known as the "Tall Double" is the most to be preferred. In this variety, the flowers open better and are a clearer and purer white than those of the Pearl. The Albino is a single white tuberose, blooming in July and August. It is a very floriferous variety, with flowers that lack the brown or stained tint of some of the older forms. The odor is less powerful, and therefore more pleasant, than that of the ordinary tuberose. There are several interesting forms.

PETER HENDERSON & Co.

Commercial production of tuberose bulbs.

Tuberose bulbs were formerly grown extensively for commercial purposes in Italy, and are grown in a small way at the present time in South Africa, although the African bulbs are not in much favor with European florists because the bulbs ripen and are shipped in mid-summer and a great number fail to bloom. The foreign-grown bulbs are not imported into the United States and, owing to the superiority of the American-grown tuberose and the low price at which they are produced, they have driven the Italian-grown bulbs out of the American market. About 80 per cent of the American crop is exported. The larger part of the product of this country is grown in a limited area in the southeastern part of the state of North Carolina, although there has been some falling off in recent years.

Tuberose bulb-culture in the southern states was first attempted by F. A. Newbury in Duplin County, North Carolina, in 1868. Beginning with a dozen bulbs, he propagated stock until, in 1888, the yield was about 1,000,000 bulbs. During these years the crop was cultivated entirely by hand and consequently was very expensive. The prices received at first were \$40 a 1,000, but since then prices have declined each year as quantity increased until, in 1888, bulbs were selling at \$6 to \$8 a 1,000, and in 1915 at \$5 to \$7. In 1888, the late H. E. Newbury, a brother, bought out the business, and he and J. F. Croom, another

grower who had propagated considerable stock, extended the business greatly, introducing less expensive methods of cultivation. By use of the horse-plow they were enabled greatly to reduce the selling price and to stimulate demand for bulbs, so that the crop of 1900, within a radius of 20 miles of one point (Magnolia, North Carolina), amounted to 6,000,000 bulbs, selling at wholesale in carload lots at \$3.50 a 1,000. This yield was secured from over 300 acres. The total yield of the American-grown stock in 1915 was probably about 2,000,000 first-size bulbs.

The crop is set in April, after the soil has been thoroughly pulverized. It is then laid off in rows or furrows 22 inches apart; into these is sown fertilizer at the rate of 600 pounds to the acre. About 400 pounds of cottonseed-meal and 20 bushels of good wood-ashes to the acre have given the best results, although any reliable fertilizer with a good percentage of potash is good. The fertilizer is thoroughly mixed with the soil by running a plow with point only in the furrow. Into this the sets or "seed," as they are called, are carefully placed upright by hand and covered with plow. Usually the bulblets are rather slow in starting off, and just as they begin to break through, the soil, which has become hardened or crusted, is raked or broken up. This assists the plant in getting up and also destroys any growth of grass which may have started. Cultivation is performed chiefly with a cotton-plow, using the sweeps to put earth to the plant and destroying any grass in the rows. Tillage is required every two weeks until August; an occasional hoeing between plants by hand is necessary in order to loosen the soil and destroy weeds and grass not reached by the plow. The crop is matured and gathered between October 15 and November 15. The tops by this time have reached a length of 18 to 20 inches; these are cut off at the ground with a sharp weeding-hoe and the bulbs are plowed out very much as potatoes are. Women then lift out and shake off the earth, and the offsets are removed by hand. These sets are the seed-stock for next season. The bulbs are graded

3093. *Polianthes tuberosa*. (× 1/4)
